A DICTIONARY OF ARTS AND SCIENCES.

BY G. GREGORY, D.D.

IN TWO VOLUMES.

VOL. II.

LONDON:
PRINTED FOR RICHARD PHILLIPS,
NO. 6, BRIDGE-STREET, BLACKFRIARS.

1807.

T. Gillet, Printer, Wild-Court.
TO THE RIGHT HONOURABLE

THOMAS, LORD ERSKINE,
BARON ERSKINE OF RESTORMEL CASTLE, IN THE COUNTY OF CORNWALL,
LORD HIGH CHANCELLOR OF GREAT BRITAIN,

&c. &c. &c.

MY LORD,

THOUGH a Dedication is in general an expression of gratitude from an Author to his Patron, or of friendship from one literary character to another, yet I cannot but be of opinion, that there should be some accord between the character of the Work and that of the Patron to whom it is presented.

In this point of view the world will see the propriety of a Work which professes to treat of the Sciences and the Arts in general, being inscribed to a Nobleman who unites in himself more various, as well as more splendid talents, more general knowledge, and more diversified taste, than any other public character of the present age; who, deservedly filling the chair of Bacon, possesses the same excursive and expanded genius; but whose public duties, being more onerous than they were in the time of that great man, alone preclude him from gratifying and enlightening the Public by researches out of the line of his profession.

VOL. I.
DEDICATION.

If a private sentiment might be indulged on such an occasion, the Editor would add, that your Lordship's unremitted zeal for true Religion, and your tried and disinterested Patriotism, must for ever endear the name of Erskine to every friend of liberty, piety, and active virtue.

That your Lordship may long continue to serve your country, and promote the best interests of humanity, in the arduous situation to which the Divine Providence has been pleased to call you, is the fervent prayer of,

My Lord,

Your Lordship's

Ever faithful humble servant,

G. GREGORY.

West Ham, Jan. 20, 1807.
PREFACE.

FROM the time of Chambers, Dictionaries of Arts and Sciences have been increasing in magnitude, without (it is to be feared) a proportionable increase of utility. The authors appear to have regarded it as a kind of sacrilege to retrench, while they have equally thought it their duty to add every thing that came within their reach. Hence not only obsolete terms, but obsolete sciences, as magic, alchemy, and astrology, have been retained even in works of high character, and otherwise of distinguished merit. Hence, that which was new even in the living sciences, has been combined with what had been long since exploded: a practice calculated not only to confuse but to mislead.

It was upon this view of the subject it occurred to the editor of this work, that in framing a new Dictionary, selection was a more urgent duty than accumulation; that perspicuity, not less than convenience, would be consulted by reducing the size; and that whatever is practically useful in science and in art might be compressed within a smaller compass than had been commonly imagined. However deficient he may have been in the execution of his plan, he has the satisfaction to say, that in this idea he was not deceived or disappointed.

A dictionary of this kind is intended for two purposes: first, as a book of reference, to lie on the table of a man of letters, for occasional consultation where recollection has failed, or where a subject occurs in reading or conversation which had not previously come within the course of his studies. The second is, to serve as an introductory or elementary work for students, or for those who may not have leisure to bestow on the great works of science, or to travel through the many volumes which at this time almost every branch of knowledge includes.

The first of these ends it is Humbly presumed will be sufficiently answered by the present publication. Most of the technical terms in science and the arts, are inserted with a proper definition or explanation, in the alphabetical order; or should there be a casual omission, the word will still be found under the head of the science to which it belongs, and probably in the index to the treatises at the end of each volume. To some sciences it was found necessary to attach a glossary. The technical phrases, however, in anatomy, surgery, &c. are generally referred to those branches of science expressly treating of them, that nothing may appear, on casually opening the book, to offend the most modest or delicate reader. Terms also which now constitute a part of common colloquial language, and which, therefore, every person must understand, have been omitted.

With respect to the second object, no pains have been spared in preparing those articles which treat of the respective sciences. In a work of this nature it cannot be expected that the whole should be original, nor could it in that case answer so well the ends for which it is designed. An Encyclopedia is in its nature a compilation; and its best commendation is, that it amasses together the best,
information from the best sources. Yet in this work there is much original composition; and such is the progress of science, that it contains scarcely any articles of importance which are to be found in any similar publication.

In order also to facilitate as much as possible the study of the sciences, every attention, consistent with the nature of the work, has been paid to method; and the student will not be much at a loss to distinguish the order in which the several parts of each science are to be read. Thus, under Natural History, he will find a synopsis of the several branches, the classes and orders, and under these the names of the genera; under Zoology, again, he will not only meet the classes and orders, but also an immediate reference to the genera. Under Chemistry, he will find the outlines of the science, and references to the different branches, which are treated more at large in other parts of the work. Thus under Furnace and Laboratory, is included the whole of the apparatus; and he will then turn to Air, and the simple substances as they stand enumerated there, or under the word Elements. Astronomy and Mineralogy, he will see, have similar references. Electricity, Hydrostatics, Hydraulics, Magnetism, Mechanics, Meteorology, Optics, Pneumatics, and the Medical Branches, are complete in themselves. Those articles which relate to the Arts are also complete. Those which treat of the different subjects of Trade and Commerce are also complete, and contain all the new information which could be obtained on those important topics.

The Editor cannot conclude this address without frankly stating, that whatever may be thought of the merits of the new Dictionary of Arts and Sciences, they are more to be attributed to the very able assistance with which he has been favoured from different quarters, than to his own exertions. He wishes he could make his acknowledgments in terms equal to his sense of the obligation. To his industrious and truly able coadjutor, the Rev. Mr. Joyce, he is indebted for much general assistance, and for the exclusive superintendence of all the mathematical and astronomical articles. A similar acknowledgment is due to his friend and neighbour, Luke Howard, Esq. particularly for his attention to all those articles connected with the almost new, and important science, Meteorology.

The public will estimate better than he can point out the extent of his and their obligations to Mr. Grellier, of the Royal Exchange Assurance-Office, when he mentions, that all the articles relative to Trade, Commerce, Political Economy, Finance, and Revenue, were drawn up by that gentleman.

The Medical and Physiological articles were written by Dr. Uwins, of Somers Town; Husbandry and Surveying by Mr. Crocker, of Froome; Rhetoric by Dr. Thomson, well known as the Continuator of Watson’s History; Architecture by Mr. Henderson, the plates by Mr. Moore; Exchanges by Mr. P. Hamsbrow; Farriery by Mr. Lawrence; and Anatomy by Mr. A. Walker.

Those articles which are connected with History and Antiquities, have been furnished by a distinguished scholar, as will be easily perceived; those relative to the Fine Arts, by a gentleman well known in the literary world; Poetry by a lady, who, like Vida, has asserted her title to the character of a critic, by having excelled in the art itself; the Military articles are the production of a literary gentleman who was educated in that profession; and some of the principal Law articles are by a member of one of the inns of court. Besides these, the editor has been favoured with single communications from Dr. Mavor, Mr. M. Smart, and several correspondents who desire their names to be concealed.
DICTIONARY
OF
ARTS AND SCIENCES.

JAC

I, the ninth letter of the alphabet, used as a numeral, signifies no more than one, and stands for so many units as it is repeated times: thus, I, one; II, two; III, three, &c., and when put before a higher numeral, it subtracts itself, as IV, four; IX, nine, &c., but when set after it, so many are added to the higher numeral, as there are Ps added: thus VI is 5 + 1, or six; VII, 5 + 2, or seven; VIII, 5 + 3, or eight. The ancient Romans likewise used C for 100, CL for 100, CXC for 200, CC for 300, CCC for 500, and CCCCL for 100, 000. Farther than this, as Pliny observes, they did not go in their notation; but when necessary, repeated the last number, as CCCCLXX, CCCCLXXX, CCCCLXXXX, and so on.

JACK, in mechanics, an instrument in common use for raising heavy timber, or very great weights of any kind, being a powerful combination of teeth and pinions, and the whole inclosed in a strong wooden stock or frame BC, and moved by a winch or handle HP; the outside appearing as in Plate Miscel. fig. 131. In fig. 132, the wheel or rack work is shown, being the view of the inside when the stock is removed. Though it is not drawn in the just proportions and dimensions, for the jack AB must be supposed at least four times as long in proportion to the wheel Q, as the figure represents it; and the teeth, which will be then four times more in number, to have about three in the inch. Now if the handle HP is seven inches long, the circumference of this radius will be 44 inches, which is the distance or space the power moves through in one revolution of the handle; but as the pinion of the handle has but four leaves, and the wheel Q supposes 20 teeth, or five times the number, therefore to make one revolution of the wheel Q, it requires five turns of the handle, in which case it passes through 5 times 44 or 220 inches; but the wheel having a pinion R of three leaves, these will raise the rack three teeth, or one inch, in the same space. Hence, then, the handle or power moving 220 times as fast as the weight, will raise or balance a weight of 220 times its own energy.

And if this is the hand of a man who can sustain 50 pounds weight, he will, by the help of this jack, be able to raise or sustain a weight or force of 11000 pounds, or about 5 tons weight.

This machine is sometimes open behind from the bottom almost up to the wheel Q, to let the lower claw, which in that case is turned up as B, draw up any weight. When the weight is drawn or pushed sufficiently high, it is kept from going back by hanging the end of the hook S, fixed to a staple, over the curved part of the handle at H.

The Society of Arts rewarded Mr. Moock of Southwark, with a premium of 20 guineas, for his contrivance to prevent a jack from taking a retrograde course whenever the weight by any accidental circumstance overbalances the power. The improved jack only differs from those in common use in this respect, that it has a pall or clock, and ratchet, applied in such manner as to stop the motion of the machine as soon as it begins to run back again. As the difference in the mechanism is very trifling, the improvement may be easily applied to any common jacks already made.

JACK is also the name of a well-known engine in the kitchen, used for turning a spit. Here the weight is the power applied, acting by a set of pulleys; the friction of the parts, and the weight with which the spit is charged, are the forces to be overcome; and a steady uniform motion is maintained by means of a fly.

The common worm-jack is represented at Plate Miscel. fig. 136. ABC is the barrel round which the cord QR is wound; KL the main wheel, commonly containing 60 teeth; N the worm-wheel of about thirty teeth, cut obliquely; LM the pinion, of about 15; O the worm or endless screw, consisting of two spiral threads, making an angle of sixty or seventy degrees with its axis; X the stud, and Z the loop of the worm-spiral; P a heavy wheel or fly, connected with the spindle of the endless screw to make the motion uniform; DG the struck wheel fixed to the axis FD; S, S, S, are holes in the frame, by which it may be nailed to a board, and thence to any wall, the end D being permitted to pass through it; HI the handle going upon the axis ET, to wind up the weight when it has run down. R is a box of fixed pulleys, and V a corresponding one of moveable, pulleys carrying the weight. The axis ET is fixed in the barrel AC, which axis being hollow, both it and the barrel turn round upon the axis FD, which is fixed to the wheel KL, when it turns in the order BT3; but cannot move in the contrary way, by reason of a catch nailed to the end AB, which lays hold of the cross-bars in the wheel IK.

The weight by means of the cord QR, in consequence of its descent, carries about the barrel AB, which by the action of the catch carries the wheel KLM, and this moves the pinion LM and wheel N, the latter moving the worm O and the fly P. Also the wheel LM carries the axis FD with the wheel DG, which carries the cord or chain that goes around the wheel or pulley at the head of the spit. But when the handle H gives motion to the axis in a contrary order to that given by the weight, the catch is depressed; so that although the barrel BC moves and winds the cord upon it, the wheel DG continues at rest. The time which the jack will continue in motion depends upon the number of pulleys, at R and V; and as these increase or decrease, so must the weight which communicates the motion, in order to perform the same work in the same time.

JACK, smoke, is an engine used for the same purpose as the common jack; and is so called from its being moved by means of the smoke, or red-heat air, ascending the chimney, and striking against the sides of the horizontal wheel AB (Plate Miscel. fig. 129), which being inclined to the horizon, is moved about the axis of the wheel, together with the pinion C, which carries the wheels, D and E; and E carries the chain F, which turns the spit. The wheel AB should be placed in the narrow part of the chimney, where the motion of the smoke is swiftest, and where also the greatest part of it must strike upon the sides. The force of this machine depends upon the draught of the chimney, and the strength of the fire.

Smoke-jacks are sometimes moved by means of spiral flyers, rolling about a vertical
axe; and at other times by a vertical wheel with sails like the float-boards of a mill; but the above is the more customary construction.

JACK-FLAG, in a ship, that hoisted up at the stern in the normal head.

JACKALL. See CANTS.

JACOB'S STAFF, a mathematical instrument otherwise called cross-staff. See Cross.

JACOBITISM, in church history, a sect of Christians in Scotland, and Mesopotamia; so called either from Jacob, a Syrian, who lived in the reign of the emperor Marcus; or from one Jacob, a monk, who flourished in the year 510.

JACOBUS, an ancient gold coin worth twenty-five shillings.

JACQUINIA, a genus of the monogyria order, in the hexadactyla class of plants; and in the natural method ranking with those of which the order is doubtful. The corolla is deciduous; the seed is inserted into the receptacle; the berry monomerosus. There are four species, shrubs of South America.

JADE-STONE, lapis nephriticus, or Jasper-chalcedony, a genus of siliceous earths. It gives fire with ease, and is transparent like flint. It does not harden in the fire, but melts in the focus of a burning-glass into a transparent green glass with some bubbles. A kind brought from the river of the Amazons in America, and called circumcension stone, melts more easily in the focus into a brown opaque glass, far less hard than the stone itself. The jade-stone is unctuous to the touch; whence Mr. Kirwan seems to suspect, that it contains a portion of argillaceous earth, or rather magnesia. The specific gravity is from 2.970 to 3.399; the texture granular, with a greasy look, but exceedingly hard, being superior in this respect even to quartz itself. It is infusible in the fire, nor can it be dissolved in acids without a particular management; though M. Sarsme seems to have extracted iron from it. Sometimes it is met with a whitish milky colour from China; but mostly of a deep and pale green from America. The common lapis nephriticus is of a grey, yellowish, or olive colour. It has its name from a supposition of its being capable of giving cause of vomiting by being applied externally to the loins. It may be distinguished from all other stones by its hardness, senilpelliuvity, and specific gravity.

According to Hopper it is composed of,

100.

JALAP, jadapa, in botany, a plant of the psuedantra monogyria class. See Convolvulus, and Materia Medica.

JAMHIC, in ancient poetry, a sort of verse, so called from its consisting, either wholly or in great part, of tactuals.

JAMBUS, in ancient poetry, a simple foot consisting of short and long syllables.

JAMES, or knights of St. James, a military order in Spain, first instituted about the year 1170, by Ferdinand II. king of Leon and Galicia.

JANIZARIES, an order of the Turkish infantry, reputed the grand signior's guards, and the main strength of the Ottoman army.

JANSENSISTS, in church-history, a sect of the Roman catholicks in France, who followed the Jansenius, viz a Jesuit of Ypres, and doctor of divinity of the universities of Louvain and Douay, nearly those of Calvin, in relation to grace and predestination.

JAPANNING is properly the art of varnishing and painting ornaments on wood, in the same manner as is done by the natives of Japan in the East Indies.

The substances which admit of being japanned are almost every kind that are dry and rigid, or not too flexible; as wood, metals, leather, and paper, prepared for the purpose.

Wood and metals do not require any other preparation, but to have their surfaces perfectly even and clean; but leather should be securely strained, either on frames or on boards; as its bending, or forming folds, would otherwise crack and force off the coats of varnish. Paper should be treated in the same manner, and have a previous strong coat of size; but it is made the subject of japanning till it is converted into paper mache, or wrought by other means into such form, that its original state, particularly with respect to flexibility, is changed.

One principal variation from the method formerly used in japanning is, the omitting any priming, or undercoat, on the work to be japanned. In the older practice, such a priming was always used; the use of which was to save in the quantity of varnish, by filling up the inequalities in the surface of the substance to be varnished. But there is a great inconvenience arising from the use of it, that the Japan coats are constantly liable to be cracked, and peeled off, by any violence, and will not endure near so long as the articles which are japanned without any such priming.

Of the materials of Japan grounds.—When a painting is to be japanned, the work should first be prepared by being well smoothed with fishskin or glass-paper, and being made thoroughly clean, should be brushed over once or twice with a mixture of three parts of water, two of third's varnish, in it is of the common strength. The priming should then be laid on as even as possible, and should be formed of a size, of a consistency between the common kind and glue, mixed with as much whiting as will give it a sufficient body of colour to hide the surface of whatever is laid upon, but not more. This must be repeated till the inequalities are completely filled up, and then the work must be left off with Dutch-rushes, and polished with a wet rag.

When wood or leather is to be japanned, and no priming is used, the best preparation is to lay two or three coats of coarse varnish, composed in the following manner.

Take of rectified spirit of wine one pint, and of coarse seed-lac and resin each two ounces; dissolve the seed-lac and resin in the spirit, and then strain off the varnish.

This varnish, as well as all others formed of spirit of wine, must be laid on in a warm place; and it can be conveniently managed, the piece of work to be varnished should be made warm likewise; and for the same reason, all dampness should be avoided; so either cold or moisture will hinder this kind of varnish, and prevents its taking proper hold of the substance on which it is laid.

When the work is so prepared, or by the priming with the composition of size and varnish, the proper Japan ground must be laid on, which is the best formed of seed-lac varnish, and the colour desired, except white, which requires a peculiar treatment; and if brightness is wanted, then also other means must be pursued.

The colours used with the shell-lac varnish may be any pigments whatever, which give the tint of the ground desired.

As metals never require to be under-coated with varnish, they may be treated in the same manner as wood or leather.

Method of painting Japan work.—Japan work ought properly to be painted with colours in varnish; though, for the greater dispatch, and in some very nice work in small, and where the colours are sometimes tempered in oil; which should previously have a fourth part of its weight of gum animi dissolved in it; or in default of that, a gum sandrachus, or gum mastich. The colour employed in this way, for painting, are best prepared by means of thinning size, corrected by honey or sugar-candy. The body, of the which the embossed work is raised, need not, however, be tinged with the exterior colour, but may be best formed of very strong gum-water, thickened to a proper consistence by bole armeniun and whiting in equal part; which being laid on the proper figure, and repaired when dry, may be then painted with the proper colours, tempered with the size above, or, in the usual manner, with shell-lac varnish.

Manner of varnishing Japan work.—The finishing of Japan-work depends on the laying on, and polishing, the outer coats of varnish which are necessary, as well in the pieces that have only one simple ground of colour, as with those that are painted. This is done best with common seed-lac varnish, except in the instances, and on those occasions, where particular methods are deemed to be more expedient; and the same reasons which decide as to the fitness or impropriety of the varnishes, with respect to the colours of the ground, hold equally with regard to those of the painting. For where brightness is the most material point, and a tinge of yellow will injure it, seed-lac must give way to the whiter gums; but where hardness and a greater tenacity are most essential, it must be adhered to; and where both are necessary, it may be proper one should give way to the other in a certain degree reciprocally, a mixed varnish must be adopted.

This mixed varnish, as we have already observed, should be made of the picked seed-lac. The common seed-lac varnish,
which is the most useful preparation of the kind hitherto invented, may be thus made.

Take of seed-lac three ounces, and put it into water, to free it from the sticks and filth that are frequently intermixed with it; and it should be done by stirring it about, and then pouring off the water, and adding fresh quantities, in order to repeat the operation, till it is freed from all impurities, as is very effectually done by this means. Dry it then, and powder it grizzly, and put it, with a pint of rectified spirit of wine, into a bottle, of which it will not fill above two-thirds. Shake the mixture well together, and place the bottle in a gentle heat, till the seed-lac appears to be done, as is done by rubbing it with a rag dipped in tripoli, or rottenstone, finely powdered; but, towards the end of the rubbing, a little oil of any kind should be used along with the powder; and when the work appears sufficiently bright and glossy, it should be well rubbed with oil alone, to clean it from the powder, and give it a still brighter lustre.

JARJON. See Zircon.

JASIONE, a genus of the monogynia order, in the syngnesia class of plants, and in the natural method ranking under the 44th order, campanaceae. The common calyx is ten-veined; and the corolla has five regular petals; the capsule beneath, two-celled. There are four species, shrubs of the Western ladies.

JASMINUM, JASMINE, or JESSAMINE, a genus of the monogynia order, in the diandra class of plants, and in the natural method ranking under the 44th order, separiae. The corolla is salver-shaped, the berry dicococcus; the seeds arillated, the anther within the tube. There are 17 species. The most remarkable are: 1. The officinalis, or common jasmine, which has long slender stalks and branches, rising upon supports 15 or 20 feet high, with numerous white flowers from the joints and ends, of a very fragrant colour. There is a variety with 2. striped jasmine, another with yellow-striped leaves. 2. The fractus, or shrubby yellow jasmine, has shrubby, angular, trailing stalks and branches, rising upon support eight or ten feet high; trifoliate and simple alternate leaves; with yellow flowers from the sides and ends of the branches, appearing in June; frequently producing berries of a black colour. This species is remarkable for sending up many suckers from its roots, often so plentifully as to form the ground, if not taken up annually. 3. The humilis, or dwarf yellow jasmine, has shrubby firm stalks, and angular branches, of low, somewhat robust and bushy growth; broad, trifoliate, and pin-nated leaves; and large yellow flowers in July, sometimes succeeded by berries. 4. The glandulorum, or greater-flowered Catalonian jasmine, has a shrubby, firm upright stem, branching out into a spreading head from the ground, rising about three to six or eight feet high, with large flowers of a blue-cored colour without, and white, appearing from July to November. Of this there is a variety with semidouble flowers, having two series of petals. 5. The azorium, or azorian white jasmine, has shrubby, long, slender stalks and branches, rising upon supports 15 or 20 feet high, with pretty large flowers of a pure white colour, coming out in loose bunches from the ends of the branches, and appearing in February. The odoratissimum, or most sweet-scented yellow Indian jasmine, has a shrubby upright stalk branching erect, without support, six or eight feet high, with bright yellow flowers in bunches, from the ends of the branches, flowering from July till October, and emitting a most fragrant odour.

The first three species are sufficiently hardy to thrive in this climate without any shelter. The other three species, which are tender, may be increased by layers or suckers, or by grafting and budding them upon the common white and shrubby yellow jasmine. They require shelter in a greenhouse in winter, and the more must always be kept in pots to move them out and in occasionally.

JASPER. This stone is an ingredient in the composition of many mountains. It occurs usually in large amorphous masses, sometimes in rounded or angular pieces. Its fracture is conchoidal, and its colours vary from yellow to 2.3 to 2.7. Its colours are various. When heated, it does not decrepitate. It is usually divided into 4 sub-species.

1. Egyptian jasper. A variety is found chiefly in Egypt. It usually has a spherical or flat-rounded figure, and is enveloped in a coarse rough crust. Specific gravity 2.784 to 2.7. It is chiefly distinguished by the variety of colours which always exist in the same specimen, in concentric stripes or layers. These colours are different browns and yellows, greens, &c.

2. Striped jasper. This variety is also distinguished by concentric stripes or layers, of different colours; these colours are yellow, brownish-red, and green. It is distinguished from the last variety by its occurring in large amorphous masses, and by the disposition of its stripes.

3. Porcelain jasper. So called because its fracture presents the appearance of porcelain. Its colours are various shades of grey, yellow, red, brown, green, mixed together. Found in mass, and in rounded pieces. Greasy. Fracture imperfectly conchoidal; opaque. According to Rose it is composed of: 60.75 silica, 27.25 alumina, 3.60 magnesia, 2.50 oxide of iron, 3.60 potash.

97.10

Found in the neighbourhood of pseudo volcanoes, supposed to have been altered by the action of fire.

4. Common jasper. Specific gravity from 2.53 to 2.7. Its colours are different shades of white, yellow, red, brown, and green; often variegated, spotted, or veined, with several colours.

JATROPIA, the cassava plant, a genus of the monadophila order, in the monoea class of plants, and in the natural method ranking under the 35th order, tricoeae. There is a rare variety of the corolla is hypetalous, and funnel-shaped; there are ten stamens, one alternately longer than the other. There is no male calyx; the corolla is pentatemenous and patent; there are three bud
extremities; the capsule is trilocular, with one seed in each cell. There are nine species, of which the most remarkable are: 1. The curar, or English physic nut, with leaves shaped like those of the cardoon, is a hairy shrub growing about 10 or 12 feet high. The extremities of the branches are covered with leaves; and the flowers, which are of a green herbaceous kind, are set in an umbel fashion round the extremities of the branches, but especially the main stalks. These are succeeded by many fruits, whose outward tegument is green and husky, which being peeled off discloses the nut, whose shell is black, and easily cracked; this contains an almond-like kernel, divided into two parts, between which separation lie two milk-white thin membranaceous leaves, easily separable from each other. These have not only a bare resemblance of perfect leaves, but have in particular every part, the stalk, the middle rib, and transverse ones, as visible as any leaf whatsoever. 2. The gossypifolia, cotton-leaved jatropha, or belly-ache bush; the leaves of which are quinquangular, the flowers in terminal, irregular, bracteate bobs. The stem, which is covered with a light-greyish bark, grows to about three or four feet high, soon dividing into several wide-extended branches. From amongst these sprout a few carill small daisy-purple petals, the pistil of each being thick-set at the top with yellow carinaceous dust, which blows off when ripe. These flowers are succeeded by hexagonal husky bladders, which are opened by the heat of the sun, emitting a great many small dark-coloured seeds, which serve as food for ground doves. 3. The multiform, or French physic-nut, with leaves many-parted and polished. The flowers of this grow in bunches, umbel fashion, upon the extremities of each large stalk, very much resembling, at their first appearance, a bunch of red coral; these afterwards open into small five-leaved purple flowers, and are succeeded by nuts, which resemble those of the first species. 4. The manibot, or bitter cassada, has palmated leaves; the lobes lanceolate, very entire, and polished. 5. The janipha, or jatropha, has palmated leaves; the lobes very entire; the intermediate leaves lobed with a sinus on both sides. 6. The elata, with ternate leaves, elliptic, very entire, hoary underneath, and long-petioled. See figures of the last in plate 22, which renders a more particular description unnecessary.

The root of bitter cassada has no fibrous or woody filaments in the heart, and neither boils nor roasts soft. The sweet cassada has all the opposite qualities (which reside in the juice) by heat. Cassada bread, therefore, is made of both the bitter and sweet; thus: the roots are washed and scraped clean, then grated into a tub or trough; after this they are put into a hair bag, and strongly pressed with a view to squeeze out the juice, and the meal or farina is dried in a hot stone laveron over the fire; it is then sifted. It also forms excellent puddings, well to millet. The scrapping—of fresh bitter cassada are successfully applied to ill-disposed ulcers. Cassada roots yield a great quantity of starch, which the Persians, after they have been cooked, give the name of tapioca. According to father La}

the bodies of other living insects, and generally in those of caterpillars. These eggs in a few days hatch, and the young larva, which resemble minute white maggots, nourish themselves with the juices of the unfortunate animal, which however continues to move about and feed till near the time of its change to a chrysalis, when the young brood of ichneumon-larvae creep out by perforating the skin in various places, and each spinning itself up in a small oval silken case, changes into a chrysalis, the whole number forming a globe on the shrivelled body of the caterpillar which had supplied them nourishment; and after a certain period emerge in the state of complete ichneumons.

It was the want of an exact knowledge of the genus ichneumon that proved so considerable an embarrassment to the older entomologists, who having seen a brood of ichneumons proceed from the chrysalis of a butterfly, could not but conclude that the production of insects was either a variable and uncertain operation of nature or a regular continuation of the same species. The observations however of Swammerdam, Malpighi, Roesel, and others, have long since removed the difficulties which formerly obscured the history of the insect tribe. See Plate Nat. Hist. figs. 235, 236, &c. There are no less than 415 species of this insect.

The 8th species is the hoven guaniacum of Aublet, or tree which yields the elastic resin called guaiacum, a valuable article of commerce; for a particular account of which see CAOUTCHOUC. The figure we have given is copied from Aublet's tab. 335, and not from the erroneous plate given in the Acta Parisiana.

The 9th species is JAUNDICE. \textit{See Medicine.}

The 10th species is JAW. \textit{See Anatomy.}

The 11th species is IBERIS, \textit{secalice cresces}, or \textit{candy-tuft}, a genus of the silicous order, in the tribe malvaceae, and is the subject of our figure. It is the most remarkable species of the group. The umbellata, or common candy-tuft, a well-known annual. The amara, or bitter candy-tuft. The spermervires, commonly called tree candy-tuft. The scepter-flowers, with white flowers in umbels at the ends of the branches, appearing at all times of the year.

The 12th species is IBEX, \textit{in zoology. See Capra.}

The 13th species is IBIS. \textit{See Tantalus.}

The 14th species is ICE. \textit{See Water, and Cold.}

The 15th species is ICE-HOUSE, a building contrived to preserve ice for the use of a family in the summer season. It is generally sunk some feet in the ground in a very shady situation, and covered with thatch.

The 16th species is ICELAND-AGATE, a precious stone met with in the islands of Iceland and Ascension, employed by the jewellers as an agate, though too soft for the purpose. It is supposed to be a volcanic product; being solid, black, and of a glossy texture. When held between the eye and the light, it is transparent, and greenish, like the glass bottles which contain much iron. In the islands which produce it, such large pieces are met with that they cannot be equally divided in glasshouses.

The 17th species is ICHNEUMON \textit{fj}, the name of a genus of flies of the hymenoptera order. The generic character is, mouth with jaws, without tongue; antenna with more than thirty joints; abdomen in most species forked; piercing erected, with a cylindrical beak. The animals of this genus provide for the caterpillar a manner highly extraordinary, depositing their eggs in
whose vertices meet in the centre of a sphere, supposed to circumscribe it, and therefore have their height and bases equal; wherefore the solidity of one of those pyramids multiplied by $\frac{\text{the number of bases}}{2}$, taking the linear edge of the isosceles triangle, is equal to $\frac{1}{3} \text{ the base} \times \text{height}$. See Fig. 128.

To form an isosceles triangle, describe upon card paper 20 equilateral triangles; cut it out by the extreme edges, and cut all the other lines half through; then fold up by these edges, and the solid will be formed. The linear edge of the isosceles triangle being $\frac{1}{3}$, the surface will be $5A \sqrt{3} = 8.650 A^2$, and the solidity $\frac{A}{2} \sqrt{\frac{2}{3} - 1} = 2.187 A^3$.

ICOSAN DRI, from genus "twenty," and epithet, "a man or husband," is the name of the 15th class in Linnaeus's sexual method, consisting of plants with hermaphrodite flowers, which are furnished with 20 or more stamens, that are insered. When the inner side of the calyx or petals. See BOTANY.

IDES, iudaeus, in the ancient Roman calendar, were eight days in each month, the first of which fell on the 15th of March, May, July, and October, and on the 13th day of other months. They were reckoned backwards: thus they called the 14th day of March, May, July, and October, and the 15th of the other months, the ides iudaei, or the day before; the next preceding day, they called the tertio iudaeus, and so on, reckoning always backwards, till they came to the nones. This method of reckoning time is still retained in the church of Rome, and in the calendar of the breviary.

IDIOT, is a fool or madman from his nature. By the old common law there is a writ de idote inquirendo, directed to the sheriff, to inquire by a jury whether the party is an idiot or not, and if he be, for the maintenance of the fact, the profits of his lands and the custody of his person belong to the king, according to the stat. 17 Ed. II. c. 9, by which it is enacted, that the king shall have the custody of the legal tools, and the profits of the without waste or destruction, and shall find them necessary of whose fees the said lands shall be hoven. And after the death of such idiot, he shall render it to the right heir, so that such idiots shall not alien, nor their heirs be disbarred. But it seldom happens that a jury finds a man an idiot from his nature, but only on cogitant from some particular time, which has an operation very injurious in point of law; for in this case he comes under the denomination of a lunatic, in which respect the king shall not have the profits of his lands, but is accountable for the same to the lunatic when he comes to his right mind, or otherwise to his executors or administrators. 1 Black. 303.

JEER, or JEER-Rope, in a ship, is a large rope reeved through double or triple block, lashed at the mast-head, and on the yard, in order to hoist. See JEAUM.

JEERUM. See Anatomy.

JELLY, in chemistry. If we press out the juice of ripe blackberries, currants, and many other fruits, and allow it to remain for some time in a state of rest, it partly coagulates into a trensulose soft sub stance, well known by the name of jelly. If we pour off the uncoagulated parts, and wash the coagulum with a small quantity of water, we obtain jelly approaching to a state of purity.

In this state it is nearly colourless, unless tinged by the peculiar colouring matter of the fruit; it has a pleasant taste, and a tre-nous consistency. It is scarcely soluble in cold water, but very soluble in hot water; and when the solution cools, it again coagulates into the form of a jelly. When long boiled, it loses the property of gelatinizing by cooling, and becomes analogous to mucilage. This is the reason that in making currant-jellies, or any other jelly, when the quantity of sugar added is not sufficient to absorb all the watery parts of the fruit, and consequently it is necessary to concentrate the liquid by long boiling, the mixture often loses the property of coagulating, and the jelly, of course, is spoiled.

Jelly combines readily with alkalis. Nitric acid converts it into oxalic acid, without removing the jelly. If it is boiled with water, it is esteemed transparent. When distilled it affords a great deal of pyromonous acid, a small quantity of oil, and scarcely any ammonia.

Jelly exists in all acid fruits, as oranges, lemons, and gooseberries, etc. The juice of these fruits is allowed to gelatinize, and then poured upon a scarce, the acid gradually filters through, and leaves the other; which may be washed with a little cold water, and allowed to dry. Its bestorded, and it coagulates into a hard transparent brittle mass, which possesses most of the properties of gum. Perhaps, then, jelly is merely gum combined with vegetable acid.

JELLY, animal. See Gelatin.

JESUITS, or the society of Jesus, a most famous religious order in the Roman church, founded by Ignatius Loyola, a native of Guipuscoa in Spain, who in the year 1528 assembled ten of his companions at Rome, principally chosen out of the university of Paris, and made a proposal to the pope to form a new order; when, after many deliberations, it was agreed to add to the three ordinary vows of chastity, poverty, and obedience, a fourth, which was to go into all countries whither he should judge convenient; on which, Ignatius was created general of the order; which in a short time spread over all the countries of the world, to which Ignatius sent his companions, while he staid at Rome, whence he governed the whole society. The order was abolished by pope Clement XIV. (Gangandii) in 1773. See Gregory's Church History, vol. ii.

JESUITS'ARK. See CINCHONA, and PHARMACY.

JET. See Coal.

JET D'Eau. See HYDRAULICS.

JETSON, JETSEN, or JETSAM, in law, is used for any thing thrown out of a ship or vessel that is in danger of being a wreck, and which is driven by the waves on shore.

Jews. In England in former times, the Jews and all their goods belonged to the chief lord where they lived. By stat. Ed. I. the Jews, to the number of 15,000, were banished out of England, and never returned till Oliver Cromwell restored them.

Whenever any Jew shall present himself to take the oath of abjuration, in pursuance of the 10 Geo. III. c. 10, the words, upon the true faith of a Christian, shall be omitted out of the said oath in administering it to such person; and the taking the said oath by persons professing the Jewish religion, without the said words, in like manner as Jews are admitted to give evidence in courts of justice, shall be deemed a sufficient taking of it.

IGNATIUS, a genus of the monogeneity order, in the pentandria class of plants. The calyx is five-toothed; the corolla is long; the fruit an unilocular plump, with many seeds. There are two species, the principal of which is the amara, a native of India. The fruit of this tree contains the seeds called St. Ignatius's beans. According to some, it is from this plant that the colon brook root is obtained.

IGNIS FATUUS, a common meteor, chiefly seen in dark nights about meadows, marshes, and other moist place, on bare grounds, and near dung-hills. It is known among the people by the appellations, Will with a wisp, and Jack with a lantern. See Meteors.

IGNORAMUS. See Calorie, and Chemistry.

IGNORAMUS, was formerly indorsed by the grand jury on the back of a bill, for which they did not find sufficient evidence; but now, since the proceedings were in English, they indorse "no bill," or "not a true bill," or which is the better way, "not found." 4 Stob. 305.

IGUANA. See Lacerta.

JIB, the foremost sail of a ship, being a large stay-still extended from the outer end of the bowsprit prolonged by the jib boom, towards the fore-top-mast head. See Sail.

JIB-BOOM, a boom run out from the extremity of the bowsprit, parallel to its length, and serving to extend the bottom of the jib, and the stay of the fore-top-gallant-mast.

JUNIPER, the holm of the British, or the genus of the tetragnata order, in the tetrandria class of plants, and in the natural method ranking under the 430 order, chamois. The calyx is quadriradiated; the corolla rotaceous; there is no style; the berry is monoeious. There are 16 species of this genus; but the most remarkable is the aquifolium, or common holly. Of this there are a great number of varieties with virigated leaves, which are propagated by the nursery gardeners for sale. The best of these varieties are the painted-holly holly, British holly, Bradley's best holly, phyllis or cream holly, milkmaid holly, Fratich's best holly, golden-edged hedgehog holly, Chitty's holly, glory-plated holly, broderick's holly, Partridge's holly, Herefordshire white holly, Blinda's cream holly, Longstaff's holly, Eales's holly, silver-edged hedgehog holly. All these varieties are propagated by budding or grafting them upon stocks of the common green holly.

Sheep in the winter are fed with droppings of holly. Birds eat the berries. The bark is fermented, and afterwards washed to make the common birdlime. The plant makes an impermeable fence, and bears cropping; however, it is not found in.
all respects to answer for this purpose equally well with the hawthorn. The wood is used in fineering, and is sometimes stained black to imitate ebony. Handles for knives, and covers for mill-bellows, are made of it. Miller says, he has seen the floor of a room laid with compartments of holy and mahogany, which had a very pretty effect.

ILLEGIBLE, a genus of the monogy- num order, in the pentadactyla class of plants, and in the natural method ranking under the 12th order, holocarce. The calyx is pentaphyllous, and cartilaginous; there is no corolla; the stamens is simple; the capsule quinqueseptal, and monospermous. There are 21 species, of which the most remarkable are the paronycha and the capitum. Both these have trailing stalks near two feet long, which spread on the ground, furnished with small leaves like those of knott grass. The heads of the flowers come out from the joints of the stalks, having neat silvery bracts surrounding them, which make a pretty appearance. Their flowers appear in June, and there is some succession of them for at least two months; and when the autumn proves warm, they will ripen their seeds in October.

ILICUM, a genus of the pentagynia order, in the escorcia class of plants, and in the natural method ranking with those of which the order is doubtful. The calyx is tetraphyllous, and deciduous; there are eight petals, and eight petaloid subulated nectaritla. There are 16 stamina with bulb anther; the capsules are ovate, compressed, and monospermous. There are two species, viz. 1. The floridum, with red flowers, and very odorous fruit. It is a native of China. 2. The amanum, a native of the woods of China and Japan. The first is a very ornamental plant, and now common in our greenhouses.

ILLUMINATING, a kind of miniature-painting, antiently much practised for illustrating and adornning books. Besides the sweeter books, there were artists whose profession was that of illuminating and paint manuscript, who were called illuminators: the writers of books first finished their part, and the illuminators embellished them with ornamental letters and paintings. We frequently find in manuscripts for the illuminators, which were never filled up. Some of the antique manuscripts are gilt and burnished in a style superior to later times. Their colours were elegant, and their skill in preparing them must have been very great.

IMAM, a name applied by the Mahomet- ans to him who is head of the congregation in their mosques; and by way of eminence to him who has the supreme authority both in respect to spirituals and temporals.

IMBUE, signifies to steel, piller, or par- loin, and also to waste or diminish goods, &c. entrusted to a person's charge and care. Im- belers of wood forfeit double damages, and may be committed to the house of correction till paid; and servants imbibing their mas- ters' goods to the value of 40s. are deemed guilty of felony without benefit of clergy.

IMBRICATED, among botanists, an appellation given to such leaves of plants, as are placed over one another like the tiles of a house. The term is likewise applied to some of the heart-shells, from their being ridged transversely in the same manner.

IMMEMORAL: in a legal sense, a thing is said to be of time immemorial, or time out of mind, that was before the reign of king Edward II.

IMMERSION, in astronomy, is when a star or planet is so near the sun with regard to our observations, that we cannot see it; being enveloped and hid in the rays of that luminary. It also denotes the beginning of an eclipse of the moon, or that moment when the moon begins to be darkened, and to enter into the shadow of the earth; and the same term is also used with regard to an eclipse of the sun, when the disk of the moon begins to cover it. In this sense immersion stands op- posed to immersion, and signifies the moment wherein the moon begins to come out of the shadow of the earth, or the sun begins to show the parts of his disk which were hid be- fore. Immersion is frequently applied to the satellitics of Jupiter, and especially to the first satellite; the observation of which is of so much use for discovering the longitude. The immersion is the instant wherein it appears to enter within the disk of Jupiter, and its duration the moment when it appears to come out. The im- mersions are observed from the time of the conjunction of the moon with the sun, to the time of his opposition; and the eclipses from the time of his opposition to his conjunction.

IMPALED, in heraldry: when the coats of a man and his wife are not on an heiress are borne in the same escutcheon, they must be marshalled in pale; the husband's on the right side, and the wife's on the left: and this the heralds call baron and feue, two coats impalid. See HERALDY.

IMPAIRANCE, in law, a petition in court for a day to consider or advise what answer the defendant shall make to the plain- tiff's action, and is the continuance of the cause till another day, or a longer time given by the court, and the right, after the impairments removed, in case of fines levied, &c.

IMPERATIVE, one of the moods of a verb, used when we would command, entreat, or request.

IMPERATORIA, mastersort, a genus of the dignaia order, in the pentadactyla class of plants, and in the natural method ranking under the 4th order, umbellata. The fruit is roundish, compressed in the middle, gibus, and surrounded with a border; the petals are inexo-emarginated. There is but one species, viz. the ostrichum, a native of the Austrian and Stylijan Alps, and other mountainous parts of Italy. The plant is cultivated in gardens for the sake of its roots, which are used in medicine. The root has a flavour similar to that of angelica, and is esteemed a good sedative. There are in- stances of its having cured theague when the bark had failed. It should be dug up in winter, and a strong infusion made in wine.

IMPERFECT, something that is defec- tive, or that wants some of the properties for which the members of the same kind: thus mosses are called imperfect plants, because almost all the plants of this kind are wanting in them; and for the like reason the appellation imperfect given to the fungi and the marine plants. See Moss, Fungi, and Submarine.
IMPETUS, IMPRESSION, IMPOSTHUME.

At this period, and for a long time after, foreigners were the principal importers of goods in this country; and as it was thought that many of them were desirous of their merchandise here, returned with the value in money to their own country, which was deemed a serious injury, many laws were made against carrying out of the realm any gold or silver, either in coin, plate, or bullion; and merchant strangers were compelled to give security that they would lay out all the money they received for the wares they imported, in English merchandise to be exported. These indulgent restrictions have been the subject of much debate and of many discussions about the prohibition of some foreign manufactures, the import trade of this country is probably as free as the regulations necessary to secure the payment of heavy duties on almost every article of trade will admit.

Total official value of the imports of Great Britain in the year 1800.

Port of London £18,843,172 2 10
The exports 9,514,642 11 10

England - 28,357,814 14 8
Scotland 2,215,790 11 8

East Indies and China. All other parts.
In 1801 £5,424,441 £27,371,115
1802 5,704,606 25,047,412
1803 6,348,387 21,693,777
1804 5,214,621 23,080,869
1805 24,273,431

The official value of the imports of Ireland in the year 1805, was 5,983,194. 15s. 9d.

IMPOSSIBLE roots, in algebra. To discover how many impossible roots are contained in any proposed equation, Sir I. Newton gave this rule, in his Algebra, viz.: Constitute a series of fractions, whose denominators are the series of natural numbers 1, 2, 3, 4, 5, &c. continued to the number showing the index exponent of the highest term of the equations, and then the numerators the same series of numbers in the contrary order; and divide each of these fractions by the next preceding, and place the resulting quotients in the intermediate terms of the equation; then under each of the intermediate terms, if its square multiplied by the fraction over it, be greater than the product of the terms on each side of it, place the sign +; but if not, the sign — , and under the first and last term place the sign +. Then will the equation have as many imaginary roots as there are changes of the underwritten signs from + to — , and from — to +. So for the equation $x^2 - 4x + 4 = 0$, the series of fractions is $\frac{2}{1}$, $\frac{1}{2}$, then the second divided by the first gives $\frac{2}{3}$ or $\frac{1}{3}$, and the third divided by the second gives $\frac{1}{3}$; hence these quotients placed over the intermediate terms, the whole will stand thus:

$$x^2 - ax + a^2 = 0,$$

Now because the square of the second term multiplied by its superscribed fraction, is $\frac{x^2}{a^2} + \frac{a}{x} + \frac{1}{x^2}$, which is greater than $\frac{a}{x}$, the product of the two adjacent terms, therefore the sign + is set below the second term; and because the square of the first term multiplied by its over written fraction, is $\frac{x^2}{a^2} + \frac{a}{x} + \frac{1}{x^2}$, which is less than $24x^2$, the product of the terms on each side of it, therefore the sign — is placed under that term; and the sign — is set under the first and last terms. Hence the two changes of the underwritten signs ++ — , the one from + to — , and the other from — to +, shew that the given equation has two impossible roots.

When two or more terms are wanting together, under the place of the first of the deficient terms write the sign — , under the second the sign +, under the third — , and so on, always varying the signs, except that under the last of the deficient terms must always be set the sign +, when the adjacent terms on both sides of the deficient terms have contrary signs. As in the equation,

$$x + 3x^2 + 5x^3 + 7x^4 = 0,$$

which has four imaginary roots.

The author remarks, that this rule will sometimes fail of discovering all the impossible roots of an equation, for some equations may have more of such roots than can be found by this rule, though this seldom happens.

Mr. Macaulay has given a demonstration of this rule of Newton's, together with one of his own, that will never fail. And the same has also been done by Mr. Campbell.

See Phil. Trans. vols. 24, 25.

The real and imaginary roots of equations may be found from the method of fluxions, applied to the doctrine of maxima and minima; that is, to find such a value of x in an equation, expressing the nature of a curve, made equal to y, as it would correspond to the greatest and least ordinate. But when the equation is above three dimensions, the computation is very laborious. See Stirling's Treatise on the Lines of the Third Order.

IMPOSTHUME, the same with abscess.

See Surgery.

IMPRESSING men. The power of impressing seamen for the sea service, by the king's commission, has been a matter of some dispute, and submitted to with great reluctance, though it has very earnestly been argued by sir Michael Foster, that the practice of impressing, and granting power to the admiral for that purpose, is of very ancient date, and has been continued by a regular series of precedents to the present time, whence it concludes it to be part of the common law. The difficulty arises hence, that no statute has expressly declared this power to be in the crown, though many of them very strongly imply it. The stat. 2 R. II. c. 4. speaks of mariners being arrested and retained for the king's service, as of a thing well known and practised without dispute, and provides a remedy against the running away.

By stat. 2 and 3 P. and M. c. 16, if any waterman who uses the river Thames, shall hide himself during the execution of any commission for pressing for his majesty's service, he is liable to heavy penalties. By the stat. 5 Eliz. c. 6. no fisherman shall be taken by the queen's commission to serve as a mariner; but the commission shall be first brought to two justices of the peace, inhabiting near the sea-coast where the mariners are to be taken, to the intent that the justices may
INCAPACITY, in the canon law, is of two kinds: 1. The want of a dispensation for age in a minor, for legitimation in a bastard, and the like; this renders the provision of a benefice valid in its original. 2. Crimes and heinous offences, which annul provisions at first valid.

INCCH, a well-known measure of length, being the twelfth part of a foot, and equal to three inches in length.

INCIDENCE, in mechanics, denotes the direction in which one body strikes on another. See Mechanics, and Optics.

INCLINATION, is a word frequently used by mathematicians, and signifies the mutual approach, tendency, or leaning, of two lines or two planes towards each other, so as to make an angle.

Inclination of a right line to a plane, is the acute angle which that line makes with another right line drawn in the plane through the point where the inclined line intersects it, and through the point where it is also cut by a perpendicular drawn from any point of the inclined plane.

Inclination of the axis of the earth, is the angle which it makes with the plane of the ecliptic; or the angle contained between the planes of the equator and ecliptic.

Inclination of a planet, is an arc of the circle of inclination comprehended between the ecliptic and the plane of a planet in its orbit. See Astronomy.

The greatest inclination of Saturn, according to the chart of the Charta, is 22°; of Jupiter, 19° 28'; of Mars, 13° 30'; of Venus, 27° 29'; of Mercury, 6° 54'. According to de la Hire, the greatest inclination of Saturn is 23° 30'; of Jupiter, 19° 20'; of Mars, 11° 51'; of Venus, 29° 53'; of Mercury, 6° 53'.

Inclination of a plane, in dialling, is an arch of a vertical circle, perpendicular both to the plane and the horizon, and intercepted between them. To find this, let AB (see Plate Nine, fig. 133) be a plane inclined to the horizontal HR; apply to the plane AB a quadrant DCF, so that the plummet CME may cut off any number of degrees on the limb, as EF: then the arch DE is the measure of the angle of inclination ABH; for draw $BG$ perpendicular to $EF$, then the angle $CBG$ is parallel to $BG$, the angle $EBC$ is equal to $CIG$; but $DCF$ is equal to $GBH$, being both right angles, therefore the angle $DCF = EBC$, is equal to the angle $GBH = CIG$; that is, $DCF = EBC$.

INCLINED PLANE, in mechanics, one that makes an oblique angle with the horizon. See Mechanics.

INCOMMISSURABLE, a term in geometry, used where two lines, when compared to each other, have no common measure, how small soever, that will exactly measure them both. And in general, two quantities are said to be incommissurable, when no third quantity can be found that is an aliquot part of both.

Such are the diagonal and side of a square; for though each of those lines has infinite aliquot parts, as the half, the third, &c. yet not any part of the one, be it ever so little, can possibly measure the other, as is demonstrated by Euclid.

INCOMMISSURABLE NUMBERS, are such as have no common divisor that will divide them both exactly.

INCORRUPTIBLES, or INCORRUPTIBLES, in church history, heretics which had their original at Alexandria, in the time of the emperor Justinian. Their distinguishing tenet was, that the body of Jesus Christ was incorruptible from its conception, by which they meant that after and from the time he was born in the womb of his holy mother, he was not susceptible of any change or alteration even of the smallest kind, and innocent passions, as hunger, thirst, &c. so that he ate without any occasion before his death, as well as after his resurrection.

INCUS, or Night-Shade. See Medicines.

INCUMBENT, a clerk or minister who is resident on his benefice: he is called incumbent, because he does, or at least ought, to bend his whole study to discharge the cure of his church.

INCURVATION, the bending out of a rectilinear or straight course, occasioned by refraction.

INDEMNITY, in law, the saving harmless; or, a retiring to secure one from all damage and danger that may ensue from any act. An indemnity in regard to estates is called a warranty.

INDETERMINED, in heraldry, is when the outline of an ordinary is notched like the teeth of a saw.

INDETERMINED LINE, in fortification, the same with what the French engineers call redent, being a trench and parapet running out and in, like the teeth of a saw, and much used in irregular fortifications.

INDETERMINATION, is a writing containing a conveyance between two or more, indented or cut unevenly, or in and out, on the top or side, answerable to another writing that, in length, comprises the same words. Formerly when deeds were more concise than at present, it was usual to write both parts on the same piece of parchment, with some words or letters written between them, through which the parchment was cut, either in a straight or indented line, in such a manner as to leave half the word on one part, and half on the other: and this custom is still preserved in making out the indentures of a fine. But at last, indented only has come into use without cutting through any letters at all; and it seems at present to serve for little other purpose than to give name to the species of the deed. 3 Black. 294.

INDEPENDENCE of the protestants in England and Holland, so called from their independency on other churches, and their maintaining that each church or congregation has sufficient power to act and perform every thing relating to the church-government within itself, and is no way subject or accountable to other churches or their deputies.

The present independents differ from the presbyterians only in their church government, in being generally more attached to the doctrines distinguished by the term orthodox, such as original sin, election, reprobation, &c. and in administering the Lord's supper at the close of the afternoons service. The several sects of baptists are all independent with respect to church-government; and, like them, administer the Lord's supper in the evening, whereas the presbyterians administer it after the forenoon's service.

INDETERMINATE PROBLEM, in algebra, one which is capable of an indefinite number of solutions.

INDEX, in arithmetic and algebra, shews to what power any quantity is involved, and is otherwise called an index.

Index of a logarithm, that which shews of how many places the absolute number be-
I am unable to provide the natural text representation of this document as the content is not fully visible or legible in the provided image.
There are 35 species, the most remarkable of which is the \textit{tectoria}, a native of the warm parts of Africa, Asia, and America. This plant requires a rich soil, well filled, and not too dry. The seed of it, which, as to figure and colour, resembles gumpowder, is sown in little furrows that are about the breadth of the hoe, two or three inches deep, at a foot distance from each other, and in as straight a line as possible. Continued attention is required to pluck up the weeds, which would soon choke the plant. Though it may be sown in all seasons, the spring is commonly preferred. Moisture causes this plant to shoot above the surface in three or four days. It is ripe at the end of two months. When it begins to flower, it is cut with pruning-knives; and cut again at the end of every six weeks, if the weather is a little rainy. It lasts about two years, after which term it degenerates: it is then plucked up, and planted afresh. As this plant soon exhausts the soil, but also does not absorb a sufficient quantity of air and dew to moisten the earth, it is of advantage to the planter to have a vast space which may remain covered with trees, till it becomes necessary to fell them in order to procure the indigo.

The valuable dye-stuff called indigo bears some resemblance to starch; but its properties are sufficiently peculiar to distinguish it from all other substances, and its importance entitles it to a distinguished place among vegetable principles. It is commonly procured by the following process:

When the plant has been cut down, it is placed in strata in a large wooden vessel, and covered with sure. In this situation it cannot remain long in these warm climates without undergoing some change. Putrefaction, accordingly, very soon commences, or rather a kind of fermentation, which goes on best at the temperature of 80°. The water soon becomes opaque, and assumes a green colour; a smell resembling that of volatile alkali is exhaled, and bubbles of carbonic acid are emitted. When the fermentation has continued long enough, which is judged of by the paleness of the leaves, and which requires from six to twenty-four hours according to the temperature of the air and the state of the plant, the liquid is decanted from the plant, and the water is then carried away to an evaporation place, where it is constantly agitated till blue floculi begin to make their appearance; water is now poured in, which causes the blue flakes to precipitate. The yellow liquid is decanted off, and the blue sediment poured into linen bags. When the water has drained from it sufficiently, it is formed into small lumps, and dried in the shade. In that state it is imported into Europe, and sold under the name of indigo.

The leaves of the indigofera yield a green infusion to hot water, and a green powder may be precipitated from it; but unless a fermentation has taken place, neither the colour nor properties of it have any resemblance to indigo.

Indigo may be obtained from the mercuric tincturium, and the \textit{indigofera} or \textit{wool}; a plant commonly enough cultivated in Britain, and even found wild in England. When this plant is cut down, and arrives at maturity, this plant is cut down, weighed, dried hastily in the sun, ground in a mill, placed in heaps, and allowed to ferment for a fortnight. It is then well mixed, and made up into balls, which are piled upon each other, and exposed to the wind and sun. In this state they become hot, and exhale a putrid ammonical smell. The fermentation is promoted, if necessary, by sprinkling the balls with water. When it has continued for some time, a sufficient thick smut of powder is allowed to form on a coarse powder, in which state it is sold as a dye-stuff. By treating wood nearly in the same manner with the indigofera, indigo has been obtained from it by different chemists.

Indigo is a fine light friable substance, of a deep-blue colour. Its texture is very compact, and the shade of its surface varies according to the manner in which it has been prepared. The principal tints are copper, violet, and blue; the lightest indigo is the best: but it is always more or less mixed with foreign substances, partly owing, doubtless, to the carefulness of the preparation, and partly to the bodies which the plant containing indigo yields to water. From the analyses of Bergman, to whom we are indebted for one of the most complete treatises on the properties of indigo which has yet appeared, the purest indigo, in which he could procure, was composed of the following constituents:

\begin{itemize}
  \item 47 pure indigo
  \item 12 gun
  \item 6 resin
  \item 22 earth
  \item 13 oxide of iron
\end{itemize}

The earth consisted of:

\begin{itemize}
  \item 10.2 barites
  \item 10.0 lime
  \item 1.8 silica
\end{itemize}

The indigo is almost the same as that of the \textit{ilicis}.

But in all probability the earth differs in different specimens; for Proust found magnesia in considerable quantity in the specimens which he examined. The forty-seven parts of bluish pigments are alone entitled to be called indigo; and to them therefore we shall confine our attention.

Indigo is a soft powder, of a deep blue, without either taste or smell. It undergoes no change, though kept exposed to the air. Water does not dissolve any part of it, nor produce any change upon it. Bergman, however, found that indigo, when kept long under water, underwent a kind of putrefaction, or at least exhibited a fetic colour. When a heat is applied to indigo, it emits a bluish red smoke, and at last burns away with a very faint white flame, leaving behind it the earthy parts in the state of ashes.

Neither oxides, or the simple combustibles, have any effect upon indigo, except it is in a state of solution; and the same emblem applies to the metallic bodies.

The fixed alkaline solutions have no action on indigo, except it is newly precipitated from a state of solution. In that case they dissolve it with facility. The solution has at first a green colour, which gradually disappears, and the natural colour of the indigo comes again upon it, so that we see with reason to doubt that the alkalies when concentrated decompose indigo. Pure liquid ammonia acts in the same way. Even carbonates of ammonia dissolves precipitated indigo, and destroys its colour; but the fixed alkaline carbonates have no such effect.

Lime-water has scarcely any effect upon indigo in its usual state; but it readily dissolves precipitated indigo. The solution is at first green, but becomes yellow.

When the solution is exposed to the air, a slight green colour returns, as happens to the solution of indigo in ammonia; but it soon disappears. The effect of the other alkaline earths upon indigo has not hitherto been tried; but it cannot be doubted that they would act nearly as lime-water, but with more energy. The other earths seem to have but little action on indigo in any state.

The action of some on indigo has been examined with most attention, and it certainly exhibits the most important phenomena.

When diluted sulphuric acid is digested over indigo, it produces no effect, except that of dissolving the impurities; but concentrated sulphuric acid dissolves it readily.

One part of indigo, when mixed with eight parts of sulphuric acid, evolves heat, and is dissolved in about 24 hours. According to Hauy, some sulphuric acid and hydrogen gas are evolved during the solution.

If so, we are to ascribe to the mucilage and resin, which are doubtless destroyed by the action of the concentrated acid. The solution of indigo is well known in this country by the name of liquid blue. Bancroft calls it sulphat of indigo. When concentrated it is opaque and black; but when diluted it assumes a fine deep blue colour; and its intensity is such, that a single drop of the concentrated sulphat is sufficient to give a blue colour to many pounds of water. Bergman ascertained the effect of different reagents on this solution in great precision. His experiments threw light, not only on the properties of indigo, but upon the phenomena that take place when it is used as a dye-stuff. The following is the sum of these experiments:

Drop into sulphuric acid. Colour at first blue, then green, and very speedily destroyed. — In weak tartaric acid. Becomes gradually green, and in 144 hours had assumed a very pale blue, not restored by the alkalis. — Colour becomes green, and in four weeks the colour disappeared. — In weak potash. Becomes green, and then colourless. — In weak carbonat of potash. These actions, however, are not very slow. If the solution is very weak, the colour of the indigo is not destroyed. — In ammonia and its carbonat. Colour becomes green, and then disappears. — In a weak solution of sulphat of soda. Colour after some weeks becomes green. — In tartrat of potass. Becomes green, and then colourless. — In a solution of sugar. Became green, and at last yellowish. — In sulphat of iron. Colour became green, and in three weeks disappeared. — In the sulphates. Colour destroyed in a few hours. — Realgar, white oxide of arsenic, and orpiment, produced no change. — Black oxide of manganese destroyed the colour completely. — In the infusion of madder. Indigo became green, and at last yellow. — In the infusion of woad, the same changes, but more speedily.

From these experiments it is obvious that all those substances which have a very strong affinity for oxygen give a green colour to indigo, and at last destroy it. It is hence extremely probable that indigo becomes green...
by giving out oxygen. Of course it owes its blue colour to that principle. This theory was first suggested by Mr. Haussman, and still further confirmed by Berthollet. Now it is only when green that it is in a state capable of being held in solution by lime, alkalis, &c. in which state it is applied as a dye to cloth. The cloth when dip-dyed into the vat containing it, thus dissolved, combines with it, and the blue colour is restored by exposure to the atmosphere. It may be restored equally by plunging the cloth into ozo-muriatic acid. Hence the restoration cannot but be ascribed to oxygen. Hence, then, the reason that sulphurous acid, the vegetable acids, sulphat of iron, give sulphat of indigo a green colour.

From these experiments we see also that the colour of indigo is destroyed by the addition of those oxides which part with oxygen very readily, as the black oxide of manganese. In that case the indigo is destroyed, for its colour cannot be again restored. Nitric acid attacks indigo with great violence, the evolution of much heat, and nitric gas. When of the specific gravity 1.32, it even sets fire to indigo. When the acid is diluted the indigo becomes brown, and crystals make their appearance, doubtless consisting of oxalic acid. What remains behind is a brown viscous substance of a very bitter taste, probably analogous to the yellow bitter principle of Welter.

Muriatic acid does not act upon indigo in its constant state, but it readily dissolves indigo precipitated from the sulphat, and forms a blue coloured solution. The same phenomena are exhibited by the phosphoric, acetic, tartaric acids, and practically by all, except the oxalic acid supporters.

Oxy-muriatic acid destroys the colour of indigo as readily as nitric acid, and obviously for the same reason.

Indigo is not attacked upon by alcohol, ether, nor oils. The two first solvents, indeed, acquire a yellow colour when digested on common indigo by dissolving its resin.

When indigo is mixed up with bran, wood, and other similar substances, and subjected to undergo fermentation, it assumes a green colour during the fermentation, and is then easily dissolved by lime or potash. It is by this process that it is usually rendered proper for dyeing purposes.

When indigo is distilled, it yields products different from any other vegetable substance, if the accuracy of Bergman, who alone has made the experiment, is to be trusted. He distilled 576 grains in a small retort under a pressure of a pneumatic apparatus. He obtained the following products:

- 19 grains carbonic acid gas 173 - of a yellow acid liquid, containing ammonia
- 53 - oil
- 331 - charcoal
- 476.

INDIVISIBLES, in geometry, the elements or principles into which any body or figure may be ultimately resolved; which elements are supposed infinitely small: thus a line may be divided to consist of points, a surface of parallel lines, and a solid of parallel and similar surfaces; and then, because each of these elements is supposed indivisible, if in any figure a line be drawn through the elements perpendicularly, the number of points in that line will be the same as the number of the elements; so that a parallelogram, prism, or cylinder, is resolvable into elements or indivisibles, all equal to each other, parallel and like to the base; a triangle into lines parallel to the base, but descending on the lines proportional for and so are the circles which constitute the parabolic conoid, and those which constitute the plane of a circle, or surface of an isosceles cone.

A cylinder may be resolved into cylindrical curved surfaces, having all the same height, and continually decreasing inwards, as the circles of the base do on which they insist.

The method of indivisibles is only the ancient method of exhaustion, a little disguised and contracted. It is founded of great use in shortening mathematical demonstrations, of which take the following instance in the famous proposition of Archimedes, viz. that a sphere is two-thirds of a cylinder circumscribing it.

Suppose a cylinder, a hemisphere, and an inverted cone (Plate Miscel. fig. 133) to have the same base and altitude, and to be cut by infinite planes all parallel to the base, of which dy is one. It is plain the square of dy will be equal to the area of the base (the radius of the sphere); and consequently, since circles are to one another as the squares of the radii, all the circles of the hemisphere will be equal to all those of the cylinder, deducting the space of those of the cone; before the cylinder, deducting the cone, is equal to the hemisphere; but it is known that the cone is one-third of the cylinder, and consequently the sphere must be two-thirds of it.

INDORSEMENT, in law, any thing written on the back of a deed, as a receipt for money received. See BILLS OF EXCHANGE.

INDORSEMENT, in law, what is alleged as a motive or incitement to a thing, and is used specially in many cases; as, there is an inducement in actions, to a traverse in pleading, a fact or a declaration committed, &c.

Inducements to actions need not have so much certainty as in other cases: a general inducement or burden is not sufficient where it is the ground of the action; but where it is the inducement to the action, in consideration of forbearing a debt till such a day (for that the parties are agreed upon the debt), this being but a collateral promise, is good without shewing how due. 2 Haw. 143.

In any inducement to a satisfaction when what is alleged against it is not the substance of the plea. 4 Bla. 18.

INDUCTION, in law, is the giving a clerk instituted to a benefice the actual possession of the temporalities thereof, in the nature of livery of a pension. It is performed by a mandate from the bishop to the archdeacon, who commonly issues out a precept to some other clergyman to perform it for them; which, being done, the clergyman who induces him indorses a certificate of his induction on the archdeacon's mandate, and they who were present testify the same under their hands, and by this the person induced is in full and complete possession of all the temporalities of his church.

the formation of the nipples. Behold the economy of the infant himself; see him instinctively taught to search for the breast, and to suck the breast; to draw his nourishment from a new source, yet still from your body, and to learn, by degrees, to form a connection sufficiently, you would neither give him over to the sucking of another woman, nor would you feed him with any other substance than your own milk." Dr. Herdan on Feeding.

Dr. Buchan gives it as his opinion, that not one in a hundred of those children survives who are abandoned by their mothers, and committed to the charge of foster-parents in the earliest stages of life; and although we may deem this statement in some measure exaggerated, the reflection of its approach to truth ought to be a sufficient incentive for the appointed and professed guardians of the health and we-being of society to enter a severe and unrestrained protest against the custom to which we now refer.

For the first two or three months the nourishment of the infant ought to be received entirely from the breast of its mother. During the whole of this time its wants are almost confined to nourishment and sleep. It is, however, generally confessed that there are some, although comparatively few, instances of imbecility on the part of the parent to furnish milk in due quantity or suitable quality to the necessities of her offspring. "To the puffy progency of a pumy consumptively disposed mother I would forbid (says Dr. Beddoes) the mother's breast." Now, although we are inclined to suppose that the author just quoted has admitted too much in favour of what is termed rearing by hand (for capacity of bearing is commonly connected with a capacity of nursing children), yet, where circumstances necessarily deprive the child of its regular and more salutary nourishment, it becomes a question of moment, what is to be substituted in its place? Not by any means what the generality of hired attendants direct. As soon as an infant by its cries denotes hunger, the nurse has, for the most part, instant resort to a mixture of bread and water (pap), which is perhaps spiced, or qualified with a little brandy. To attempt the union of oil and water would be scarcely less incongruous; it is not hazarding any thing to assert, that the major part of infanticile ailments are to be attributed to the heterogeneous compounds that are early given to children; and the spicy or spirituous ingredients which are added, in order to force an artificial digestion, the necessity of the latter bears decided evidence against the propriety of the former. In no period of life, during health, ought food to be of such a quality as to require the assistance of condiments or spices, which are especially injurious to the assimilating organ of a newly-born infant.

About half a tea-cupful of cow's milk, gently warmed, is the only food that ought to be given to a child at its birth, after which it will frequently stand alone, and indeed often alarming to the intrusive agitation of nurses, is to be regarded as a demonstration of the proper nature of the food that has been given, and an indication of future health. To this plan it is sometimes necessary to have recourse, even when it is the intention of the mother to suckle her child, as women who have had many children frequently have no proper secretion of milk until after the second or third day from delivery.

Before quitting this part of the subject it is proper to observe, that immediately after the purgatives, as if to prove to the little stranger that it has arrived in a world of physic and of evils, is, although very generally adopted, highly injurious. The bowels do not, in general, require to be thus artificially assisted.

With respect to the quantity and times of administering food, mothers and nurses are accustomed to err. Nothing can be more improper than to suck or feed an infant two or three times in the course of an hour. A child judiciously regulated does not demand nourishment, even during the first months, more than once in three or four hours; as it advances it requires feeding even less frequently, and less deep during the day.

It has already been stated, that, with the exception of suckling, the mother's breast, at least during the first two or three months, is to be the sole repository and entire source of infantile nourishment. If the child is brought up by hand, cow's milk generally warms in the food that will be necessary for the first four or five months. After these times milk may be alternated, not by most bread, biscuit, cakes, sugar, bananas, and gui, but by ground rice or flour well baked; the gravy of spiced meat, which last will generally be taken with avidity; small quantities of beet-root, or veal-jelly, and other substances of the like nature; still avoiding, unless during the actual existence of disease, and under professional direction, every article in the long list of fermented, fermenting, spiced, and spirituous materials; the withholding of which, however it may offend and alarm the nurse, will be of incalculable benefit to the child.

The time of weaning must be regulated entirely by circumstances. The process should not be abrupt, but gradual. It is very seldom that the breast is rejected before the ninth or tenth month.

We have particularly insisted on the necessity of excluding those substances from the diet of infants which are disposed to ferment or turn sour. A general acquaintance with the laws which regulate the existance and decomposition of such substances may be acquired with less labour than would be requisite to retain in the memory, without the aid of some connecting principle, all the individual facts which are prescribed or admitted as part of the diet in childhood and youth; and in consequence of such pleasing and easy acquisition, we should gain knowledge and humanity joining true in the joyous task of averting that ignorance and error have made to attack the extremely susceptible, though not naturally unhealthy, state of the primary periods of existence. Whence does the perversity of nurses and of children arise? Solely from ignorance. Were they convinced that the plans which are adopted prove ultimately subservient of their intended object, they would readily adopt a system of treatment of children: Obedience will always be more cheerful and steady after a reasonable explanation. "I have heard a variety of mothers (says Dr. Beddoes) complain that sugar, biscuit, and cakes, disagreed in the most evident manner; and yet that it was impossible, by any injunctions, to prevent the child from being given the food, and the other (sugar) from being given to stem the hiccups, or to produce a sensation that should suspend crying for a moment. Now it is well known that punctually recurring constrictions in the stomach and bowels arise from those sources; and the parties, by whose mistake, the effect of which is so pernicious, are perfectly informed of it. It remains only to carry their knowledge a step farther. Respecting the juice of the sugar-cane, it is a very striking particular, that the poorest sort will scarcely keep a quarter of an hour in the receiver without turning sour. This can only be told. The acceint nature of bread, of sugar, and of the various compositions into which bread and sugar enter, may be shewn. For this purpose it is only necessary that a solution of sugar and water should be made into vinegar. Viz., that the sugar and water solution can be placed in a bottle nearly equal to that of the human body, and the servant be put to taste the infusion when it becomes acid. By an address suited to the object in view, there will only be small difficulty in giving these simple experiments all the effect that can be desired."

"I shall very contentedly allow the childless and wretched to laugh at me for the whimsical idea of introducing sugar into this country. I have a baulk at hand for any wound the shafts of ridicule may inflict. Considerate parents will avail themselves of so practicable an expedient, and many little sufferers will escape the consequence of an improper regimen. And these are probably (the author might have said certainly) far more serious, even in respect to the future than the present. For it clearly results from a contemplation of the manner in which human feelings and interests gain their connection, that frequent discomposure of the stomach in the morning of life may be instrumental in overcaressing its meridian and its close with a cloud of misery, such as the smallest skin trouble can dispense." Dr. Beddoes' Hygiene. For further information on the subject of diet, consult the article Materia Medica, section Dietetics.

Sect. II. Of temperature, including remarks on the clothing, and likewise on the washing or bathing of infants.

The remarkable success with which the subject of animal temperature has been recently investigated, and the application of facts, deduced from a development of its laws, to the living system, both in its healthy and diseased state, constitute perhaps the most material improvements in modern physiology and medical practice.

Respecting the generation and adjustment of animal heat, it is not the business of this article to enquire (see PHYSIOLOGY, and MEDICINE); our present plan extends no farther than the statement of a few practical rules on the subject of heat and cold, absolutely necessary to be attended to by all who undertake the guardianship of infancy and childhood: «"the management of temperature is of high importance in the treatment of the infant. It runs through, and is connected with, every part of his general treatment.»
INFANCY.

To be considered in his dress, in his covering while asleep, in his bathing or washing, in his treatment in the house as well as out of it, in his air and exercises. With a considerable knowledge of the management of temper-ature, a nurse can scarcely go wrong in any part of the general treatment of an infant. Herdman.

It must be obvious to every one that the infant at birth necessarily undergoes a sudden and material alteration in the temperature of the medium by which, without clothing, it is surrounded. The effects which would result otherwise from this remarkable change, with respect to external warmth, are in some measure obviated by the immediate commencement of respiration. This, however, is not sufficient of itself to supply the defect of external heat. The change thus must be artificially rendered as gradual and imperceptible as possible; and the infant, during the first month, ought scarcely to be exposed to any sensible degree of cold, even for the shortest period. It has been with much difficulty that I have been able to practice to direct that the new-born child be immediately washed with cold water, and other irritating substances, in order to cleanse the surface of the body previously to its being covered with the garments. This custom, however, by our forefathers, or even proper, is the use of warm water and sponge, without any further friction, after washing, than what is necessary completely to dry the skin; indeed the propriety of washing, as many moderns direct, that of an infant at birth, has lately been denied by an author whom we have already quoted; but we think that the use of tepid water, applied with gentleness, and without any subsequent violence of friction, can in no case be objectionable, but ought always to be had recourse to.

As soon as this process is completed, the infant is to be immediately clad; and at this period let the habits of the common routine of nurses and of friends be as sedulously watched, and as earnestly opposed, as in relation to its diet. If the customary mode of feeding infants has induced a long train of pernicious and pernicious habits in drinking, and (which, till very late years, has been persisted in with all the cruel pertinacity of continuance (ignorance), there has been also productive of fatal results, this manner of feeding, that is, the raising the temper of the air, occasioned by an unsuspected breach in the window, directed on the body of a sleeping infant, has often been productive of serious injury. Dr. Bodloe directs that the door of the nursery be never opened to fall below fifty degrees; and it is always to be carefully retained in the memory, that the deficiencies occasioned by ill-constructed buildings can never be compensated by heating the air of the fire; "if the nursery is not only the air rendered impure, but the temperature of the room is made still more irregular, and the danger of colds consequently increased."

There is one caution which is especially necessary with regard to the temperature and economy of nurseries. All occasions and sources of damp must most assiduously be guarded against. This caution is the more necessary, because the danger from this source appears to be the least understood or suspected. It is not uncommon to observe that parents and nurses who would dread the opening of a sash-window, at the same time unwarily expose themselves and the children to a much greater degree of cold by permitting the suspension of wet clothes, in order to dry, about different parts of the apartment, and even by careless respect of the window-frame. The process of drying is the process of producing cold, and that too of the most noxious kind; for cold, when combined with moisture, has been proved, in an excessive degree, injurious to the animal economy. Damp is equally insidious. We are thus inclined to believe that from this cause originate many scorbutic and other infantile ailments so peculiarly prevalent in the British isles; and that where the diseases have been favourably attributed to debilities and premises in the water we drink, and various other sources. By every individual, but more especially by the parents and guardians of infancy and youth, freedom from damp should be the first and great requisite in the choice of apartments and houses.

But to return to the infant’s dress. The covering which we have recommended ought to be continued for the first six or seven weeks of infancy; during this period, as we have already observed, nourishment, warmth, and repose, are almost its only requisites. After this time, however, or towards the close of the second month, the infant economy begins to change; vital action commences now to be connected with voluntary muscular motion; the perceptive faculty is gradually developed; and the whole organization appears to undergo a change. The body is now warmed in a greater degree and more easily by actions of its own production, and heat of its own formation. Externally, the nursery is daily less necessary; and that quantity and kind of clothing which before were proper and needful, now become irksome and tormenting. With this progress of growth the summer months are at the same time about to appear, the covering of the child may, in a short time, be reduced even to a shirt and single external garment; the utility of this light clothing will be rendered evident by the feelings and expressions of the infant. It is almost unnecessary to observe, that general precepts are incapable of undeviating and indiscriminate application. The changes of the weather, the season of the year, and the delicacy or robustness of the constitution, will interfere with every rule, and give exercise to the independent judgment of every parent. Providence has, however, by its own law, in that, in this, as in every other respect, the dictates of nature, which are communicated by the desire and aversion of the infant, furnish the most faithful directories with respect to its management; the utility of this light clothing will be perceived with such distinctness and precision as to be generally intelligible. It is only by disobeying nature’s laws that, in the treatment of infancy, we have wandered wide of the path of rectitude, and are under the necessity of retraceing our steps.

We now close the present section by a few additional remarks on the much-contested question of bathing. It has already been observed, that an exposure upon any entrance into the world, should be immediately washed with tepid or warm water. Others recommend immersion rather than ablution. "For a new-born infant (says Dr. Bodloe) I should prefer instant immersion in water at eighty degrees to washing. It is perhaps immaterial to which mode of cleansing we have recourse, unless the latter may be deemed objectionable on account of the unnecessary check it may make upon the respiratory frame. It is likewise to be observed, that conveniences for the former are procured with more facility than the latter; and that it is not every nursery that can, without difficulty, be furnished with a proper vessel for
INFANCY.

If the practice of immersion is guided by a cautious observance of these particulars, it may be said to be attended with success; but a total neglect of bathing would be greatly preferable to the severe and incalculable manner in which infants are frequently exposed to these violent and rapid changes in temperature. It ought to be added, that whether washing or immersion is employed, much care should be taken in drying the skin, particularly in those parts in which it is loosely situated, as about the groin, and in the epitrochlear region. As the extremities are much less susceptible of injury than other parts of the body, with the aliment that is taken into the stomach: regards the grounds of this opinion it would not be in place, in the present article, to institute any enquiry. (See Mr. Wilkins, M.R.C.S., Epist. Section Dietetics.) We have here only to impress the necessity of a constant and unremitting regard to ventilation, in order to ensure a healthful condition in the infantile economy.

Both the truth and importance of this principle would seem too obvious even to require notice by a writer on regimens, had he not daily opportunities of witnessing the mischiefs arising from neglecting its application. The public mind, however, appears to be at length awakening from a long lethargy of prejudice and error. We at length begin to breathe and to live. Even among the poorer and lowest classes of the community, cleanliness and ventilation come to be acknowledged as the surest barriers against the invasion of disease. Although, however, on this subject modern science has much to boast, much is still to be accomplished, and even in the present day examples cannot be too frequently pressed upon public observation of the injurious tendency, especially in the susceptible and delicate period of infancy, of neglected ventilation. There is reason to suppose that, from the imputation of our ancestors to fresh air, multitudes must have perished in the very dawning of existence. In our times grown persons have been dangerously affected by such a deficiency of this necessary of life, as did not even produce immediate uneasiness. Infants have perished in great numbers by a slow suffocation, terminating in convulsions. As soon as the want of ventilation was observed the mortality has ceased. Beddoes. A fact, of which the following relation furnishes irrefragable evidence. In the lying-in hospital at Dublin 2,944 infants, out of 7,530, died in the year 1782, while the total number born was 7,782. The proportion of infants perished at birth: they almost all expired in convulsions; many fainted at the mouth, their thumbs were drawn into the palms of their hands, their jaws were locked, their faces swollen, and they presented, in a greater or inferior degree, every appearance of suffocation. Such was the weight and frequency of this inquiry whether the rooms were not too close, and insufficiently ventilated. The apartments of the hospital were rendered more airy; and the consequence has been, that the proportion of deaths, according to the register of the succeeding years, is diminished from three to one.

Such facts as these cannot be too often made to pass under review. By the parent anxious for the weal of her offspring, they ought constantly to be enforced upon the minds of servants and nurses, whose sensitiveness in respect to proper ventilation is often only to be equalled by their mismanagement in other particulars. This indifference is often by servants carried to such an extent as very materially to injure their own health. In a large family (says Dr. Darwin) many female servants slept in one room, which they had contrived to render inaccessible to every blast of air. I saw four who were thus seized with convulsions. They were removed into more airy apartments, but were some weeks before they all regained their health. It is very unfortunate that the nostril has been too frequently confined in the same tainted atmosphere; convictions in these would have been much more readily induced, and might perhaps have proved fatal! A child then ought never, in any case, to be permitted to sleep with many individuals in the same apartment. It should not be lulled to rest in its nurse’s arms. When put to sleep in the couch or cradle the face must not be covered; the air must be entirely changed; after the first or second month it should be daily taken out in the open air, when the weather is not cold or damp; this is best done in the forenoon, immediately upon being washed and dressed; care being taken that the infant is not carried too much in one position, and that it does not suffer from cold. Every impediment to the purity of the air within doors is to be as speedily as possible removed. If the skin is prematurely hot, or the little patient becomes restless and febrile, the fires of the nursery are to be extinguished, the windows thrown open, or the apartments changed. It is the misfortune of the atmosphere the free use of the limbs must likewise be added. On exercise scarcely anything remains to be said. Freedom from all constraint is implied in the mode of dress above recommended. To those, however, who imagine that nature can be assisted by the contrivances of art, or that symmetry of form is to be secured by unnatural restriction, it may not be improper to observe, that deformities are only known in those countries where mechanical dexterity has been called upon to prevent them. The infants of the Caiffes (says the author of Travels into the interior of Southern Africa), soon after birth, are suffered to crawl about perfectly naked; and at six or seven months they are able to run. A cripple or deformed person is never seen. In Egypt, again, the hammam is the cradle or school of infancy. From when the infant is born there is nothing covered but the head, and it is dressed with a swathe, the source of a thousand diseases. Laid naked on a mat, exposed in a vast chamber to the pure air, he breathes freely, and with his delicate
PART II.

DISEASES OF INFANCY.

Sec. I.—Mesenteric atrophy (Tubes mesentericae, Alportia infantilis).

This is, in a great measure, the origin and root of the major part of infantile diseases. An affection of the mesenteric glands in children is often connected with, is not unusually the occasion of, and is still more frequently mistaken for, worms; it is the nucleus, through which rickets are produced; it is, in general, the more immediate cause of diarrhoea, and other bowel complaints; and in several instances has been the 'fourth, not the cause, of hydrocele, or dropsy in the brain.'

Than this no complaint bears more evident characters. The physician who has been accustomed to the general aspect of infancy, and its organic disorders, will readily recognize these by the expression of the abdomen. It he perceives a fleshy and tenesmus about the navel, and a general prostration and hardness about the belly, an enfeebled appearance with a laxity, indicating glanular tumefaction; and if, combined with this symptom, a tendency to atrophy, or, as it is called, falling away in flesh and strength, is observed; a greater or lesser degree of mesenteric consumption is present. Such then are the never-failing attendants of the disorder now under notice; they are its distinct and prominent features. A variety, however, of other accessory symptoms, for the most part, display themselves, and constitute part of the malady. Sometimes an universal languor and listlessness will be connected with aecipe to food; at others an insomniac appetite is present. The child is often very precocious; sometimes others the contrary; the evacuations are discoloured, and unhealthy in their appearance; they are, for the most part, slimy, or viscid in their consistence, but are discharged, both in quantity and quality, without the utmost irregularity: the countenance is pale, "except when the hectic flush prints its deceitful and ill-omened animation on the cheek;" the features are, for the most part, full, and languid; the eye is dull; the breathing is oppressed, and spasmodic: the pulse is invariably feebly, but is sometimes slow, and at others inordinately accelerated. In the advanced stages swellings of the feet and ankles are sometimes observed. The little sufferer generally means piteously; and this, if the disorder has arrived to any considerable extent, is almost the only sign which is given of consciousness or feeling.

Causes.—Mesenteric atrophy is most prevalent among the children of the poor, especially in large cities, and in dirty confined situations. "The noxious powers producing it, in the language of Dr. Baunoya, are "notorious."—(Newat's Leechbook, i. p. 274.)" They are the same with those of every other asthma. They are want of food, or diet of watery matter and bread; cold and moisture, the latter increasing the effects of the former; too little nursing (gestations just minus); bad treatment in the times of sleep, meals, and every other part of infantile management; thirst; impure air; an intimation to the instincts of nature in the treatment of children." Elements of Medicine.

To these causes Dr. Brown ought to have added the practice of giving children fermented or spirituous liquors, and those other artificial stimulants, to which we have referred in the former part of the present essay. This custom is extremely prevalent in the inferior classes of society; and hence, in part, the frequency of mesenteric atrophy among the offspring of the poor.

Immediate cause of, and constitutions most obnoxious to, mesentericconsumptions.—The unusual bulk of the abdomen, which is so characteristic of this disease, obviously depends upon a deranged state of the mesenteric glands. The tumefaction, however, does not arise from the source in which it is usually referred to, but is "caused by the presence of tough, rosy tumours, causing an obstruction in the tumefied parts." The theory of mechanical obstruction is indeed totally founded in error, consistent with the theory of the animal economy. It is incompatible with living action; and, as we shall immediately have occasion to observe, has been the cause of much and serious mischief, both in the dog and cat even the parturition, of this and other ailments. "The idea of alternating humours, purifying blood, and clearing passages, rests upon a wrong principle." So far indeed from the glands of the mesentery being less prone to disease than when in a state of health, the exact contrary is the fact; and not only is their area enlarged, but new vessels are often at the same time formed; and hence the morbid increase of bulk.

The attendant atrophy is easy of explanation. The deranged action of the glands in question interferes with the due preparation of the chyle, the whole of which has to undergo the same process as blood. The chyle is the fluid from which the blood is formed; on the quantity and quality of the blood depends health, growth, and life; by its deficiency, or want of due proportion in its component principal parts, mortality, disease, and atrophy, are produced.

The attendant symptoms are not difficult to account for; the torpid and irregular state of the bowels is partly owing to the general inactivity in the lymphatics of the liver; hence the thinner portions of the bile remain unabsobered, and this fluid is in consequence too dulled to afford a due excitation to the intestinal fibre. The slimness and viscosity of the feces arise from the altered condition of the glands of the intestines; and the edematous swellings of the feet are evidences of a general inactivity, or deficient excitement, pervading the whole lymphatic system.

The constitutions in which tubes mesenterica most readily makes its appearance, are those which are denominated scrophulous. The marks of scrofula we shall not here enumerate; it may be sufficient to observe, that the habit of this disease, and the lymphatic and glandular systems are especially prone to suffer from the exciting causes of disease. This indeed is more or less the case in every individual during growth, as, at this period of existence, the office which these vessels perform in the animal economy, is more important and complicated than in the succeeding stages of life.

Treatment.—The most effectual remedies are necessarily the converse of those which have occasioned the complaint; we otherwise enumerate from the Elements of Dr. Brown: "nourishing exciting milk; three or four meals in the course of the day, composed chiefly of warm milk, pure animal, and by no means weak, soup, mixed with vacation, four or bread; a due temperature, so that a general warmth may be preserved, without producing irritation, or occasioning too copious sweat; avoiding every species of evacuation; good nursing; a proper regulation of the times of sleep, food, and every other circumstance connected with the management of the susceptible and tender condition of infancy; cleanliness; tepid bathing in moderately cold weather, and cold bathing in warm; pure air; being sent out of doors as much as possible, excepting when the weather is damp; and, finally, a judicious attention to desires and propensities; this ought to be carried to such an extent as to obviate, if possible, the most trivial irritation, as by the scratching of a part that itches."

The above are necessarily adapted to the milder forms of the complaint. When the disorder has arrived to a greater extent, the medical is now required in aid of domestic treatment: for although the mesenteric atrophy, unless it is a consequence of defective structure, may at all times be prevented, and in its earlier stages may be remedied, without the aid of drugs; these, at length, come to be absolutely indispensable. It ought, however, to be impressed upon the public mind, that pharmacy, although it may correct the errors, can in no wise become a substitute for, or supply the deficiencies of, regimen.

The objects of the medical practitioner, in the treatment of the disease in question, will be twofold. First, by means of diet, and forcibly stimulating the lymphatics and mesenteric glands; and, 2dly, the preservation of a due and equable excitement in order to obviate the recurrence of the disorder.

[N. B. For the explanation of any terms that may not be familiar, the reader is referred to the articles Anatomy, Physiology, and Medicine.] The first of the above intentions is most speedily and effectually accomplished by mercurial purgatives; and of these colonel (submaris hydrargyri) is generally to be preferred. The benefit which has often resulted from preparations of mercury, particularly in the form of submuriatic acid, has fortunately been accounted for upon very erroneous principles. It is customary to attribute every complaint of childhood, where the stomach and intestines shew marks of derangement, to worms. With the signs of the actual existence of these animalcules, we have already remarked those of tubes mesentericae are, from their affinity, often confounded. Advertisements of inoffensive cures for worms, as indeed for every other complaint, have too frequently been allowed to carry the current before the public: these, for the most part, contain mercury, as the only agent of consequence in their composition; and from the operation of this medicine upon the diseased glands, provided, by accident, the gusa-
INFANCY.

Sect. II.—Water in the head. (Hydrocephalus.)

The discriminating characters of this disease demand serious attention from the medical practitioner; for it cannot be doubted that a great number of children are constantly destroyed by water in the brain, where the nature of the matter has been entirely misunderstood, and the symptoms referred to other sources. Most commonly would it be, on the other hand, hydrocephalus has been very frequently suspected, and the event has proved that the suspicion was destitute of any proper foundation.

Hydrocephalus is generally divided by authors into the internal, or that in which the fluid is contained in the veins of the brain; and external, where the disease is exterior to the substance of this organ, and the fluid is in the cerebral membranes. The first species has likewise been denominated acute, the second chronic. This division, however, is calculated to mislead; not merely on account of the frequent conception of it as a disease, but also in the sense of acute (external and internal) of hydrocephalus, but because the former, as well as the latter, is oftentimes chronic, and by no means necessarily preceded by an inflammatory affection of the parts concerned in its production.

The chronic internal, chronic external, and the acute, species of hydrocephalus, would constitute a classification of the disease, approaching nearer to accuracy than that which has been hitherto adopted; and we shall proceed to give a brief description of each, requesting the reader to recollect that the different kinds are often mixed, and consequently exhibit characters in an almost endless variety.

Chronic internal. This, although overlooked in the ordinary division, is perhaps the most usual form in which the affection presents itself; it arises from the same disposition of habit, and is combined with the disease treated of in the preceding section. More commonly, however, it is in a manner similar to this last; and the same may, perhaps, from accidental circumstances, occur in a habit which makes mesenterica, which would at another have produced hydrocephalus. Its symptoms are less decided than those of the other species. When, however, in children of a sluggish habit, or scrofulous constitution, an unusual drowsiness or stupor is present, the child gradually loses its vivacity and spirits, is indolent, and at length loses all appetite for food and dissipates the condition of the head, the symptoms are less indolent. The fluid only fills the subdural or external meninges. The symptoms, hence, cannot be mistaken for those of hydrocephalus. In the infantile form of hydrocephalus, the infant is observed to have a drowsy appearance, and the head is large; the symptoms, however, are less apparent than in the adult form. The fluid is the same in both cases; and the symptoms are produced by the same cause. The fluid is the same in both cases; and the symptoms are produced by the same cause.

In the practice of the writer of this article, extremely small, and very gradually augmented, doses of digitalis have appeared to restore, in a remarkable degree, the wasted vigour of the vitals. The free use of this very important and active medicine has long been admitted in dropsy, an affection of the highest degree. In plasma mesenterica, we have seen the employment of digitalis very judiciously and successfully; and in the use of the same medicine in the latter case. The importance of the subject is clearly shown by the following cases.

Under these circumstances, on account of the comparative minuteness of the dose, the digitalis is best given in the form of tartar: a preparation which has not hitherto been received into the London Pharmacy.
INFANCY.

mentioned, characteristic of the acute species. This first kind of hydrocephalus is succinctly described by Dr. Heberden, in the following words: "Capitis dolores, manus ad capitum, crebro adnotatur, clamores subiti, dissiemo nervorum, stupor, meatus perturbatus, motus venarum lentes, potestos crecit." He adds, "Iustam est hanc symptomata etiamis capitis molem non fuerit auris."

Chronic external.—The head of an infant at, or soon after, the period of birth exhibits a preternatural size and form; the regular process of ossification and growth is stopped, but the principal part of the external surface of the cranium continues soft and yielding, while not unusually, in the progress of the complaint, an undulation of a fluid may be perceived by touching the head to the subcutaneous tissues of the skull. As the disease continues to advance, the signs of its existence become shortly obvious to the most superficial observation; not only does the head increase to an enormous growth, but parts of it are in a proportionate ratio defective; the limbs do not often acquire a much greater bulk than at birth; at the ordinary period of teething no teeth present themselves; the piercing facies, especially as in other infants; and, indeed, although vitality is preserved, it appears to be a vitality almost entirely unconnected with feeling. In this state of torpid existence life itself is, in some instances, prolonged; but, in others, even a greater number of years. In the Commentaries of Van Swieten, we have the relation of life being maintained under this malady for thirty years: this, however, is an anomaly; and indeed the hydrocephalic patient seldom survives the second year.

Acute hydrocephalus.—The acute, phrenitic, inflammatory, or, as it has been termed by some writers, apoplectic hydrocephalus, is not, like the other species, entirely confined to any constitution. Although most frequent in children under twelve years, it is sometimes observed in adults. It has been divided by Dr. Whytt, and others who have followed him, into three distinct stages: the first of which is involuntary, characterized by a pulsation of much celerity and comparative strength; in the second the pulsations become slower, and more feeble; in the third and last period their rapidity is increased even beyond that of the primary stage; but this increased action is now connected with extreme debility. These different changes in the circulation are not, however, always to be traced even in the acute species of hydrocephalus, in that order which the observations of Dr. Whytt would lead us to suppose.

Obsolescence of the stomach, a general feeling of lassitude, with sometimes a kind of palsy of the limbs, or an affection of them, in some measure similar to that observed in St. Vitus's Dance, if the child has previously been able to walk, sometimes present themselves as precursors of the first, or the inflammatory stage; at other times the feverish state, intolerance of light, violent pains at the head, and vomiting, are the first signs of disorder that are noticed. These symptoms are in some cases connected, according to the observations of Dr. Rush, with an impetuosity of sound; the pain of the head is often confined to one side.

In proportion to its intensity the nausea and vomiting become less urgent, while with the remission of the headache the affections of the stomach are disposed to recur. Respiration at this time is spasmodic and irregular; the bowels are generally so constipated as to require very drastic purgatives, in order to produce evacuations. This stage of the complaint continues sometimes for several days, but is more usually in a shorter period succeeded by the second, which commences by a sudden reduction of the pulse, and other symptoms of irritation. The head now becomes less urgent, torpor succeeds to watchfulness, the infant lets his hands to his head, and frequently utters piercing screams (clamores subiti); a degree of feverish sensations and a morbid susceptibility of light; the little patient lies in an horizontal posture, with the head low, and shows an indisposition to be taken up; the bowels still continue torpid; the symptoms of irritation are of the above-mentioned species; and after these symptoms have lasted from seven to fourteen days, the complaint sometimes appears suddenly to decline. This semblance of returning health is often succeeded by a second period of irritation, and to the final period of the complaint: it is now that the pulse increases in frequency, and oftentimes so quick as not to be counted. Dr. Whytt informs us that in some children he has been able to observe this abstraction in the space of a minute; this extraordinary rapidity, however, does not last through the whole of the day; it comes on and declines with the accesses and remissions of the hectic flux in the head. The eyes at length become insensible to the strongest light, convulsions come on, and life is terminated. The duration of this last period, of stagnation, is very variable. Sometimes the patient is carried oil in less than a week from its commencement; at other times the child lingers in a hectic state for three, four, or six weeks; and Dr. Monro has instances of patients surviving this stage, which it is to be protracted even to the fourth month.

Cause.—The two first species of the complaint are decidedly of a scrophulous nature. They generally come on without any evident cause; at different times the abdominal affections, in the early periods of life, originate from lymphatic debility, without previous excitement in the vessels of the brain to produce the effusion; the last species is perhaps always preceded by an inflammation in the internal vessels of the brain. The immediate cause of this irritation is not, however, in every instance to be detected; it may arise in subjects predisposed, in common with all other inflammations, from the sudden alterations of cold and heat. It has been observed to supervene upon the contagious eruptive affections, especially when these have been unusually violent; and Dr. Beidhoe, in a letter to Dr. Darwin, inquires whether it may not happen more frequently than has been suspected from external injury? Zoonymia.

Treatment.—Evacuations of every kind, purge, cathartics, sudorifics, emetics, general and local blood-letting, as well as the external application of cold, and of blisters to the scalp, with due attention to the erect position of the head, had all, in conjunction or separately, been tried in the acute species of hydrocephalus, but, according to the general report of physicians, without any success, therefore, of the ill success that had attended the common routine of treatment in hydrocephalus, Dr. Dobson, of Liverpool, was induced to make trial of mercurials, with an intention of removing the absorptive organs of the brain, and in this manner removing the extravasated fluid. The event appeared to justify his theory; and we have several cases recorded by this physician and others, in which mercury, carried to the extent of salivation, accomplished a speedy and effectual cure. The following case is from Dr. Percival: "One of my own children, a girl, aged three years and three months, has lately been a severe sufferer under this alarming malady. As soon as the characteristic symptoms of the disease clearly manifested themselves, I laid aside all other remedies, convinced by repeated observation of their insufficiency, and trusted solely, though with much solicitude, to the internal and external use of mercury. In forty-eight hours, signs of amendment appeared, and her recovery was perfected in six days. During this period of administration, calomel were administered, and seven scrupules of unguentum mercuriale fortissimamente rubbed into the leg." With the same design of exciting the absorptive organs, digitalis has recently been employed. "In one child," says Dr. Darwin, "I tried the foxglove in tincture, but it was given with too timid a hand and too late in the disease to determine its effects." In the work of Dr. Reid, to which we referred in a former part of this article, we meet with the following observations: "The universality of lymphatic absorbers is rather conceived than actually demonstrated. Dissection has hitherto not been able to detect these vessels in the brain; analogy, however, favours the supposition of their existence. If that frequent and too fatal disease of young persons, water in the brain, admits of cure, the remedy opens the way for the removal of those indicative of water in the ventricles of the brain, that it is scarcely possible to decide with absolute certainty on the interesting question of the inevitable fatality or remissible nature of hydrocephalus."

If foxglove should prove by future experience to succeed as a remedy for this alarming malady, its modus operandi must be referred to the extraordinary faculty which it possesses of representing the arterial, while it stimulates the absorptive system. Both in the acute and chronic hydrocephalus, it appears to be deserving of a more extensive trial.

To the earliest stage of the former we should, a priori, be disposed to conceive it more applicable than even mercury.

Sect. III.—Worms. ( Vermes.)

The marks by which the presence of worms is indicated are confessedly at times, both in the infant and adult, obscure and equivocal. In the majority of cases, however, the phenomena which they present require only for their detection a careful and discerning scrutiny.
INFANCY.

In persons affected with worms, the constipation in general has a particularly vivid and distinct appearance, very different from that which characterizes the diarrhoea. Impeded nutrition of the alimentary canal, as in mesenteric, and hydrocele.

The eyes become dull, the pupil dilated, but not averse to light, as in hydrocele, the upper lip swelled, the sides of the nostrils enlarged, and there is always a constant palpable vitching of their internal membrane. The breath is remarkably offensive, saliva is secreted in unusual abundance; during sleep there is most generally a rolling of the teeth, and epileptic affections are by no means uncommon; the pulse is intermittent, the celebrous irritation is not always of the hectic kind, the appetite is often voracious, lancinating pains are complained of in the bowels and head, and tenesmus, attended with a distressing irritation about the anus. This is, especially from some species of worms, exceedingly frequent. Cough is not uncommon. These last, however, are symptoms which may be met with in the adult than in the child. See Medicine.

Caus.—The tumid belly, blunted contour, and swelled upper lip, says Dr. Darwin, are concomitant circumstances attending the reaction of the absurd system, which is therefore to be esteemed the remote cause of the generation of worms. Worms, however, are often produced through the medium of intestinal viscidities, and the action of the alimentary vesels. The immediately exciting causes are some of those already mentioned as productive of mesenteric atrophy, more especially the reception into the stomach of indigestible substances. Dr. Darwin, indeed, supposes, that not merely the nuxis of worms is thus formed from aliment incapable of assimilation, but that these animalcules are actually received from without: for this opinion, however, there does not appear any foundation. Worms are actually engendered in the alimentary passage.

Treatment.—Emetics; mercurial purgatives; chalybeates; vegetable bitters; avoid aliments of the melon kind. For an account of the different kinds of worms, and specific antphilologies, consult the articles Medicine, and Materia Medica.

Sect. IV.—Rickets. (Rachities. Atrophia Infantilis.)

This is likewise an affection of the lymphatic system. Every one knows the characters by which it is marked. An infant with a large head, proterbant forehead, swellings in the smaller joints, depressed flattened ribs, enunciated limbs, and tubm abdomen, is decidedly rickety. These symptoms, in common with the other affections of infants, usually make their appearance before the second year. The first indication of a rickety tendency is a remarkable lassitude of the muscular fibre: disinclination to exertion follows; general inactivity of the limbs, above enumerated, shortly supervene, followed by hectic, cough, confirmed atrophy, death, or permanently distorted limbs.

Causes.—Obligation, most commonly of an hereditary nature, constitutes the predisposing cause to rickets. Bad air, bad nursing, improper diet, uncleasenes, and damp, are its exciting causes. Hoffmann describes the proximate cause to be a deficient supply of nervous influence to the spinal marrow, producing the deficient nutrition of parts. Dr. Cullen supposes, a deficiency of bone matter in the fluids constituting the intestines. A more correct account, however, of the essentials of rickets, would make it to consist in deficient excitement or power in those vessels, by the action of which osseous matter is thrown out, and hence constituting. Treatment.—Indication 1st. To cleanse the first passages from obstructions. Method of medicating: emetics, cathartics, chalybeats.

Indication 2d. To restore due energy to the structures disturbed. M. M. chalybeats, exercise, bathing.

Sect. V.—Disorder in the bowels. (Diarrhoea infants.)

Among the morbid infancies in the yearly catalogue of every medical practitioner, diarrhoea occupies a conspicuous situation. The griping, green, and otherwise discoloured stools, putrid in the abdomen, with drawing up of the knees towards the stomach, severe crying, febrile irritation, and a greater or less degree of actual convulsion, are perhaps the most common among the diseases of infancy.

Contractions, as we have already observed, are almost invariably occasioned by improper diet. Dr. Darwin gives us the following relation: "A child of a week old, which had been taken from the breast of its dying mother, and had by some uncommon error been suffered to take no food but water-gruel, became sick and gripped in 24 hours, was convulsed on the second day, and died on the third." That among the poor children of Derby who are thus fed, few hundred are starved into scrofula, and either perish or live in a state of wretched debility. Zoonomia.

Treatment.—Colonel with rhubarb, and more spicy substances, is to be immediately given, which is to be followed by antichris, such as prepared chalk and magnesia. With these are to be connected, according to the violence of the disorder, emetics, cathartics, such as cinnamomum, isatinum, and opium. Sometimes it is necessary to give an emetic. In all cases indigestible food is to be avoided.

Sect. VI.—Affections occasioned by teething. (Denitis.)

Pains in the form of convulsions, frequent and sudden startings, especially in sleep, crotions on the skin, disorders of the stomach and bowels, cough, and hectic fever, are not unfrequently occasioned by the process of toothing. Dr. Darwin conjectures, that "the pain of toothing often begins much earlier than is suspected," and that the apparent cause of the disease is in reality its cure, as the convulsions, which are often accompanied with violent and then by far the most alarming of the above symptoms, are commonly relieved when the gum swells and becomes inflamed; at other times a diarrhoea supervenes, which is generally esteemed a favourable circumstance.

In difficult dentition, the pains in the head, convulsions, vomiting, and hectic, sometimes give rise to the suspicion of hydroceleps; from this, however, the disease in question may generally be distinguished, with facility by the case with which, in the last case, the bowels are evacuated; by the inflammatory redness of the gum, and by the pupil of the eye being dilated in an obscure, and constatated in a vivid light, the contrary of which takes place in hydroceleps.

Treatment.—Frequent doses of rhubarb, and the fluid convulsating and mitigating the toothing cough. The gums are to be banded in all cases where the redness and swelling are considerable. This practice can indeed never be objectionable, and the gums thus bandaged, are unefficacious while the cause remains.

Sect. VII.—Group. (Cyananche trachealis.)

The characteristics, or pathomathic symptoms of this disease are, violent prostration, loud and stridulous cough, with the emission of a sound of a peculiar nature, which has been compared to the croak of a young cock.

These symptoms sometimes supervene upon the common precursors of violent inflammation: at other times the disease is formed without previous warning, and has been known to prove fatal in a very few hours from its apparent commencement. If the disease is thus early terminated in the man, the disorder frequently runs on for the space of six days, and terminates for the most part by crisis, with the evacuation of much pale urine.

Causes.—The croup is an inflammation of the upper part, as the peripneumy is of the lower part of the same organ, viz. the trachea or windpipe. It originates from the same sources as other inflammation. The circumstances of the most frequent and tendency in infants, appears to be owing to the extremely disproportionate smallness of the glottis at that period of life. The cause of death, when it happens suddenly, is a deposition of concreted mucus (consequent upon the inflammation), which laces the trachea, and fills up the bronchial cavi- ties. Independently, however, of this circumstance, sudden death may be occasioned by the great loss of power in the musculorous fibres of the glottis, induced by the previously high excitement, "infantes enim mirum indicationis viscitutiam, brevissimis temporibus ruptum, expirarunt." Treatment. — The nature of the effectual, must be speedy and decisive. Emetics: copious bleeding by leeches, applied near to the patient affected; blisters; warm bath; antimonials.

Recently, calomel in large doses has been tried, with success; but yet not sufficiently proved useful in consequence of its extraordinary power in rapidly reducing arterial excitement.

N. B. Croup, in some instances, assumes more of the authentic than of the inflamma- tory nature; and in this case the disorder of the glottis is often protracted to a longer period. The treatment in this latter species requires to be stimulating. Calomel: opiates; blisters; volatile embrocations to the throat; nourishing diet.

For those diseases of young persons which often require local, in connection with general treatment. The distortions of the space, affections of the eyes, scrofulous swellings of lymphatic glands, &c. consult the articles Medicine, and Surgery.

For eruptive and contagious diseases, see Medicine, and Surgery.
INF on which they are presumed capable of acting with reason and discretion; in our law, the full age of man or woman is 21 years. 3 Bl. Abr. 118.

The ages of male and female are different for different purposes: a male at 12 years of age may take the oath of allegiance; at 14 is at discretion, and therefore may consent or disagree to marriage, may choose his guardian, and if his discretion is actually proved, may make his testament of his personal estate; at 17 he may be a procurator or an executor; and at 21 he is in his own disposal, and may alien his lands, goods, and chattels. A female at seven years of age may be betrothed or given in marriage; at nine is entitled to dowery; and at 12 is of years of maturity, and therefore may consent or disagree to marriage, and if proved to have sufficient discretion may bequest her personal estate at 14 is at years of legal discretion, at 17 she may choose a guardian; at 17 be executrix; and at 21 may dispose of herself and her lands. 1 Black. 463.

An infant is capable of inheriting, for the law presumes him capable of property; also an infant may purchase, because it is intended for his benefit, and the freedhold is in him till he discharges thereto, because an agreement is proper for his benefit, and he is bound for his benefit, and because the freedhold cannot be in the grantor contrary to his own act, nor can be in abeyance, for then a stranger would not know against whom to demand his right; and if at full age infant agrees to the purchase, he cannot afterwards avoid it; but if he dies during his minority his heirs may avoid it, for they shall not be bound by the contracts of a person who had wanted capacity to contract. Co. Lit. 2.

As to infants being witnesses, there seems to be no fixed time at which children are excluded from giving evidence; but it will depend in a great measure on the sense and understanding of the children, as it shall appear on examination in court. Bull. N. P. 293.

And where they are admitted, concurrent testimony seems particularly desirable. 4 Bla. 279.

An infant is not bound by his contract to deliver a thing; so if one deliver goods to an infant upon a contract, &c., knowing him to be an infant, he shall not be chargeable in trover and conversion, or any other action for them; for the infant is not capable of any contract but for necessaries, therefore such delivery is a gift to the infant; but if an infant, without any contract, willfully takes away the goods of another, trover lies against him; also it is said, that if he takes the goods under pretence that he is of full age, trover lies, because it is a willful and fraudulent trespass. 1 Sid. 129.

Infants are disabled to contract for any thing but necessaries for their person, suitable to their degree and quality; and what is necessary must be left to the jury. Co. Lit. 172.

An infant, knowing of a fraud, shall be as much bound as if of age. 13 Vin. Abr. 536.

But it is held that this rule is confined to such acts only as are voidable; and that a warrant of attorney given by an infant being absolutely void, the court will not confirm it, though the infant appeared to have given it, knowing it was not good, and for the purpose of collusion.

As to acts of infants being void, or only voidable, there is a diversity between an actual delivery of the thing contracted for, and a bare agreement to deliver it; the first is voidable, but the last absolutely void.

An infant, for his own security for necessaries for him, is chargeable for them, unless provided before marriage; in which case he is not answerable, though she wore them afterward. 1 Str. 108.

An infant is also liable for the nursing of his lawful child.

Where goods are furnished to the son, he is himself liable if they are necessaries. If tradesman deal with him, and he undertakes to pay them, they must resort to him for payment; but if they furnished the infant on the credit of his father, the father only is liable. 2 Esp. 471.

With respect to education, &c. Infants may be charged, where the credit was given bona fide to them. But where the infant is under the parent's power, and living in the house with them, he shall not be liable even for necessaries. 2 Black. Rep. 1325.

If a tenant lives with an under age, for clothes to an extravagant degree, he cannot recover; and he is bound to know whether he deals at the same time with any other tenant. 1 Esp. Rep. 212.

A factor, who endeavours to get money from an infant, may settle the contract; one lends money to an infant to pay a debt for necessaries, and he pays it, although he is not bound in law, it is said he is in equity; but if the infant misapplies the money it is at the peril of the lender.

A promissory note given by an infant for goods or lodging, and for teaching him a trade, is valid, and will support an action for the money. 1 T. R. 41.

And debts contracted during infancy are good considerations to support a promise made to them when a person is of full age; but the promise must be express. 2 Esp. Rep. 164.

Legacies to infants cannot be paid either to them or their parents.

An infant cannot be jurors, neither can he be an attorney, bailiff, factor, or receiver. Co. Lit. 172.

By the custom of London an infant unmarried, and above the age of 14, if under 21, may bind himself to apprentice to a freeman of London, by indenture with proper covenants, which covenants, by the custom of London, will be as binding as if of age.

If an infant draws a bill of exchange, yet he shall not be liable on the custom of merchants; but he may plead infancy in the same manner as he may to any other contract.

An infant cannot sue but under the protection and joining of his guardian; but he may sue either by his guardian, or his next friend, who is not his guardian. Co. Lit. 135.

An action on an account stated will not lie against an infant, though it should be for necessaries. Co. Lit. 172.

INFINITELY, of INFINITELY GREAT LINE, in geometry, an indefinite or indeterminate line, to which no certain bounds, or limits, are prescribed.

INFINITESIMALS, among mathematicians, are defined to be infinitely small quantities.

In the method of infinitesimals, the element, by which any quantity increases or decreases, is supposed to be infinitely small, and is generally considered for its finite or assigned terms, some of which are infinitely less than the rest, which being neglected as of no importance, the remaining terms form what is called the difference of the proposed quantity. The terms that are neglected in this manner, as infinitely less than the other terms of the element, are the very same which arise in consequence of the acceleration, or retardation, of the generating motion, during the infinitely small time in which the element is generated; so that the remaining terms express the elements that would have been produced in that time, if the generating motion had continued uniform; therefore those differences are accurately true without actually being even an infinitesimal small error, and agree precisely with those that are deduced by the method by fluxions.

For example (see Plate Miscell. fig. 136), when DG, the increment of the base AD, of the triangle ADE, is supposed to become infinitely little, the trapezium DGH, consisting of the simultaneous increment of the triangle) consists of two parts, the parallelogram EG, and the triangle EIH; the latter of which is infinitely less than the former, and the ratio being that of one-half DG to AD; therefore, according to this method in fluxions, the part EIH is neglected, and the remaining part, viz. the parallelogram EG, is the difference of the triangle ADE; which may be shown, that EG is precisely that part of the increment of the triangle ADE which is generated by the motion with which this triangle flows, and that EIH is the part of the same increment which is generated, and is the consequence of the acceleration of this motion, and is the base, by flowing uniformly, acquires the augment DG, whether DG be supposed finite or infinitely less.

Example 2. The increment of the rectangle BEMHD (fig. 137) of the rectangle AE, consists of the parallelogram EG, EM, and IA; the last of which, IA, becomes infinitely less than EG, or EM, when DG and IA, the increments of the sides, are supposed infinitely small, because IA is supposed to be to EG as EA to AE, and to EM as DG to AD; therefore, being neglected, the sum of the parallelograms EG and EM is the difference of the rectangle AE; and the sum of EG and EM is the space that would have been generated by the motion with which the rectangle AE flows continued uniformly, but that IA, is the part of the increment of the rectangle which is generated in consequence of the acceleration of this motion, in the time that AD and IA, by flowing uniformly, acquire the augment DG and IA. The same may be observed in propositions wherein the fluxions of quantities are determined, viz. the manner of investigating the differences, and the discussion of quantities, in the method of infinitesimals, may be deduced from the principles of the method of fluxions. For instead of neglecting EIH because it is infinitely less than EG, (according to the usual manner of
soning in that method), we may reject it; because we may thence conclude, that it is not produced in consequence of the generating motion DG, but of the subsequent variations of this motion. And it appears why the conclusion in the method of infinitesimals is not to be represented as if they were only near the truth, but are to be held as accurately true.

In order to render the application of this method easy, some analogous principles are admitted, as that the infinitely small elements of a curve are right lines, or that a curve is a polygon of an infinite number of sides, which being produced, give the tangents of the curve; and by their inclination to each other measure the curvature. This is as if we should suppose, when the base flows uniformly, the ordinate flows with a motion which is uniform for every infinitely small part of time, and increases or decreases by infinitely small differences at the end of every such time.

But however convenient this principle may be, it must be applied with caution and art on various occasions. It is usual therefore in many cases, to resolve the element of the curve into two or more infinitely small right lines, if it is necessary, if we would avoid error, to resolve it into an infinite number of such right lines, which are infinitesimals of the second order. In general, it is a postulatum in this method, that we may descend to the infinitesimals of any order whatever, as we find it necessary; by which means any error that might arise in the application of it may be discovered and corrected by a proper use of this method itself. For an example of this, see Macaulay's Fluxions.

INFLAMMABILITY, that property of bodies which disposes them to kindle or catch fire. See CALCULUS, CHEMISTRY, &c.

INFLAMMATION. See Surgery, and Medicine.

INJECTION, or point of injection, in the higher geometry, is the point where a curve begins to bend a contrary way. See ca

To determine the point of injection in curves, whose semi-ordinates CM, CM' (Pl. Misc. fig. 1.54) are drawn from the fixed point C; suppose CM to be infinitely near C, and make \( \alpha = \frac{\pi}{2} \); let \( \tau \) touch the curve in M. Now the angles \( \alpha C T, \alpha C M' \), are equal; and so the angle \( \alpha C \), while the semi-ordinates increase, does decrease, if the curve is concave towards the centre C. and increases if the convexity turns towards it. Whence this angle, or, which is the same, its measure, will be a minimum or maximum, if the curve has a point of injection or retrogression; and so may be found, if the arch \( \alpha H \), or fluxion of it, be made equal to 0, or infinity. And in order to find the arch \( \alpha H \), draw the angle \( \alpha T \), equal to \( \alpha C \).

Again, draw the arch \( \alpha H \) to the radius \( CH \); then the small right lines \( CM \), \( CM' \), are parallel; and so the triangles \( O L H, \) \( mL \), are similar; but because \( H \) is also perpendicular to \( \alpha L \), the triangles \( \alpha L H, \) \( mL \), are also similar, whence \( \frac{\alpha L}{\alpha H} = \frac{\alpha L}{\alpha H} \); that is, the quantities \( \alpha H, \) \( \alpha L \), are equal. But \( \alpha H \) is the fluxion of \( H \), which is the distance of \( C \) to \( H \); and \( \alpha L \) is a negative quantity, because the time \( \alpha T H \) is the duration, \( \alpha H \) decreases; whence \( \alpha H - \alpha L = \frac{\alpha H}{\alpha L} \), which is a general equation for finding the point of injection, or retrogression. See Fluxions.

INFORMATION, in law. An information may be defined an accusation or complaint exhibited against a person for some criminal offence, either immediately against the king, or against a private person, which, from its enormity or dangerous tendency, the public good requires to be restrained and punished. It differs principally from an indictment in this, that an indictment is an accusation found by the oath of 12 men, but in information is only the allegation of the officer who exhibits it. 3 Bac. Abr. 164.

Informations are of two kinds: first, those which are partly at the suit of the king, and partly at the suit of a subject; and, secondly, such as are only in the name of the king: the former are usually brought upon solemn statutes, which inflict a penalty on conviction of the offender, and are, by the use of the king, and another to the use of the informer; and are called qui tam, or popular actions, only carried on by a criminal instead of a civil process.

Informations that are exhibited in the name of the king alone are also of two kinds: first, those which are truly and properly his own suits, and filed ex officio by his own immediate officer, the attorney-general; secondly, those in which, though the king is the nominal plaintiff, it is at the relation of some private person, or common informer; and they are filed by the master of the crown office, under the express direction of the court. The objects of the king's own prosecutions, filed ex officio by the attorney-general, are properly such enormous misdemeanours as peculiarly tend to disturb or endanger the government. The objects of the other species of informations, filed by the master of the crown office, under the complaint or relation of a private subject, are any gross and notorious misdemeanours, riots, batteries, libels, or other immoralities, of an atrocious kind, not likely to disturb or endanger the government, but which, on account of their magnitude or pernicious example, deserve the most public animadversion. And when an information is filed either thus, or by the attorney-general ex officio, it must be tried by a petty jury of the county where the offence arises; after which, if the defendant is found guilty, he must resort to the court of king's bench for his punishment. 4 Black. 308.

If a common informer should willingly delay his suit, or discontinuance, or be negligent, or shall have a verdict or judgment against him, he shall pay costs to the defendant. 18 Eliz. c. 5.

And in the court of king's bench, particularly if the defendant shall appear and plead to the issue, and the prosecutor shall not at his own costs, within a year after issue joined, procure the same to be tried; or if a verdict pass for the defendant, then the informer profiting thereby, shall not be entitled to enter the said court of king's bench may award the defendant his costs, unless the judge shall certify that there was a reasonable cause for exhibiting such information; and if the informer shall not, in three months after such costs taxed, and demand made, pay the same, the defendant shall have the benefit of the recognition, to compel him thereunto. 4 and 5 W. c. 18.

INFRALAPSIANS, in church history, an appellation given to such predestinarians as think the decrees of God, in regard to the salvation or condemnation of mankind, were formed in consequence of Adam's fall.

INFUSION, a method of obtaining the virtues of plants, roots, &c. by steeping them in a hot or cold liquid.

INFUSORIA, in natural history, minute simple animals, seldom visible to the naked eye. When water is examined with the microscope, particularly that which has long been stagnant, and has vegetable matter growing in it, or water in which vegetables have been immersed, thousands of minute animals have been discovered, which have been arranged together in this order. When wheat that is richly infused in water, small eel-shaped worms are discovered, which were the cause of the disease. Wheat thus injured is proper for the mill, whereas, if it is not, it is convenient to the use of the king. The grains are brown, shrivelled, and of irregular form; each contains one or more of these worms, which lie dormant as long as the grain is dry; but as soon as it is moistened by being washed, or otherwise, the worms are revivified, feed on the flour, and lay their eggs. Such grain vegetables, the young, as soon as they are hatched, eat their way up the stem, and bury themselves in the young shoots of wheat.

INGRESS, in astronomy, signifies the sun's entering the first scrobule of one of the four cardinal signs, especially Aries.

INGROSSER. See Forestalling.

INHALER, in medicine, a machine for steaming the lungs with warm water, recommended by Mr. Mudge in the cure of the carbunular cough. The body of the instrument resembles a porter-pot, holds about a pint of water, being fixed to the side of it, is hollow. In the lower part of the vessel, where it is soldered to the handle, is a hole, by means of which and three others on the upper part of the handle, the water, when it has been heated, will rise to the same level in both. To the middle of the cover a flexible leather tube, about six or seven inches long, is fixed, with a mouth-piece of wood or ivory. In the cover there is a valve fixed, which opens and shuts the communication between the upper and internal part of the inhaler and the external air. This valve is extremely simple: being formed only of a short tube descending forwards from the cover, and having a braciate a small hook upon which a ball of cork plays. When the mouth is applied to the end of the tube in the act of inspiration, the air rushes into the handle, and up through the body of warm water, and the lungs become, consequently, filled with hot vapour. In expiration, the mouth being still fixed to the tube, the breath, together with the steam on the surface of the water in the inhaler, is forced up through the valve in the same manner.
Injunctions issue out of the courts of equity in several instances. The most usual injunction is to stay proceedings at law; as, if one man brings an action at law against another, and a bill is brought to be relieved either against a penalty, or to stay proceedings at law, or some equitable circumstances, of which the party cannot have the benefit at law. In such case the plaintiff in equity may move for an injunction either an attachment, or praying a demurrer, or praying a further time to answer; for it being suggested in the bill that the suit is against conscience, if the defendant is in contempt for not answering, or praying time to answer, it is contrary to conscience to proceed at law in the mean time; and therefore an injunction is granted of course; but this injunction only stays execution touching the matter in question; and there is always a clause giving liberty to call for a plea to proceed to trial, and for want of which to obtain judgment; but execution is stayed till answer, or farther order. 3 Bac. Abr. 173.

When a bill in chancery is filed in the office of the six clerks, if an injunction is prayed therein, it may be had, at various stages of the cause, to the circumstances of the case. If the bill is to stay execution upon an oppressive judgment, and the defendant does not put in his answer within the time allowed by the rules of the court, an injunction will issue; and when the answer comes in, the injunction can only be continued upon a sufficient ground appearing from the answer itself. But if an injunction is wanted to stay waste, or other injuries of the plaintiff, the court may make him file the bill, and a proper answer supported by affidavits, the court will grant an injunction immediately; to continue till the defendant shall make some further order, or hearing it, and when the answer comes in whether it shall then be dissolved, or continued till the hearing of the cause, is determined by the court upon argument, drawn from considering the answer and affidavits together. 3 Bac. 433.

The methods of dissolving injunctions are various; when the answer comes in, and the party has proved his content, by paying the costs of the attachment, if there is one; he obtains an order to dissolve nisi, and serves it on the plaintiff's clerk in court; this order takes notice of the defendant's having fully answered the case of the suing party; and when the whole estate thereof, and being regularly served, the plaintiff must shew cause at the day; or the defendant's counsel, where there is no probability of shewing cause, may move to make the order absolute, unless cause, sitting the court. 3 Bac. Abr. 177.

If the plaintiff who has an injunction die pending the suit, in strictness the whole proceedings are abated, and the injunction with it; but the court may, if they think fit, not take out execution without special leave of the court; he must move the court for the plaintiff to revive his suit within a limited time, or the injunction to stand dissolved; and if the defendant does not do this within the time, then the suit is not revived, the party takes out execution. There are some instances where a plaintiff may move to revive his injunction; but that rarely happens, so it is rarely granted, especially where the injunction has been before dissolved: but where a bill is dismissed, the injunction and every thing else are gone, and execution may be taken out the next day. 3 Bac. Abr. 178.

INJURY, an injury to a man's person or goods. The law will suffer a private injury rather than a public evil; and the act of God or the law does injury to none. 4 Rawle, 129.

INK. There are two principal kinds of ink, writing and printing ink.

Writing-ink. When an infusion of gallnuts some solution of sulphate of iron (green copperas) is added, a very dark blue precipitate takes place.

Printing-ink. A black paint, composed of lamp-black and linseed or saet oil boiled, so as to acquire considerable consistence and tenacity. The art of preparing it is kept a secret; but the obtaining good lamp-black appears to be the chief difficulty in making it. The ink used by copper-plate printers differs from the last only in not being so much boiled, and the black which is used being Frankfort black.

Sympathetic inks are such as do not appear after they are written with, but which may be made to appear at pleasure. When dry, no writing will be visible. When you want to make it appear, wet the paper with a solution of equal parts of gum arabic and water, and the letters will immediately appear of a brown colour. Even exposing the writing to the vapours of these solutions will render it apparent.

2. Write with a solution of gold in aqua regia, and let the paper dry gently in the shade. Nothing will appear; but draw a sponge over it wetted with a solution of this in aqua regia, the writing will immediately appear of a purple colour.

3. Write with an infusion of galls, and when you wish the writing to appear dip it into a solution of green vitriol; the letters will appear black.

4. With diluted sulphuric acid, and...
nothing will be visible. To render it so, hold it to the fire, and the letters will instantly appear black.

5. If on emons, or onions, a solution of sal ammoniac, green vitriol, &c. will answer the same purpose, though not so easily, nor with so little heat.

6. Green sympathetic ink. Dissolve cobalt in nitric acid, and write with the solution. The letters will be invisible till held to the fire, when they will appear green, and will disappear completely again when removed into the cold. In this manner they may be made to appear and disappear at pleasure.

A very pleasant experiment of this kind is to make a drawing representing a winter scene, in which the trees appear void of leaves, and to paint the leaves on with this sympathetic ink; then, upon holding the drawing near to the fire, the leaves will begin to appear in all the verdure of spring, and will very much surprise those who are not in the secret.

Dissolve sympathetic ink. Dissolve cobalt in nitric acid; precipitate the cobalt by potash; dissolve this precipitated oxide of cobalt in acetic acid, and add to the solution one-eighth of common salt. This will form a sympathetic ink, that, when cold, will be invisible, but will appear blue by heat.

Ink, removing stains of. The stains of ink on cloth, paper, or wood, may be removed by almost all acids; but those acids are to be preferred which are least likely to injure the texture of the stained substance. The nitric acid, diluted with five or six times its weight of water, may be applied to the spot, and, after a minute or two, may be washed off, repeating the application as often as may be found necessary. But the vegetable acids are attended with less risk, and are equally effectual. A solution of the oxalic, citric (acid of lemons), or tartaric acids, in water, may be applied to the most delicate fabrics without any injury to the fabric, and the same solutions will discharge writing, but not printing-ink. Hence they may be employed in cleaning books which have been defaced by writing on the margin, without injuring the text. If the juice of an orange is laid upon a Stuart's ink-stain, the stain will be removed, but not so easily as the concrete acid of lemons, or citric acid.

INNS AND INNKEEPERS. Common inns were instituted for passengers; and the duty of innkeepers extends chiefly to the entertaining and harbouring of travellers, finding them victuals and lodging, and securing the goods and effects of their guests; and therefore if one who keeps a common inn refuses to receive a guest as a guest into his house, or to find him victuals or lodging, upon his tendering a reasonable price for the same, he is not only liable to render damages for the injury in an action on the case, but to pay the damages of the party grievous, but also may be indicted and fined at the suit of the king.

Dyer, 158.

In return for such responsibility the law allows him to retain the horse of his guest until paid for his keep; but he cannot retain such horse, unless the owner, though he may retain his goods for such bill, neither can he detain one horse for the food of another. 1 Bulst. 267, 247.

An innkeeper, however, is not bound to receive the horse, unless the master lodge there also. 2 Brow. 218.

Necessities in law bound to furnish provisions unless paid beforehand. 9 Co. 87.

If an innkeeper makes out unreasonable bills, he may be indicted for extortion; and if either he or any of his servants knowingly sell bad wine or bad provisions, they will be responsible in an action of debt.

Any person may set up a new inn, unless it is inconvenient to the public, in respect of its situation, or its increasing the number of inns, not only to the prejudice of the public, but also to the hindrance and prejudice of other ancient and well-governed inns; for the keeping of an inn is no franchise, but a lawful trade, open to every subject, and therefore there is no need of any licence from the king for that purpose. 2 Rolbr. 84.

An innkeeper is distinguished from other trades in that he cannot be a bankrupt; for though he buys provisions to be spent in his house, yet he does not properly sell them, but sells them as fast as he can; therefore his expenses will not, in the same manner, appear as he thinks reasonable; and the attendance of his servants, furniture of his house, &c. are to be considered; and the statutes of bankruptcy only mention merchants that use to buy and sell goods for others; he does not; he lives by buying and selling; but the contracts with innkeepers are not for any commodities in specie, but they are contracts for house-room, trouble, accommodation, and necessaries, and therefore coincide within the design of such words, since there is no trade carried on by buying and bartering commodities. 1 Joes. 437.

But where an innkeeper is a chapman also, and buys and sells, he may, on that account, be a bankrupt, though not barely as an innkeeper, and this has been frequently seen. 7 Vin. 567.

Innkaters are clearly chargeable for the goods of guests stolen or lost out of their inns, and this without any contract or agreement for that purpose; for the law makes them liable in respect of the reward, as also in respect of their being places appointed and allowed by law for the accommodation and security of travellers and traders. Dyer, 205.

But if a person comes to an innkeeper, and desires to be entertained by him, which the innkeeper refuses, because his house is already full; whereupon the party says he will shift among the rest of his guests, and there he is robbed, the host shall not be charged. Dyer, 158.

If a man comes to a common inn to harbour, and desires that his horse may be put to grass, and the host gives him to grass accordingly, and the horse is stolen, the host shall not be charged; because by law the host is not bound to answer for any thing out of his inn, but only for those that are in hospital with him. 8 Co. 31 d.

Innkeepers may detain the person of the guest who eats, or the horse which eats, till payment, and he may do without any agreement for that purpose; for men that get their livelihood by entertainment of others, and who are not charged with the keeping the goods of others, they have a right to detain the property of another, in case of non-payment, nor make such disadvantageous and impedient a supposition, that they shall not be paid; and therefore the law annexed such a condition without the agreement of the parties. Rolbr. 83.

By the custom of London and Exeter, if a man commits a horse to a hostler, and he eats out of the price of his head, the better may take him as his own, upon the reasonable apprehension of four of his neighbours; but the innkeeper has no power to sell the horse, by the general custom of the whole kingdom.

But it has been held, that though an innkeeper in London may, after long keeping, have the horse appraised, and sell him; yet when he has, in such case, had him appraised, he cannot justify the taking him to himself, at the sole expense it was appraised at. 1 Vin. 233.

INNS OF COURT, are so called, because the students therein study the law, to enable them to practise in the courts at Westminster, and also because they use all other gentles of life, and may render them better qualified to serve the king in his court. Fortesc. c. 49.

INNOMINATA OSSA. See Anatomy.

INNUENDO, is a word used in declarations and law proceedings, to ascertain a person's name or name of the named before; as to say he (innuendo the plaintiff) did so and so, when there was mention before of another person.

Innuendo may serve for an explanation where there is plaintiff matter, but never for a new charge; and it may signify what is already expressed, but cannot add or enlarge the importance of it. 2 Salk. 513.

INOCULATION. See Medicine.

INOCULATION, or Barking. See Grafting.

INOLITHUS, in mineralogy, a stone consisting of carbonate of lime, carbonic acid gas, and a little iron; entirely soluble in nitric acid with effervescence; fibrous, parasyte, soft, lightish, breaking into indeterminate fragments. There are several species of the Bollanlitous there are three varieties; the nat'sar, so called from its rich satiny lustre, is found in Russia, Poland, Germany; Satine, and Willow, the fibres straight and a little curved. It is found also about a mile from Abston in Cumberland, washed by the river Tyne, near the level of its bed; colour white, with sometimes a rosy tinge from a diffused oxide of iron, and transmits light from the edges, or in thinner pieces: fracture in the direction of the striæ fibrosum, straight or curved; specific gravity 2.17, contains carbonic acid 47, carbonate of lime 50, water of crystallization 2, and a small portion of iron.

INORDINATE PROPORTION, is where there are three magnitudes in one rank, and three others proportion to them in another, and you compare them in a different order. Thus suppose the numbers in one rank to be 2, 3, 9; and those of the other rank 8, 24, 36; which are compared in a different order, viz. 2; 3: 24: 36; and 3: 9: 8: 24. Then rejecting the mean terms of each rank, you conclude 2: 9: 36: 81; and...
In the church of Rome, a tribunal in several Roman-catholic countries, erected by the popes for the examination and punishment of heretics.

This court was founded in the 12th century by Innocent III. and his followers, who were sent by pope Innocent III. with orders to excite the catholic princes and people to extirpate heretics, to search into their number and quality, and to transmit a faithful account thereof to Rome. Hence they were called inquisitors; and this gave birth to the formidable tribunal of the inquisition, which was received in all Italy, and the dominions of Spain, except the kingdom of Naples, and the Low-countries. See Act of Faith.

INROLLMENT, in law, is the registering, recording, or entering in the rolls of the chancery, king's-bench, common-pleas, or exchequer, or by the clerk of the peace in the records of the quarter-sessions, of any lawful act; a statute or recognizance acknowledges a deed of bargain and sale of land, and the like; but the inrolling a deed does not make it a record, though it thereby becomes a deed recorded; for there is a difference between a matter of record, and a thing recorded to be kept in memory; a record being the entry in parchment of judicial matters connected with court of record, and whereof the court takes notice, whereas an inrolling of a deed is a private act of the parties concerned, of which the court takes no cognizance at the time of doing it, although the court permits it. 2 Litt. Abr. c. 9.

By Stat. 27 H. VIII. c. 16, no lands shall pass, whereby any estate of inheritance or freedom shall take effect, or any use thereof be made, by reason only of any bargain and sale thereof, except the bargain and sale be made by writing indented, sealed, and within six months enrolled in one of the king's courts of record, Westminster, or elsewhere within the county where the lands lie, before the clerk of the peace, and one or more justices. But by 5 Eliz. c. 26, in the counties palatine, they may be enrolled at the respective courts there appointed.

Every deed before it is enrolled is to be acknowledged to be the deed of the party, before a master of chancery, or a judge of the court wherein it is enrolled, which is the officer warranting for inrolling the same; and the inrolling of a deed, if it is acknowledged by the grantor, shall be a good proof of the deed itself when tried. 2 Litt. Abr. 69.
very small circles may be nicely drawn with them, as they are to be conveniently moved and turned about in the hand, by a short steel shaft.

III. Of the drawing pen and pencil. The drawing-pen is only the common steel pen at the end of a brass rod, or shaft, of a convenient length, to be held in the hand for drawing all kinds of straight lines by the edge of a rule. The shaft or handle has a screw in the middle part; and, when unscrewed, there is a fine steel round pin or point, by which you make as nice a mark or drawing as you please for terminating your lines in curious draughts.

The black-lead pencil, if good, is of frequent use for drawing straight lines, and for supplying the place of the drawing-pen, where lines (as in ladies) are necessary; it is also often substituted for the common pen in writing, figuring, &c. Because in all cases, if what be drawn with it be not right, or does not please, it may be very easily rubbed out with a piece of crumb bread, and the whole redrawn.

IV. Of the protractor. The protractor is a semicircle of brass, A B D, divided into 180 degrees, and numbered each way from every other to the semicircle by 10°, 20°, 30°, &c. The central line is the external edge of the protractor’s diameter, or straight side, sloped down to the under side, and is generally called a central edge; in the middle with which to draw a line, or line, or line, in the centre, for the side of the protractor. One or other of the protractors or the other, or both, is used in practice.

IV. Of the protractor. The protractor is a semicircle of brass, A B D, divided into 180 degrees, and numbered each way from every other to the semicircle by 10°, 20°, 30°, &c. The central line is the external edge of the protractor’s diameter, or straight side, sloped down to the under side, and is generally called a central edge; in the middle with which to draw a line, or line, or line, in the centre, for the side of the protractor. One or other of the protractors or the other, or both, is used in practice.

The protractors in form and necessary; it is also often substituted for the common pen in writing, figuring, &c. Because in all cases, if what be drawn with it be not right, or does not please, it may be very easily rubbed out with a piece of crumb bread, and the whole redrawn.

V. Of the parallel ruler. The parallel ruler is so called, because as it consists of two straight rules, connected together by two brass bars, yet so as to admit a very free motion to each: the one rule must always move parallel-wise to the other, that is, one rule will be every where equidistant from the other, and by this means it draws accurately parallel to one or more lines parallel to, or equally distant from, any line proposed. The manner of doing which is thus:

Let it be required to draw a straight line parallel to a given line A B, and at the dis-

tance AC, from it. (fig. 5.) First open the rules to a greater distance than A C, and place the edge of the ruler exactly on the line A B; then, drawing the other rule (fig. 6) firmly on the paper, you move the upper line down from A to the point C, by which (holding it fast) you draw the line C D, which will be parallel to the given line A B.

Many very useful problems in the mathematics are performed by this instrument, of which the following are examples.

1. Let it be required to find a fourth proportional to three right lines given, A B, B C, and A D (fig. 6). To do this, draw the lines A C, A E, marking any angle at pleasure. Upon A C with the compasses set off the lines A B and B C; and upon A E set off the line A D; join D B, and parallel to it draw E C, then will D E be the fourth proportional required. For A B : B C : : A D : D E.

Again, suppose it required to divide any line, say A B, into line A B, and D/E (fig. 7). To do this, join the extremities of each line A B, and parallel to it draw E F, through the given points D E F in the line A C; and by these lines the line A B will be divided exactly similar to the line A C.

The parallel ruler is seldom put into a case of instruments, but those of the larger and better sort; being generally sold by itself, in various sizes, from 6 inches to 2 feet in length.

To the plain scale. The lines generally drawn on the plain scale are these following:

<table>

Of the lines of equal parts. Lines of equal parts are of two sorts, viz. simply divided, and diagonally divided, Plate 3.

1. Simply divided, there are three parallel to one another, at unequal distances (fig. 8), and of any convenient length; divide this length into what number of equal parts is thought necessary, allowing some certain number of these parts so much, as 2, 3, 4, 5, &c., which divisions distinguish by lines drawn across the three parallels. Divide the left-hand division into 10 equal parts, which distinguish by lines drawn across the other parallels but for distinction’s sake, let the fifth division be somewhat longer than the others; and it may not be inconvenient to divide the same left hand division equal parts, which, when laid down on the upper parallel line, having the third, sixth, and ninth divisions distinguished by longer strokes than the rest, whereas that at the sixth division make the longest.

There are, for the most part, several of these simply divided scales put on rulers, one above the other, with numbers on the left hand, shewing in each scale, how many equal parts an inch is divided into; such as 20, 25, 30, 35, 40, 45, &c. and are servedly used, as the plan to be expressed should be larger or smaller.

The use of these lines of equal parts, is to lay down any line expressed by a number of two places or denominations, whether decimally or duodecimally divided; as leagues, miles, chains, poles, yards, feet, inches, &c., to the number of parts, one with each part; thus, if each of the divisions be reckoned 1, as 1 league, mile, chain, &c. then each of the subdivisions will express the part thereof; and if each of the large divisions be called 10, then each small one will be 1; and if the large divisions be 100, then each small one will be 10, &c.

Therefore to lay off a line 8, or 87, or 870 parts, let them be leagues, miles, chains, &c. set one point of the compasses on the ist part of the large divisions, counting from the left hand towards the right, and open the compasses, till the other point falls on the 7th of the small divisions, counting from the right hand towards the left, then are the points of the line of 8, or 87, or 870 leagues, miles, chains, &c. and bears such proportion in the plan, as the line measured does to the thing represented.

But if a length of feet and inches was to be expressed, the same large divisions may represent the feet, and the rest of the inches may be taken from the compasses, as 7 or 87 or 870 leagues, miles, chains, &c. and the like is to be understood of any other dimensions.

2. Diagonally divided. Draw eleven lines parallel to each other, and at equal distances; divide the upper of these lines into such a number of equal parts, as the scale to be expressed is intended to contain; and from each of these divisions draw perpendiculars through the eleven parallels (fig. 9); then the lines from the first of these divisions into 10 equal parts, both in the upper and lower lines; then each of these subdivisions may be also subdivided into ten equal parts, by drawing diagonal lines; viz. from the 10th below, to the ninth above; from the ninth below to the eight above; from the eighth below to the seventh above, &c. till from the first below to the 0th above, so that by these means one of the primary divisions on the scale will be divided into 100 equal parts.

There are generally two diagonal scales laid on the same plane or face of the ruler, one being commonly half the other (fig. 9); the use of the divided scale is much the same with the simple scale; all the difference is, that a plan may be laid down more accurately by it; because in this, a line may be taken of three denominations, whereas from the former, only one could be taken.

Now from this construction it is plain, if each of the primary divisions represent 1, each of the first subdivisions will express $\frac{1}{10}$ of 1; and each of the second subdivisions (which are taken on the diagonal lines, counting from the top downwards) will express $\frac{7}{10}$ of
the former subdivisions or a 100th of the primary divisions; and if each of the primary divisions express 10, then each of the first subdivisions will express 1, and each of the 2d, 1/10; and if each of the primary divisions represent 100, then each of the first subdivisions will be 1, and each of the 2d will be 1, &c., D.

Therefore to lay down a line, whose length is expressed by $347\times 37\frac{a}{7}$ or $3\times 7\frac{a}{7}$ wheaters, miles, chains, &c.

On the diagonal line, joined to the 4th of the first subdivisions, count 7 downwards, reckoning the distance of each parallel 1; there set one point of the compasses, and extend the other, till it falls on the intersection of the third primary division with the same parallel in which the other foot rests, and the compasses will then be opened to express a line of $347\times 37\frac{a}{7}$ or $3\times 7\frac{a}{7}$ &c.

Those who have frequent cause to use scales, perhaps will find, that a ruler with the 20 following scales on it, viz. 10 on each face, will suit more purposes than any set of simply divided scales hitherto made public, on one rule.

One side.—The divisions to an inch. 10, 71, 14, 185/4, 15, 165, 18, 20, 22, 25.

Other side—The divisions to an inch. 23, 32, 36, 40, 45, 50, 56, 60, 70, 85, 100.

The left-hand primary division, to be divided into 10 and 15 parts; for these subdivisions are of great use in drawing the parts of a fortress, and of a piece of cannon.

It will here be convenient to shew, how any plan expressed by right lines and angles, may be delineated by the scales of equal parts, and the protractor. Suppose three adjacent things, in any right-lined triangle being given, to form the plan thereof.

**Example.** Let ABC (fig. 10) be a triangular field, the side $\angle B = 327$ yards; $AC = 208$ yards; and the angle at $A = 44\frac{a}{4}$ degrees.

**Construction.** Draw a line AB at pleasure; then from the diagonal scale take 327 between the points of the compasses, and lay it from A to B; set the centre of the protractor to the point A, lay off 44\frac{b}{4} degrees, and by that mark draw AC; take with the compasses from the same scale 208, lay it from A to C, and join C B; so shall the parts of the triangle ABC, in the plan, bear the same proportion to each other, as the real parts in the field do.

The side C B may be measured on the same scale from which the sides A B, A C, are taken; and the angles at B and C may be measured by applying the protractor to them.

If two angles and the side contained between them were given.

Draw a line to express the side (as before); at the ends of that line, point off the angles; as observed in the field; lines drawn from the ends of the given line through those marks, shall form a triangle similar to that of the field.

Five adjacent things, sides and angles, in a right-lined quadrilateral, being given, to lay down the plan thereof, fig. 11.

**Example.** Given $\angle A = 70^\circ$; $AB = 295$ links; $\angle B = 115^\circ$; $BC = 599$ links; $\angle C = 115^\circ$.

Vol. II.

**INSTRUMENTS.**

**Construction.** Draw A D at pleasure; from A draw A B, so as to make with A D an angle of 120°; make $AB = 215$ (as above the scales); from B, draw BC, to make with $AB$ an angle of 115°; make $BC = 599$; from C, draw CD, to make with $CB$ an angle of 115°; and by the intersection of $CD$ with $AD$, a quadrilateral will be formed similar to the figure in which such measures could be taken as are expressed in the example.

If three of the things were sides, the plan might be formed with equal ease.

Following the same method, a figure of many more sides may be delineated; and in this manner, or some other like to it, surveyors make their plans or surveys.

The remaining lines of the plain scale are thus constructed.

Describe a circumference with any convenient radius, and draw the diameters fig. 12 A B, D E; make $A D$, $B E$, right angles to each other; continue $BA$ at pleasure towards F; through D, draw D G parallel to $BF$; and draw the chords B D, B E, A D, A E. Circumscribe the circle with the chords $BH$, whose sides H M, M N, shall be parallel to A B, B D.

1. **To construct the line of chords.** Divide the arc A D into 90 equal parts: mark the 10th divisions with the figures 10, 20, 30, 40, 50, 60, 70, 80, 90; on D, as a centre, take the divisions of the quadrant arc, to the chord A D, which marked with the figures corresponding, will become a line of chords.

Note. In the construction of this, and the following scales, only the primary divisions are drawn; the intermediate ones are omitted, that the figure may not appear too much crowded.

2. **The line of rhumbs.** Divide the arc B E into 8 equal parts, which mark with the figures 1, 2, 3, 4, 5, 6, 7, 8, and divide each of those parts in right angles to each other; continue $BA$, as a centre, transfer the divisions of the arc to the chord B E, which marked with the corresponding figures, will be a line of rhumbs.

3. **The line of sines.** Through each of the divisions of the arc A D, draw right lines parallel to the radius $AC$; and C D will be divided into a line of sines which are to be numbered from C to D for the right sines, and from D to C for the versed sines. The versed sines may be continued to 180 degrees by laying the divisions of the radius C D, from C to E.

4. **The line of tangents.** A ruler on A, and the several divisions of the arc A D, will intersect the line D G, which will become a line of tangents, and is to be figured from D to G, with 10, 20, 30, 40, &c.

5. **The line of secants.** The distances from the centre C to the divisions on the line of tangents being transferred to the line C F from the centre C, will give the divisions of the line of secants, which must be numbered from A towards F, with 10, 20, 30, 40, &c.

6. **The line of half-tangents (or the tangents of half the arcs).** A ruler on E, and the several divisions of the arc A D, will intersect the radius C A, in the divisions of the semi or half tangents; mark these with the corresponding figures of the arc A D.

The semitangents on the plane scales are generally continued as far as they can be laid out; but the divisions beyond 90° are found by dividing the arc A E like the arc A D, then laying a ruler by E, and these divisions of the arc A E, the divisions of the semitangents above 90 degrees will be obtained on the line C A continued.

7. **The line of longitude.** Divide A H into 60 equal parts; through each of these divisions, parallels to the radius A C, will intersect the arc A E, in as many points; from E as a centre, the divisions of the arc A E, being transferred to the chord A E, will give the divisions of the line of longitude.

The points thus found on the quadrantal arc, taken from A to E, belong to the sides of the equally increasing seamanary parts of the radius; and those arcs reckoned from E, belong to the cosines of those seamanary parts.

8. **The line of latitude.** A ruler on A, and the several divisions of the sines of C D, will intersect the arc A B, in as many points; on B as a centre, transfer the intersections of the arc A B, to the right line B D; number the divisions from B to D, with 10, 20, 30, &c. to 90; and B D will be a line of latitude.

9. **The line of hours.** Bisect the quadrantal arc A B; D, E; in a, b; divide the quadrantal arc a b into 6 equal parts (which gives 15 degrees for each hour); and each of these into 4 others (which will give the quarters). A ruler on C, and the several divisions of the arc a b, will intersect the line M N in the hour, &c. points, which are to be marked as in the figure.

10. **The line of inclinations of meridians.** Bisect the arc A E in c; divide the quadrantal arc a c into 90 equal parts; lay a ruler on C and the several divisions of the arc a c, and the intersections of the line C M will be the divisions of a line of inclinations of meridians.

**Of the sector.** A sector is a figure formed by two radii of a circle, and that part of the circumference comprehended between the two radii.

The instrument called a sector, consists of two flat rulers moveable round on an axis or joint; and from the centre of this joint several scales are drawn on the faces of the rulers.

The two rulers are called legs, and represent the radii of a circle; and the middle of the joint expresses the centre.

The scales generally put on sectors, may be distinguished into single, and double.

The single scales are such as are commonly put on plain scales, and from whence distances or distances are taken, as have been already directed.

The double scales are those which proceed from the centre; each scale is laid twice on the same face of the instrument, viz. once on each leg: from these, distances are to be taken, when the legs of the instrument are in an angular position, as will be shewn hereafter.
The scales of lines, chords, sines, tangents, rhumbs, latitudes, hours, longitude, incl. merid. may be used, whether the instrument is shut or open, each of these scales being contained on one of the legs only.

The scales of inches, decimals, logarithms, sines, tangents, rhumbs, latitudes, hours, longitude, inclin. Merid. are used for similar rules, and are to be used with the sector quite opened, part of each scale lying on both legs.

The double scale of lines, chords, sines, and tangents, or that of which the radius is a degree, are all of the same radius or length; they begin at the centre of the instrument, and are terminated near the other extremity of each leg; viz. the lines at the division 10, the chords at 60, the sines at 90, and the tangents at 45; the remainder of the tangents, or those above 45 degrees, are on other scales beginning at 4 of the length of the former, counted from the centre, where they are marked with 45, and run to about 75°.

Each double scale, one being on each leg and proceeding from the centre, makes an angle; and in an equal angular position are all the double scales, whether of lines, or of chords, or of sines, or of tangents to 45 degrees.

And the angles made by the scales of upper tangents, and of secants, are also equal; and sometimes these angles are made equal to those made by the other double scales.

The scales of polygons are put near the inner edge of the legs: their beginning is not so far removed from the centre, as the 60 on the chords is: where these scales begin, they are marked with 4, and from thence are figured backwards, or towards the centre, to 12.

From this disposition of the double scales, it is plain, that those angles which were equal to each other, while the legs of the sector were close, will still continue to be equal, although the sector be opened to any distance it may admit.

We shall now illustrate the nature of this instrument by examples.

Let CL, CL, (fig. 13) be the two lines of lines upon the sector, opened to an angle LCL; join the divisions 4 and 4, 7 and 7, 10 and 10, by the dotted lines a, b, c, d, E L. L. Then by the nature of similar triangles, it is C L to C B, as L L to a b; and C L to C d, as L L to e d; and therefore a b is the same part of L L as C B is of C d. Consequently, if L L be 10, then a b will be 4, and c d will be 7 of the same parts.

And hence, though the lateral scale C L be fixed, yet a parallel scale L L, is obtainable at pleasure; and therefore though the lateral radius is of a determined length in the lines of chords, sines, tangents, and secants, yet the parallel radius may be had of any size you want, by means of the sector, as far as its length will admit; and all the parallel sines & c. peculiar to it, as will be evident by the following examples in each pair of lines.

Ex. 1. In the lines of equal parts. Having 3 numbers given, 4, 7, 10, to find out a 4th proportional. To do this, take the lateral extent of 16 in the line C L, and apply it parallel-wise, from 4 to 4, by a proper opening of the sector; then take the parallel distance from 7 to 2 in your compasses, and on applying one foot in C, the other will fall on 28 in the line of lines C L, and is the number required; for 4: 7: 16 = 28.

Ex. 2. In the lines of chords. Suppose AB required to lay off an arc of a circle, equal to 33 degrees; then with any convenient opening of the sector, take the extent from 60 to 60, and with it (as radius) on the point C describe the arch A D indefinitely; then in the same opening of the sector take the parallel distance from 33 degrees to 33 degrees, and set it from A to B in the arch A D and draw A B, and it makes the angle at C required.

Ex. 3. In the lines of sines. The lines of sines, tangents, and secants, are used in conjunction with the lines of lines in the solution of all the cases of plain trigonometry; thus let there be given in the triangle A B C, (fig. 14) the side A B = 230°, and the angle A B C = 36° 30'; to find the side A C. Here the angle at C is 53° 30'. Then take the lateral distance 230, from the line of lines, and make it a parallel from 53° 30' to 53° 30' in the line of sines; then the parallel distance between 53° 30' in the same lines, will reach laterally from the centre to 170, 19 in the line of lines for the side A C required.
extent between the first and second terms, you place one foot of the compasses on the third term, then turning the compasses about, the other foot will fall on the fourth term sought.

Thus in example 1, of the three given numbers 4, 7, and 10, if you take the extent from 4 to 7 in the compasses, and place one foot in 10, the other will fall on 28 as the answer, in the line of numbers marked a.

Again, the artificial lines of numbers and sines are used together in plain trigonometry, as in example 3, where the two angles David and the side given; for here, if you take the extent of the two angles 35° 30' and 30° 30' in the line of sines marked a, then placing one foot upon 230 in the line of numbers a, the other will reach to 170 10, the answer.

Also the lines of numbers and tangents are used conjointly, as in the example 4, for take in the line of tangents t, the extent from 45° (radius) to 30° 30', that will reach from 230 17 5 to 176, the answer.

Lastly, the artificial lines of sines and tangents are used together in the analogies of spherical triangles.

This example 6 is solved by taking in the line of numbers, the distance from 60 to 90° (radius) to 30° 15', then that in the line of tangents, will reach from 42° 34' to 28° 30', the answer required.

We shall only further observe that each pair of seventh lines contain the same angle, viz. 6 degrees in the common G-inch sector; therefore to open these lines to any given angle, as 35° for instance, you have only to take 35° literally from the line of chords, and apply it parallelly, from 60 to 60, then will the sides or edges of the sector contain the same angle of 35 degrees.

Of proportional compasses. Though this sort of compasses does not pertain to a common case of instruments, yet a short account of their nature and use may not be unacceptable to those who are not acquainted with them. They are made of two parts, sides of brass, which lie upon each other, so near as to appear one when they are shut.

These sides easily open, and move about a centre, which is itself moveable in a hollow canal cut through the greatest part of their length. To this centre on each side is affixed a sliding piece of a small length, with a fine line drawn on it serving as an index, to be set against other lines or divisions placed upon the compasses. These lines are:
1. A line of lines.
2. A line of superficies, areas, or plans.
3. A line of solids.
4. A line of circles, or rather of polygons to be inscribed in circles.

These lines are all unequally divided, the three first from 1 to 10, the last from 6 to 20; their uses are as follow:

By the line of lines you divide a given line into any number of equal parts; for by placing the index against 1, and screwing it fast, if you open the compasses, then the distance between the points at each end will be equal. If you place the index against 2, and open the compasses, the distance between the points of the longer legs will be twice the distance between the shorter ones; and thus a line is bisected, or divided into an infinite number of equal parts.

If the index be placed against 3, and the compasses opened, the distances between the points will be as 3 to 1, and so a line is divided into three equal parts; and so you proceed for any other number of parts under the compasses.

The numbers of the line of plans answer to the squares of those in the line of lines; for because superficies or plans are to each other, as the squares of their like sides, therefore the square of the plan of 2 is the line of plans; then the distance between the small points will be the side of a plan whose area is 1; but the distance of the larger points will be the like side of a plan whose area is 2, or twice as big. If the index be placed at 3, and the compasses opened, the distances between the points at each end will be the like sides of plans, whose areas are 1 to 3, and so of others.

The numbers of the line of solids answer to the cubes of those in the line of lines; because all solids are to each other as the cubes of their like sides or diameters; therefore, if the index be placed to No. 2, 3, 4, &c. in the line of solids, the lesser and larger points will be the like sides of solids, which are to each other as 1 to 2, 1 to 3, 1 to 4, &c. For example, if the index be placed at 10, and the compasses be opened, the distance will be the diameter of a bullet weighing 1 ounce, then the distance between the larger points will be the diameter of a bullet or globe of 10 ounces, or which is 10 times as big.

Lastly the numbers in the line of circles are the sides of polygons to be inscribed in a given circle, or by which a circle may be divided into those equal parts from 6 to 20.

Thus if the index be placed at 6, the points of the compasses at either end, when opened to the radius of a given circle, will contain the side of a hexagon, or divide the circle into 6 equal parts. If the index be placed against 7, and the compasses opened, so that the index is placed against the radius of the circle; then the shorter points will divide the circle into 7 equal parts for inscribing a heptagon. Again, placing the index to 8, and opening the compasses, the larger points will contain the radius, and the lesser points divide the circle into 8 equal parts, for inscribing an octagon or square. And thus you proceed for others.

Instruments, surgeon's. A case of pocket instruments for surgeons, which they ought always to carry about with them, contains lancets of different sizes; scissors fit for several uses; forceps, plain and furnished with teeth; incision-knives, straight and crooked; a spatula, probes, needles, &c. See Surgery.

Insurance, laws of. Insurance is regarded by the law as a contract between two or more parties; that on one paying a certain premium he shall be indemnified or insured against certain risks set forth in the policy. This is extremely convenient in commerce, but was made use of as a kind of gambling till the statute 14 Geo. III. c. 48, that no insurance shall be made on lives, or on any other event, wherein the parties concerned has no interest; that in all policies the name of such interested party shall be inserted, and nothing more shall be recovered thereon than the amount of the interest of the insured. This, however, does not extend to marine insurances. But as it was a common practice to take in large sums without possessing property on board, and which were called policies or insurances, interest or no interest, and of insuring the same goods several times over, it was enacted, that all insurances, interest or no interest, or without further proof of the interest than the policy, or by way of gaming, or without benefit of salvage to the insurer, should be void, except on privates, or on ships or goods from the Spanish or the enemy; and this was confirmed by the courts; and that no re-assurance shall be legal, unless the former insurer be insolvent or dead; and that in the East India trade the lender of money on bond, or at responderia, shall alone have a right to be indemnified for the money lent; and the borrower shall receive no indemnification or satisfaction from the surplus of his bottomry or responderia bond. No insurance can be made on any illegal voyage.

It is generally calculated in policies that the insurer shall not be answerable for any partial loss on certain articles, but on others less difficult to be preserved at sea, but liable to partial injuries, shall be liable for any partial loss, to the extent of the insured value. Thus, if the ship has been fired at, and all the cargo burned, the insurer shall be liable for those losses above three per cent. But he is liable on all losses, however small, called general average or losses occasioned by the ship's stranding; but this loss must be an immediate, not a remote, consequence of the stranding.

The commencement of the risk on the ship varies in most cases, and usually continues till the ship has been laid under her former anchor. Upon goods it commences when they are on board, and continues till they are removed or landed. The ship insured must be sound, and in every respect fit to bear the sea, and perform the voyage, and if the đevises from the usual course, and stops at places not usually stopped at, without a proper cause, the contract is void.

Insurance upon life is a contract by which the insurer, for a certain time, granted to the age, health, and profession of the person whose life is to be insured, engages that the person shall not die within a certain period, or if he do, the underwriter will pay a sum agreed upon to the person to whom the policy is granted.

Insurance against fire. The insurer undertakes, in consideration of a premium, to indemnify the insured against all losses by fire which he may sustain in his house or goods during the time mentioned in the policy.

Intaglio, precious stones on which are engraved the heads of great men, inscriptions, and the like; such as we frequently see set in rings, seals, &c.

INTEGER, in arithmetic, a whole number, in contradistinction to a fraction.

Intercalary, in chronology. See Dissextile, &c.

Intercommunion, in law, when the consuls of two towns are held together, and the inhabitants of both have, time out of mind, caused their cattle to feed promiscuously on them.

Intercostal. See Anatomy.

Interdict. See Censorship.
by which the church of Rome forbids the performance of divine service in a kingdom, province, town, &c. This measure has been frequently executed in France, Italy, and Germany; and in the year 1770 pope Alexander III. put all England under an interdict, forbidding all ordination or part of divine service, except bishops of dissenting confessions, and giving abolution to dying penitents.

In 1751, a sum of money, paid or allowed in the loan of some other sum, lent for a certain time, according to some fixed rate or proportion. The sum lent, and on which the interest is reckoned, is called the principal; and in any case where the interest is also to be paid on the same, the principal, a proportionately greater interest is usually paid. The current rate of interest is generally considered as the barometer of public credit; and its lowness is a sign almost intangible of the floorine condition of a state; it proves the increase of industry, and the free circulation of wealth, little inferior to a demonstration. In order to prevent individuals from taking unjust advantage, and from the necessities of other states, certain fixed rates have been found necessary in most countries to establish by law a fixed rate of interest for the use of money; this however must, in a great measure, depend on the current rate of interest prevailing; for if it is attempted to reduce by law the common rate of interest below the lowest ordinary market rate, the restriction will be sure to be evaded. This was the case in France, in 1760, when, although the legal rate of interest was reduced from five to four per cent, money continued to be lent at five per cent.

The first act of parliament for regulating the rate of interest in England was 37 Hen. VIII. c. 9, by which interest was fixed at 10 per cent.; before that time interest had usually been taken at higher rates. In 1552 an act was passed against usury, or taking any interest whatever for money lent; the impolicy and oppression of this measure soon became evident; and in 1571 the statute of Henry VIII. which fixed interest at 10 per cent., was revised. As the increase of the sum lent brought within the country, the rate of interest lowered; and in 1695 it was, by 21 James I. c. 17, reduced to eight per cent. The first positive law made in Scotland for fixing the rate of interest was in 1557, when an act was passed, by which the rate of interest was not for the future to exceed 10 per cent. In France, in 1601, Henry IV. issued an edict for reducing the public or national interest of money in that kingdom to six and a quarter per cent. In 1651 the interest of money in several parts beyond sea being lower than the legal interest in England, the Rump-parliament reduced the legal rate from eight to six per cent; and upon the Restoration it was confirmed by 12 Cha. II. c. 13. The last act of parliament for regulating the interest of money was 12 Ann. st. 2, c. 16, by which it was fixed at five per cent. per annum, the present legal rate; but although this is the utmost interest which can be taken for money lent in Great Britain, yet if a contract which carries interest which was made in a foreign country, our courts will direct the payment of interest according to the laws of the country in which the contract was made: thus American, Turkish, and Indian interest have been allowed, to the amount of even 12 per cent.

The rates which have been paid in Great Britain at different periods, for the current interest for money, are as follows:

In the United States of America, the lawful interest of money is 6 per cent. in most of the States; in a few it is 7 per cent.; in one it is 5 per cent. In Greece, the mean rate of interest is 10 per cent., and in other parts of Turkey nearly the same; in Persia 25 per cent.; and in the Mogul Empire 30 per cent. In these countries there is no fixed rate of interest, and the usual rate rests chiefly on the necessity of lending. In Sydney and the other English settlements in New South Wales, the rate of interest is fixed by an ordinance, dated 13th June, 1804; at 5 per cent, per annum.

Interest is distinguished into Simple Interest and Compound Interest.

**Interest, Simple,** is that which is reckoned on the principal only, at a certain rate for a year, and at a proportionately greater or less sum for a greater or less time; thus, if 50, is the rate of interest of 100 for a year, the interest for two years, 150, for three years, &c. In most computations, the interest the work is much shortened if the interest of 100 for a given term is known, as the interest of any other sum for the same term will then be found by only multiplying by the given sum. The interest of 100 for a year must be the same proportion as the interest of 100 to its principal; therefore, at 5 per cent., as 100 : 5 : 115 : 0.55; and thus:

The interest of One Pound for One Year,

As tables of Simple Interest are chiefly referred to, in order to find the interest or discount on bills of exchange, and as by far the greater number of bills which are discounted have been made at 6, the following table will answer most useful purposes; but those who have constant occasion to make such computations, will find much assistance from the extensive tables which have been computed by Smart, Thomson, King, Reid, and others. See also Discount.

The interest of any sum for any number of days contained in the table, is found by only multiplying the figures corresponding with the number of days by the sum of money, and if the interest of 120. for 61 days is required, the interest of one pound for 61 days, is, by the table, 0.008361, which multiplied by 120, gives 10, 0.48. If the given sum of money is divided and piece, they must be reduced to the decumal of a pound.
The interest for any greater number of days than are contained in the table, is easily found by means of $\frac{x}{y}$; by which it is required to find the interest of 100, for 135 days, the interest for 100 days by the table is 15838, and for 65 days 39011, which two sums added together, make 59329, or 2005, which multiplied by 30, gives 1484574, or 1483.174 d.

The year number of which in which a given sum will increase to another given sum in consequence of being improved at interest, is found by dividing the latter sum by the former, and in the sum table which is nearest to the quotient will show the term required.

Example. In what time will 1001 increase to 2001, if improved at 5 per cent.?

Divide 2001 by 100, and the number in the table nearest to 5 will the quotient, is 5000 in 8 years, which shows that 50 years is the answer.

</table>
INTERJECTION, in grammar, an indeclinable part of speech, signifying some passion or emotion of the mind.

INTERLOCUTORY ORDER, in law, an order that does not decide the cause, but only some matter incident to it, which happens between the beginning and end of a cause; as when, in chancery or exchequer, the plaintiff obtains an order for an injunction until the hearing of the cause; which order, not being final, is called interlocutory.

INTERMITTENT, or INTERMITTING FEVERS. See Medicine.

INTERNAL, in general, signifies whatever is within a thing.

Euclid proves that the sum of the three internal angles of every triangle is equal to two right angles; whence he deduces several useful corollaries. He likewise adduces, from the same proposition, this theorem, viz., that the sum of the angles of every rectilinear figure, is equal to twice as many right angles, as the figure hath sides, each side subtracting four.

INTERROGATORIES, are questions exhibited in writing to be asked witnesses or contemporaries to be examined. Those interrogatories are in the nature of a charge or accusation; and if any of them is improper, the defendant may refuse to answer it, and move the court to have it struck out. Str. 444.

INTERSECTION, in the mathematics, signifies the cutting of one line or plane by another: thus we say, that the mutual intersection of two planes is a right line.

INTERVAL, in music, the difference in point of gravity or acuteness between any two sounds. Taking the word in its more general sense, we must allow that the possible intervals of sound are infinite, but we only speak of those intervals which exist between the different tones of any established system. These are divisible into simple, compound, or composite, which they call diatonic, and composite intervals, which they call systems. The least of all the intervals in the Greek music was, according to Iamblicus, the difference of one or fourth of a tone; but our scale does not notice so small a division, since all our tones concur in consonances, to which order only one of the three ancient genera, viz., the diatonic, was accommodated. Modern musicians consider the semitone as a simple interval, and only call those compound which consist of two or more semitones; thus from B to C is a semitone, or simple interval, but from C to D is two half-tones, or a compound interval.

TESTATES. There are two kinds of intestates; one that makes no will at all; and another that makes a will, and nominares executors, but they refuse; in which case he dies intestate, and the ordinary commits ad interim a Pet. Inst. 307.

The ordinary by special acts of parliament is required to grant administration of the effects of the deceased to the widow or next of kin, who shall first pay the debts of the deceased, and then distribute the surplus among the kindred, in the manner and according to the proportions directed by 22 and 33 Car. II. c. 10.

INTESTINA, in natural history, an order of worms. The individuals of this order are of a formation the most simple, and live some of them within other animals, some in waters, and a few in the earth. The Gordius perforates clay to give a passage to springs and water, the limerius pierces the earth, that it may be exposed to the action of the air and moisture: in like manner the teredo penetrates wood; and the pilosus and mytilus rocks, and their dissolution.

INTESTINES. See Anatomy, and Physiology.

INTRUSION, in law, is when the ancestor dies seised of any estate of inheritance, expectant upon an estate for life; and then the tenant for life dies, between whose death, and the entry of the heir, a stranger intrudes.

INVESTED, in heraldry, denotes a thing fluted or furrowed. See Heraldry.

INVENTION. See Painting.

INTEREST, in law, is the giving possession of lands by the seisin. The ancient feudal investiture, in which the vassal on descent of land was admitted into the lord's court, and there received his seisin, in the nature of a renewal of his ancestor's grant, in the presence of all the rest of the tenants; but in after-times, entering on any part of the lands, or other notorious possession, was admitted to be equivalent to the formal grant of seisin and investiture: 2 Black. 269.

The manner of grant was by words of pure donation, or given and granted: which are still the operative words in our modern indentations or deeds of feoffment. This was perfected by the ceremony of corporal investiture, or open and notorious delivery of possession in the presence of the other vassals.

But a corporal investiture being sometimes inconvenient, a symbolic delivery of possession was in many cases usually allowed of; by transferring something near at hand, in the presence of credible witnesses, which by agreement should serve to represent the very thing designed to be conveyed; and an occupancy existing, the symbol was permitted as equivalent to the occupancy of the land itself. And to this day, the conveyance of many of our copyhold estates is made from the seller to the lord, or his steward, by delivering a rod or verge, and then from the lord to the purchaser, by a re-delivery of the same, in the presence of a jury of tenants. 2 Black. 313.

INULA, fleabane, a genus of the syngenes polygony-auperillus class of plants, with radiated flowers; the receptacle is naked; the down is simple; and the anther is terminated in five at their bases. There are thirty-four species, of no note.

INVOICE, an account in writing of the particulars of that which is shipped off the goods, to be dispatched by post, or otherwise, to the correspondent. This copy is commonly drawn out upon a sheet of large post-paper, to the end of which is subjoined a letter of advice,

INVOLEMENT. See Botany.

INVOLUTION. See Algebra.

JOINT ACTIONS: in personal actions, several groups may be joined in one suit; but actions found on the same cause of action and a contract cannot be joined, for they may require different pleas and different process. 1 Vent. 333.

JOINT and SEVERAL: an interest cannot be granted jointly and severally; as if a man grants his property to his heir and a servant for life, he cannot make a lease for years, to two jointly and severally; these words (severally) are void, and they are joint tenants. 5 R. 19.

JOINT LIVES: lease for years to husband and wife, if they or any issue of their bodies should so long live as the parties, or the one of them should survive, the other; and not only so long as the husband and wife, &c. should jointly live. Nos. 599.

JOINT TENANTS, are those that come to, and hold and possess the estate by one title pro indiviso, or without partition.

These are distinguished from sole or several tenants, from parceners, and from tenants in common: and they must jointly infeoff, and jointly be implied, and partly and the like of them, and co-parceners; but joint tenants have a sole quality of survivorship, which coparceners have not; for there are two or three joint tenants, and one has issue and dies, then he or those joint tenants that survive, shall have the whole by survivorship. Cowd.

The creation of an estate in joint tenancy depends on the wording of the deed or devise, by which the tenant claims title; for this estate can only arise by purchase or grant, that is, by the act of one person, and never by the mere act of law. Now if any estate is given to a plurality of persons, without adding any restrictive, exclusive, or explanatory words, as if an estate is granted to A and B and their heirs, this makes them immediately joint tenants in fee of the land; for the law interprets the grant, so as to make all parts of it take effect, which can only be done by giving both parties the same estate in them both. Therefore the grantor in the preceding pleased their names, the law gives them a thorough union in all other respects. 2 Black. 150.

If there are two joint tenants, and one releases the other, this passes a fee without the word heirs, because it refers to the whole fee, which they jointly took and are possessed of by force of the first conveyance; but the tenants in common cannot release to each other, for a release supposes the party to have the thing righted, but tenants in common have several distinct estates and interests, which they cannot transfer otherwise than as persons who are sole seized. Co. Litt. 9.

Although joint tenants are seized per me per tout, yet to divers purposes each of them has but a right to a moiety; as to enfeoff, give, or demise, or to forfeit or lose by death in default of a precent; and therefore where there are two or more joint tenants, and they all join in a feoffment, or each of them in joint feoffment gives his appurtenant, Co. Litt. 206.

The right of survivorship, which takes place immediately upon the death of the joint tenant, whether it is a natural or civil death; as if there are two joint tenants, and one of
The estate must be for term of the wife's life, or a greater estate; therefore if an estate is made for life of the X. or many others, this is no good jointure; for if she lives longer than her husband, she may not only to break the provision of life, but also to exclude her from claiming dower, and likewise her settlement, it seems that a provision or settlement on the wife, by way of trust, in other respects it answers the intention of the statute, will be inured in a court of equity.

The estate must be in satisfaction of the whole dower; the reason hereof is, that if it is made in satisfaction of part only, it is uncertain for what part it is in satisfaction of her dower, and therefore void in the whole. Co. Lit. 36.

The estate must be expressed or averred to be in satisfaction of her dower. Lord Coke says, that it must be expressed or averred to be so by a competent provision, and also to this for this does not seem requisite either within the words or intention of the statute. Co. Lit. 36.

It should be made during the coverture; this the very words of the act of parliament require; and therefore if a jointure is made to a woman during her coverture in satisfaction of dower, she may wave it after her husband's death; but if she enters and agrees thereto, she is concluded; for though a woman is not bound by any act when she is not a party to the settlement, yet if she agrees to it when she is at liberty, it is her own act, and she cannot avoid it. Co. Lit. 36. Co. 3.

JOINTURE. A jointure strictly speaking, signifies a joint estate, limited to both husband and wife; but in common acceptation, it extends also to a sole estate, limited to the wife only, and may be thus defined, viz. a competent livelihood of freedom for the wife of lands and tenements, to take effect, in profit or possession, presently after the death of the husband; for the life of the wife at least. 2 Bl. 137.

By the statute of the 97th II. VIII. c. 10, if a jointure is made to the wife, it is a bar of her dower, so that she shall not have both jointure and dower. And to the making of a perfect jointure within that statute six things are observed: 1. Her jointure is to take effect presently after her husband's decease. 2. It must be for the term of her own life, or greater estate. 3. It should be made to herself. 4. It must be in satisfaction of her whole dower, and not of part of her dower. 5. It must either be expressed or averred to be in satisfaction of her dower. 6. It should be made during the coverture. 1 Inst. 32.

The estate must take effect presently after her husband's decease; therefore if an estate is made to the husband for life, remainder to another person for life, remainder to the wife for her jointure, this is no good jointure, for it is not within the words or intent of the statute; for the statute designed nothing as a satisfaction for dower, but that which came in the same place, and is of the same use to the wife; and though the other person dies during the life of the husband, it is not sufficient for every interest not equivalent to dower nor being within the statute, a void limitation to deprive the wife of her dower. 4 Co. 3.
The water disappears. It is then moistened again, and the process repeated till the whole is oxidized. The mass is then pounded, and the powder heated in an iron vessel till it is perfectly dry, stirring it constantly. By making steam pass through a red-hot iron tube, the iron is changed into a brilliant black brittle substance, which, when pounded, assumes the appearance of martial etchings.

This experiment is also made by Lavosier.

3. By burning iron wire in oxygen gas. The wire as it burns is melted, and falls in drops to the bottom of the vessel, which ought to be covered with very fine copper. These metallic drops are brittle, very hard, and blackish, but retain the metallic lustre.

They were examined by Lavosier, and found precisely the same with martial etchings.

The oxide so formed is always composed of 73 parts of iron and 27 of oxygen, as Lavosier and Proust have demonstrated.

It is attracted by the magnet, and is often itself magnetic. It is capable of crystallizing, and is often found native in that state.

The peroxide or red oxide of iron may be formed by keeping iron filings red-hot in an open vessel, for a long time.

One oxide is found native in the iron dam, which is formed by the filings in the vessel, and is called the dam oxide.

Consequently the peroxide, when converted into red oxide, absorbs 0.40 of oxygen; and the same thing, the red oxide is composed of 66.5 parts of black oxide and 33.5 parts of oxygen. One hundred parts of iron, when converted into a peroxide, absorbs 37 parts of oxygen, and the oxides are again converted into peroxide, it absorbs 52 additional parts of oxygen, and the oxide weighs 189.

The peroxide cannot be decomposed by heat; but when heated along with its own weight of iron filings, the whole, as Vaupellin first observed, is converted into black oxide.

The reason of this conversion is evident: The 100 parts of peroxide are composed of 52 parts of iron, combined with two different doses of red quicklime. With 14 parts, which, with the iron, make 66 of protoxide: With 34 parts, which, with the protoxide, make up the 100 parts of peroxide. Now, the first of these doses has a much greater affinity for the iron than the second has. Consequently the 34 parts of oxygen, which constitute the second dose, being retained by a weak affinity, are easily abstracted by the 100 parts of peroxide; and combining with the iron, the whole at once is converted into black oxide: for 100 parts of iron, to be converted into black oxide, require only 37 parts of oxygen.

The peroxide of iron is not magnetic. It is converted into black oxide by sulphurated hydrogen gas and many other substances; which deprive it of the second dose of oxygen, for which they have a stronger affinity, though the wire is capable of decomposing the protoxide. Iron is capable of combining with all the simple combustible bodies.

A small mixture of it constitutes that particular kind of iron, known by the name of cast iron, because it is brittle when cold, though it is malleable when hot.

Birman has shown that the brittleness and bad qualities of cold short iron may be removed by heating it strongly with limestone, and with this the experiments of Lavasavey correspond.

There are a great many varieties of iron, which artists distinguish by particular names; but all of them may be reduced under one or other of the following classes: cast iron; wrought or soft iron; and steel.

Cast iron, or pig iron, is the name of the metal when first extracted from its ores.

The ores from which iron is usually obtained are composed of oxide of iron and clay. The object of the manufacturer is to reduce the oxide to the metallic state, and to separate it from the clay. The two objects are accomplished at once by mixing the ore reduced to small pieces with a certain portion of limestone and of charcoal, and subjecting the whole to a very violent action of heat.

The charcoal absorbs the oxygen of the oxides, and leaves the iron in the metallic state; the limestone combines with the clay, and both together run into fluxes, and form a kind of thin glass; the iron is also melted by the violence of the heat, and being heavier than the glass, falls down, and is collected at the bottom of the furnace. Thus the contents of the furnace are separated into two portions; the glass swells at the surface, and the iron rests at the bottom. A hole at the lower part of the furnace is now opened, and the iron is shown how it can be moulded for all purposes of reception.

The cast iron thus produced is distinguished by the following properties: It is scarcely malleable at any temperature. It is generally so hard as to resist the file. It can neither be hardened to a point, nor formed into a cold curve by any means.

Cast iron is converted into wrought iron, by putting it into a furnace, and kept melted, by means of the flame of the combustibles, which is made to play upon its surface. While melted, it is constantly stirred by a workman, that every part of it may be exposed to the air. In about an hour the hottest part of the mass begins to heave and swell, and to emit a lamen- bent blue flame. This continues nearly an hour; and by that time the conversion is completed. The heaving is evidently produced by the emission of the combustible fluid, As the process advances, the iron gradually acquires more consistency; and at last, notwithstanding the continuance of the heat, it
conceals all together. It is then taken while hot, and hammered violently, by means of a heavy hammer, and it is thereupon not only makes the particles of iron approach nearer each other, but drives away several impurities which would otherwise continue attached to the iron.

In this state it is the substance described under the name of iron. As it has not been demonstrated, it is considered at present, when pure, as a simple body; but it has seldom or never been found without some small mixture of foreign substances. These substances are either some of the other metals, or even on, carbon, phosphorus.

When small pieces of iron are stratified in a close crucible, with a sufficient quantity of charcoal-powder, and kept in a strong red heat for eight or ten hours, they are converted into steel, which is distinguished from iron by the following properties:

It is so hard as to be unannulable while cold; or at least it acquires this property by being immersed while ignited into a cold liquid; for this immersion, though it has no effect upon iron, adds greatly to the hardness of steel.

It is brittle, resists the file, cuts glass, affords spark with flint, and retains the magnetic virtue for any length of time. It loses this hardness by being ignited and cooled very slowly. It melts at above 1300° Westergood.

It is malleable when red-hot, but scarcely so when raised to a white heat. It may be hammered out into much thinner plates than iron. It is more sonorous; and its specific gravity, when hammered, is greater than that of iron.

By being repeatedly heated in an open vessel, and hammered, it becomes wrought iron, which is a simple substance, and if perfectly pure would contain nothing but iron.

Steel is iron combined with a small portion of carbon, and has been for that reason called carburated iron. The proportion of carbon has not been ascertainment with much precision. From the analysis of Vanquelin, it amounts to 0.17%, to 0.40%.

Mr. Clout seems to affirm that it amounts to 0.2% part; but he has not published the experiments which led him to a proportion, which so far exceeds what has been obtained by other chemists.

That steel is composed of iron combined with pure carbon, and not with charcoal, has been demonstrated by Morveau, who formed steel by combining together directly iron and diamond. At the suggestion of Cloutet, he inclosed a diamond in a small crucible of pure iron, and exposed it completely covered up in a common crucible to a sufficient heat.

The diamond disappeared, and the iron was converted into steel. The diamond weighed 907 parts, the iron 57,800, and the steel obtained 56,584; so that 2313 parts of the iron and 15 parts lost in the operation. From this experiment it follows, that steel contains about 0.3% of its weight of carbon.

This experiment was objected to by Mr. Maslett, but the objections were fully refuted by Dr. Gregory and Mr. Cloutet.

Himma, long ago, pointed out a method by which steel may be distinguished from iron. When a little diluted nitric acid is dropped upon a plate of steel, allowed to remain a few minutes, and then washed off, it leaves the spot or a whitish-green. We can easily see the reason of this spot: it is owing to the carbon of the iron which is converted into charcoal by the acid.

This experiment shows us, that carbon is much more readily oxidized when combined with iron than when crystallized in the diamond.

Cast iron, is iron combined with a still greater proportion of carbon than is necessary for forming steel. The quantity has not yet been ascertained with precision: Mr. Clout makes it amount to $\frac{3}{4}$ of the iron. The blackness of the colour, and the fusibility of cast iron, are proportional to the quantity of carbon which it contains. Cast iron is almost always contaminated with foreign ingredients: these are chiefly oxide of iron, phosphur, and silica.

It is easy to see why iron is obtained from its ore in the state of cast iron. The quantity of charcoal, along with which the ore is fused, is so great, that there is an opportunity of saturating itself with it.

The conversion of cast iron into wrought iron is effected by burning away the charcoal, and depriving the iron wholly of oxygen: this is accomplished by heating it violently behind a black spot, whereas the iron has found, that when cast iron is mixed with $\frac{3}{4}$ of its weight of black oxide of iron, and heated violently, it is equally converted into pure iron.

The oxygen of the oxide, and the carbon of the cast iron, combine, and leave the iron in a state of purity.

The conversion of iron into steel is effected by combining it with carbon. This combination is performed in the large way by three different processes, and the products are distinguished by the name of natural steel, steel of cementation, and cast steel.

Natural steel is obtained from the ore by converting it first into cast iron, and then exposing the cast iron to a violent heat in a furnace while its surface is covered with a mass of melted scorie five or six inches deep, Articles of the carbon combines with the oxygen which cast iron always contains, and flies off in the state of carbonic acid gas. The remainder combines with the pure iron, and constitutes it steel. This steel is inferior to the other species; its quality is not the same throughout; it is softer, and not so apt to be k; and as the processes by which it is obtained are less expensive, it is sold at a lower price than the other species.

It is obvious that iron and carbon are capable of combining together in a variety of different proportions. When the carbon exceeds, the compound is carburet of iron, or plumbago. When the iron exceeds, the compound is steel or cast iron in various proportions.

All these compounds may be considered as subcarbonates of iron. The hardness of iron increases with the proportion of charcoal with which it combines, till the carbon amounts to about $\frac{1}{2}$ of the whole mass. The hardness is then a maximum; the metal acquires the colour of silver, loses its granulated appearance, and assumes a crystallized form. If more carbon is added to the compound, the hardness diminishes in proportion to its quantity.

The affinities of iron, and its oxides, are arranged by Herrman as in the following table:

<table>
<thead>

IRON-SICK, in the sea-language, is said of a ship or boat, when her bolts or nails are so eaten with rust, and so worn away, that they occasion hollows in the planks, whereby the vessel is rendered leaky.

IRRATIONAL, an appellation given to surd numbers and quantities. See ALGEBRA.

IRREGULAR, in grammar, such inflections of words as vary from the general rules; thus we say, irregular nouns, irregular verbs.

ISATIS, WOAD; a genus of the silique order, in the tetradynamia class of plants; and in the natural method ranking under the 30th order, the siliqueons. The silique is lanceolated, unicellular, monospemous, bivalved, and deciduous; the valves navicular or canoe-shaped. There are four species; but the only one worthy of notice is the tictoria, or common woad, which is cultivated in several parts of Britain for the purposes of dyeing, being used as a foundation for many of the dark colours. See DYES.

ISCHEMUM, a genus of the monocot order, in the polyagamia class of plants; and in the natural method ranking under the 4th order, gramina. The calyx of the herbophyllum is a bilobous glume; the corolla bivalved; there are three Stamina, two styles, and one seed. The calyx and corolla of the male, as in the former, with three stamina. There are eight species.

ISCHURY. See MEDICINE.

ISERTIA, a genus of the hexandria monogamia class and order; the cal is uncoloured, four or six toothed; cor. six-cleft, funnel-form; pome subglobular, six-celled. There is one species, a tree of Cayenne.

ISINGLASS, in the materia medica, &c. See ACIPENSER.

ISSARDIA, a genus of the monogamia order, in the tetradynamia class of plants; and in the natural method ranking under the 17th order, calycanthem. There is no corolla; the calyx is quadrifid; the capsule quadrifidular, and girl with the calyx. There is one species, the aquatic and annual.

ISOCHELÉ TRIANGLE, in geometry, one that has two equal sides.

ISOCRHONAL, ISOCRONE, or IS-
CHRONICUS, is applied to such vibrations of a pendulum, as are performed in the same space of time; as all the vibrations or swings of the same pendulum are, whether the arches it describes are longer or shorter: for when it is describes a shorter arch, it moves so much the slower, and when a long one proportionally faster.

BICHORAL lines, that in which a heavy body is supposed to descend without any acceleration.

ISOETES, a genus of the natural order of filifers, belonging to the cryptogamia class of plants. The anther of the male flower are within the base of the frond or leaf. The capsule of the female flower is baccate, and within the base of the leaf. There are two species.

ISOMETRICAL Figures, in geometry, are such as have equal perimeters, or circumferences.

1. Of isometrical figures, that is the greatest that contains the greatest number of sides, or the most angles, and consequently a circle is the greatest of all figures that have the same compass as it has.

2. Of two isometrical triangles, having the same base, wherein two sides of one are equal, and of the other unequal, that is the greatest whose two sides are equal.

3. Of isometrical figures, whose sides are equal in number, that is the greatest which is equalateral and equangular. From hence follows that common problem of marking the lodging or wailing that will wall in one acre, or even any determinate number of acres, a, fonce or wall in any greater number of acres what ever b. In order to the solution of this problem, let the greater number b be supposed a square. Let a be one side of an oblong, whose area is a; then will \( \frac{a}{b} \) be the other side; and \( 2a + 2b \) will be the ambit of the oblong, which must be equal to four times the square-root of b; that is, \( 2a + 2b = 4 \sqrt{b} \). Whereas the value of \( x \) may be easily had, and you may make infinite numbers of squares and oblongs that have the same ambit, and yet shall have different given areas, thus.

Let \( \sqrt{b} = d \).

Then, \( \frac{a}{b} = \frac{4d}{a} \).

\( a + 2b = 2d \).

\( 2ax - 2bd = -a \).

\( ax = \frac{2}{d} - \frac{a}{b} \).

\( bx = a \frac{2}{d} + \frac{a}{b} + 2d \).

That, if one side of the square be 10; and one side of an oblong be 10, and the other 1; then with the ambit of that square and oblong be equal, viz. each 40, and yet the area of the square will be 100, and of the oblong but 19.

ISOPHYNUM, in botany; a genus of the polygynous order, in the polyandra class of plants; and in the natural method ranking under the third order, multisepulque. There is no calyx, but five petals; the nectaria triad and tubular; the capsules recurved and polyhymnous. There are two species, of no note.

ISSUE, in law, has several significations, it being sometimes taken for the children begotten between man and his wife; sometimes for profits arising from amercements and fines; and sometimes for the profits issuing out of lands or tenements: but this word generally signifies the conclusion, or point of matter, that is, the question from the allegations and pleas of the plaintiff and defendant in a cause to be tried by a jury or court.

There are two kinds of issues in relation to causes, that upon a matter of fact, and that upon a matter of law: that is of fact is where the defendant has done any such thing as the plaintiff has alleged against him; and special, where some special matter, or material point alleged by the defendant in his defence, is to be tried. General issue and special issue, in which the defendant is allowed to give the special matter in evidence, by way of excuse or justification; this is granted by several statutes, in order to prevent a plaintiff pleading, by allowing the defendant to give any thing in evidence, to prove that the plaintiff had no cause for litigation.

ISSUES on SHERIFFS are such unmerited faces and fines to the crown, as are levied out of the issues and profits of the lands of sheriffs, for their faults and neglect; but these issues, or seeking to a good administrator, or such a thing may be taken off before they are estreated into the exchequer.

ISSUES. SEE SURGERY.

ITEA, a genus of the monogynia order, in the pentandria class of plants; and in the natural method is classed under the 4th order, composite. The male calyx is common and triphylous; the florlets of the disc monopetallous and quinquedent; the receptacle divided by small hairs. There is no female calyx nor corolla, but five fruits in the radius; two long styles; and one naked and obtuse. There are two species, natives of North America.

IVA, a genus of the pentandria order, in the monogynia class of plants; and in the natural method is classed under the 49th order, composito. The male calyx is common and triphylous; the florlets of the disc monopetallous and quinquedent; the receptacle divided by small hairs. There is no female calyx nor corolla, but five fruits in the radius; two long styles; and one naked and obtuse. There are two species, natives of America.

JUDGE. The judges are the chief magistrates in the law, to try civil and criminal causes. Of these there are twelve in England, viz. the lords chief justices of the courts of king's-bench and common-pleas; the lord chief baron of the exchequer; the three puisne or inferior judges of the two former courts; and the three puisne barons of the latter.

By stat. 1 Geo. III. c. 23, the judges are to continue in their offices during their good behaviour, notwithstanding any demise of the crown (which was formerly held immediately to vest in their seats), and their full salaries are absolutely secured to them during the continuance of their commissions, by which means the judges are rendered completely in-
plum with a furrowed kernel. There are 8 species, the most remarkable of which is the regia or common walnut. Other two species, called the nigra and alba, or black and white Virginian walnut, are also cultivated in this country, and are equally proper for fruit, having very small kernels.

JUGULAR. See Anatomy.

JUGULARES, in the Linnaean system, is the name of an order or division of fish, possessing characters which is that they have bony fins. See Fish.

JULES. See Materia Medica.

JULIAN PERIOD. See Chronology.

JULUS, a genus of insects, of the order Aptera. The generic character is, antennae moniliform; tarsi two segmented; body sub-cylindric; legs numerous, twice as many on each side as the segments of the body. The julus are very nearly allied to the scehdrepandars or centipedes, but their body, instead of being flattened, is in those insects, is nearly cylindrical or jointed. They are furnished with two pairs of feet, the number on each side doubling that of the segments, whereas in the scehdrepandars the number of joints and of feet is equal on each side. The male is distinguished by numerous hexagonal coxites, as in the major part of the insect tribe., and the mouth is furnished with a pair of decemtate jaws. These animals, when disturbed, roll themselves up in a flat spiral, their general motion is rather slow and unctuatory. The most common species, the julus sabulosus, is often seen in similar situations with the snail and scehdrepandar, and usually measures about an inch and quarter in length; its colour is a polished brownish black, except the legs, which are paler or whitish: it is an oviparous animal, and the young, when first hatched, are very small, of a whitish colour, and are furnished only with three pairs of legs, which are situated on each side the superior part, or near the heart; the remaining pairs not making their appearance till some days after, when about seven on a side become visible: the nails are black, with a white-red spot on each toe: in this state it may sometimes be found in the soft mould of hollow trees.

JULUS INUS, or great Indian julus, bears an extreme resemblance to the former, but is of a smaller size, and measures only seven inches in length: its colour is similar to that of the preceding species. It is found in the warmer parts of Asia and America, inhabiting woods and other retired places: the number of legs, according to Linnaeus, is a hundred and fifteen on each side, but this seems to be a variable circumstance.

JULUS lagurus, or barbed julus, is a very minute and singular species, not exceeding, when at full growth, the eighth of an inch in length. Its colour is pale-brown, and its shape rather broad, and flatish. This insect is by means of two long hairs, which, during the summer months creeping about the banks of trees, walls, &c. is considered by Linnaeus as a species of scehdrepandar, but as the legs are double the number of segments on each side, it is more properly referred to Degener, Scorpol, and others, to the present genus. In fact it may be allowed, like the julus complanatus, another slightly flattened species, to form a kind of connective link between the two groups of insects, the scehdrepandars and the aptera. The julus terrestres has 100 legs on each side: the body is a polished black. It inhabits most parts of Europe, under stones and in the earth. See Plate Nat. Hist. fig. 293.

JUNCUS, the rush, a genus of the monogynous order, in the herbaceous class of plants; and in the natural method ranking under the 5th order, tripetaloids. The calyx is hexaplylious; there is no corolla; the capsule is umbilical. There are 39 species, universally known, being very troublesome weeds, and difficult to eradicate. The pith of two kinds, called the conglomeratus and effusus, or round-headed and soft rushes, is used for wicks to lamps and rushlights. The conglomeratus, and acutus or marine rush, are planted with great care on the banks of the sea in Holland, in order to prevent the water from washing away the earth; which would otherwise be removed every tide, if it was not for the roots of these rushes, which are very deep in the mud, and make them raise near the surface in such a manner as to hold the earth closely together. In the summer-time when the rushes are fully grown, they are cut and tied up in bundles, which are dried, and afterwards carried into the larger towns and cities, where they are wrought into baskets, and several other useful things, which are frequently sent into England. These sorts do not grow so strong in this country as in the Netherlands, where they sometimes arrive at the height of four feet and upwards.

JUNGERMANNIA, a genus of the natural order of algae, in the cryptogamia class of plants. The male flower is pollinicated and naked; the female flower is sessile, naked, with roundish seeds. There are 48 species, all natives of Britain, growing in woods, shady places, by the sides of ditches, &c. Many of them are being used for the purpose of giving a pungent and bitterish taste to the water, especially where they are abundant.

JUNCARIA, a genus of the polypogamia segregata order, in the syngnasia class of plants; the common receptacle is chaffy; the perianthum three-flowered; the stigmas tubular, two-apsed; the exterior lip long; the interior one bipartite. There is one species, a native of America.

JUNIPERUS, the juniper tree; a genus of the monadphylia order, in the monoecea class of plants; and in the natural method ranking under the 31st order, conifer. The conglobulosa is a species of juniper, which has no corolla; three stamina; the female calyx tripartite; there are three petals, and as many styles; the berry is trispermous, and equal, by means of three tubercules of the inflated calyx adhering to it. There are three species of juniper, of which one is: The common, or common juniper, grows naturally in many parts of Britain upon dry barren commons, where it seldom rises above the height of a low shrub, which grows naturally in dry shady roads in the Highlands. Of this species there is a variety called Swedish juniper, which grows ten or twelve feet high, very branchy the whole length, with the branches growing more erect, and leaves, flowers, and fruit, like the former.

2. The oxycedrus, or Spanish juniper, rises from ten to fifteen feet high, closely branched from bottom to top; having short, and-shaped, spreading leaves by threes and fours, succeeded by large red-brown berries. 3. The thuniera, or blue-barked Spanish juniper, grows twenty feet high or more. 4. The Virginiana, or Virginia cedar, grows thirty or forty feet high, branching from bottom to top in a conic manner. 5. The Lycia, Lycian cedar, or oblongum tree, grows twenty feet high. 6. The Phoenician, or Phoenician cedar, grows about twenty feet high. It is a native of Portugal. 7. The Bermudiana, or Bermudian cedar, grows twenty or thirty feet high. 8. The sabina, or savin tree; of which there are three varieties, the spreading, upright, and variegated savin. The propagation of all the junipers is by seed, and of the savins by layers and cuttings.

Juniper-berries have a strong, not disagreeable smell; and a warm, pungent, sweet taste, which, if they are long cherished, or previously well bruised, is followed by a bitterness. The pungency seems to be in the bark; the sweet in the juice; the aromatic flavour in oily vesicles spread through the substance of the pulp, and distinguishable even by the eye; and the bitter in the seeds.

JURY. This strong tower of defence of the British constitution, which is one of the leading features of the Magna Charta, is composed of a certain number of persons sworn to enquire of, and try some fact, and declare the truth upon the evidence brought before them.

In criminal cases juries are divided into grand and petty. The grand jury must be all freeholders, but it does not appear that any specific estate has been determined to be necessary; before them the charge is laid, and such twelve or more of them are of opinion that it is well founded, the accusation is dismissed; which they call not incurring a true bill. If they find a true bill, it must afterwards be confirmed by the unanimous assent of a jury of petty officers. There is no suspicion of partiality can possibly rest.

In civil cases juries are divided into common and special. The latter are generally employed in cases where any difficulties with respect to commercial transactions arise, and are best decided by a special jury of merchants.

To obtain a special jury, a motion is made in court, and rule granted, for the sheriff to attend the master, prothonotary, or other proper officer, with his freeholders' book, in the presence of the attorneys on both sides, and to take indifferently forty-eight freeholders, when each party strikes off twelve, and the remaining twenty-four are returned upon the panel.

A common jury is one returned by the sheriff according to the directions of 3 Geo. 11. c. 22, which appoints that the sheriff shall not return a separate panel for every cause, but the same for every cause to be tried at the same assizes, containing not less than forty-eight, nor more than seventy-two; and that their names being written on tickets, shall be put into a box, and when the cause is called, twelve whose names shall not be drawn shall be sworn, unless absent, chal-
A jury when either party is an alien-born, shall be half dozeners, and the other aliens (if there are so many in the place); but when both parties are aliens, it is presumed there is no more partiality for the one than the other, and therefore it was resolved the jury shall all be drawn from aliens.

If a juror receives a bribe from either party, he shall forfeit ten times as much as he has taken, half to the king, and half to him who sues.

A man who threatens or assaults a juror for giving a verdict against him, is punishable by fine and imprisonment; and if he strikes him in court in the presence of the judge, he shall lose his hand and his goods, and the profits of his land during life, and suffer perpetual imprisonment.

IVORY, chur, in natural history, &c., a hard, solid, and firm substance, of a white color, and capable of a very good polish.

If the task of the elephant, and is followed from the base to a certain height, the cavity being filled up with a compact medullary substance, seeming to have a great number of glands in it. It is observed that the Ceylon ivory, being from the island of Ceylon, do not become yellow in the wearing, as all other ivory does; for this reason the teeth of these places bear a larger price than those of the coast of Guinea.

To soften ivory and other bones, lay them for twelve hours in aqua fortis, and then three days in the juice of beets, and they will become so soft that they may be worked into any form. To harden them again, lay them in strong vinegar. Dioscorides says, that by boiling away the juice of six live men with the root of mandragoras, it will become so soft that it may be managed as one pleases.

Ivory-black is the coal of ivory or bone, forged by great heat, while deprived of all access of air.

JUPITER, in astronomy, one of the superior planets, remarkable for its great brightness. See Astronomy.

JUDICIA, whatever is set up in room of a mast, or on the stern of a ship, by the king's command, to decide any cause at all. This privilege is denied to the king, who must assign a reason for the challenge.

If by reason of challenges, or in default of the usual petty cas, no account be laid on the order of the original panel, attires may be awarded both in civil and criminal cases, that is, a sufficient number of persons present in court to be joined to the other jurors, who are however liable to the same challenges as the principal jurors.

The jury, after the proofs are summed up, unless the case is very clear, retire to consider; and are kept without it, drink, fire, or candle, till they are unanimously agreed.

If the jury eat or drink, or have victuals about them, without the consent of the court, before the verdict, it is finable; and if they do it at the charge of him for whom they find, the verdict will be set aside. Also if they speak with either of the parties, or their agents, after they are gone from the bar, or if they receive any fresh evidence, or cast lots to prevent dispute, the verdict is bad.

When the jury have delivered their verdict, and it is recorded in court, they are dismissed.

JUR, chief justices, there are in each of the above courts three puisne justices; there are also several other justices appointed by the king for the execution of the laws; such as the lords justices in eyre of the forests, who are two justices appointed to determine all offenses committed in those justices of assize, of over and terminal, of good delivery, &c. They are also called justices of nisi prius, and so denominated from the words used in a common form of adjournment of a cause to the court of common pleas. See Nisi Prius, Over and Tender, Common Pleas, and King's Bench.

JUSTICES of the Peace. See Peace. JUSTICIARY, or court of Justiciary, in Scotland, a court of supreme jurisdiction in all criminal cases.

This court came in place of the justiciary or justice-general, which was taken away by parliament in 1672, and was erected into a justice or criminal court consisting of a justice-general alterable at the monarch's pleasure, justice clerk, and five other judges, who are lords of session.

This court commonly sits upon Mondays, and has no more business than its commission from the justice clerk. They have four mace, and a doomsman appointed by the lords of the session.

The form of the process is this; the clerk raises a libel or indictment upon a bill passed by any of the lords of that court, at the instance of the pursuer, against the defendant or criminal, who is immediately committed to prison after citation. When the party, without answer, or by his answer, are cited, the day of compearing being come, fifteen of the great assize are chosen to be the assize upon the panel, or prisoner at the bar. The assize sits with the judges to hear the libel read, witnesses examined, and the debates on both sides, which are written verbatim in the adjournal books. The king's advocate pleads for the pursuer, being the king's cause, and other advocates for the prisoner; and the judges then decide, whether they find the libel or indictment either non-relevant, in which case they desert the diet, and absolve or absolve the party accused; or, if relevant, then the assize of jury of fifteen is returned to the clerk, and their order being preparations taken with them, where they choose their chamber and clerk, and consider the libel, deposition, and debates; and bring in their verdict of the panel sealed, guilty or not guilty; if not guilty, the lords absolve; if guilty, they condemn and declare their sentence of condemnation, and command the sentence to be pronounced against the panel by a mace and the mouth of the doomster. The lords of the justiciary likewise go circuits twice a year into the country. See the article Circuit.

JUSTICIES, a writ directed to a sheriff, by virtue of which he is empowered to hold a plea of debt in his county-court for a sum above 40s., though by his ordinary power he has only cognizance of sums under 40s.

JUSTIFICATION, in law, is an affirming or showing good reason in court, why a thing as he is called to answer as to justify it, or prove a relevancy. See HEDERA.

IX. A genus of the monogynia order, in the triandria class of plants; and in the
natural method ranking under the sixth order, Rosaceae. The corolla is hexaepetalous, patent, and equal; there are three stigmata, a little upright and petalous. There are fifty-four species, consisting of heraeanthous, tuberous, and bulbous-rooted flower perennials, from one to two feet high, terminated by hexaepetalous flowers of different colours. They are propagated by offsets, which should be taken off in summer at the decay of the leaves; but as all the plants of this genus are natives of warm climates, few of them can bear the open air of this country in winter.

IXORA, a genus of the tetrandra monogyne class of plants. The corolla consists of a single petal, the tube is cylindrical, very long and slender; the limb is plane, and divided into four oval segments; the fruit is a berry of a roundish figure, with only one cell; the seeds are four in number, convex on one side, and angular on the other. There are nine species, very ornamental shrubs for the stove.

JUSTICIA, Malabar nut; a genus of the monogyne order, in the diandra class of plants; and in the natural method ranking under the 40th order, Passifloraceae. The corolla is zygomorphic, the sepals and petals four, in two distinct series, sometimes five, in one series. There are three stamens, with or without a style; the ovary is superior, and three-celled; the seeds are numerous, minute, and free from the fruit.

John, the twenty fourth letter of our alphabet; as a numeral, denotes 250; and with a line over it, K, 250000.

KEMPERIA, zygodium, a genus of the monogyne order, in the monogyne class of plants, and in the natural method ranking under the eighth order, Scitamineae. The corolla is zygodiate, with three of the segments larger than the rest, patulous, and hermaphroditic. There are two species, 1. The galangus, common galangal, or long zygodium. 2. The rotunda, or round zygodium. Both are perennials in root; but the leaves rise annually in spring, and decay in winter. They flower in summer, the segments of one petal, tubular below, but plain above, and divided into six parts; they continue three or four weeks in beauty, but are never succeeded by seeds in this country. Both these plants must be potted in light moulds, and always kept in a hot-house.

KALI, a genus of marine plants, which are burnt to procure mineral acid.

KALMIA, a genus of the monogyne order, in the deciduous class of plants, and in the natural method ranking under the 15th order, Scitamineae. The calyx is quinquangular; the corolla salver-shaped, formed of five nectaries and a stem on the under or outer sides; the capsule quinquangular. Of this genus there are four species. Those chiefly in cultivation with us are, 1. The fritillaria, a most beautiful shrub, which rises usually to the height of five or six feet, and sometimes twice that height in its native places. The flowers grow in bunches on the tops of the branches to foot-stocks three inches long; they are white, stained with purplish red, consisting of one petal in form of a cup, divided at the verge into three sections: in the middle area a style and 12 stamens, which, when the flower first opens, appear lying close to the sides of the cup at equal distances, their apices being lodged in 10 little hollow cells, which being prominent on the outside, appear as many little tubercles. This plant is a native of Carolina, Virginia, and other parts of the northern continent of America, yet is not common, but found only in particular places; it grows on rocks hanging over rivulets and running streams, and on the sides of barren hills.

2. The angustifolia, rises to the height of about 16 feet, with evergreen leaves. The flowers grow in clusters, and when bowed, appear white; but on a near view, are of a faint bluish colour, which as the flower deca
ges grows stronger.

KAOLIN, the name of an earth which is used as one of the two ingredients in oriental porcelain. See Porcelain.

KEEL, or KEELING, in the sea-language, is the winding of old ropes about cables, to prevent them from galling.

KEDGING, in the sea-language, is when a ship is brought up or down a narrow river by means of the tide, the wind being contrary.

KEEL, the lowest piece of timber in a ship, running her whole length, from the lower part of her stem to the lower part of her stern-post. Into it are all the lower fast
tocks fastened; and under part of it, a false keel is often used.

Of this genus there are three species. Those chiefly in cultivation with us are, 1. The fritillaria, a most beautiful shrub, which rises usually to the height of five or six feet, and sometimes twice that height in its native places. The flowers grow in bunches on the tops of the branches to foot-stocks three inches long; they are white, stained with purplish red, consisting of one petal in form of a cup, divided at the verge into three sections: in the middle area a style and 12 stamens, which, when the flower first opens, appear lying close to the sides of the cup at equal distances, their apices being lodged in 10 little hollow cells, which being present on the outside, appear as many little tubercles. This plant is a native of Carolina, Virginia, and other parts of the northern continent of America, yet is not common, but found only in particular places; it grows on rocks hanging over rivulets and running streams, and on the sides of barren hills.

2. The angustifolia, rises to the height of about 16 feet, with evergreen leaves. The flowers grow in clusters, and when bowed, appear white; but on a near view, are of a faint bluish colour, which as the flower deca
ges grows stronger.

KAOLIN, the name of an earth which is used as one of the two ingredients in oriental porcelain. See Porcelain.

KEELE, or KEELING, in the sea-language, is the winding of old ropes about cables, to prevent them from galling.

KEDGING, in the sea-language, is when a ship is brought up or down a narrow river by means of the tide, the wind being contrary.

KEEL, the lowest piece of timber in a ship, running her whole length, from the lower part of her stem to the lower part of her stern-post. Into it are all the lower fast
tocks fastened; and under part of it, a false keel is often used.

Each of these species is divided into two sub-species.

Keeschlieffen, common: colour blackish grey or greenish: often traversed by veins of quartz: surface smooth: texture compact: fracture splintery, or imperfectly conchoidal: composed according to Wiegleb of 75.00 silica
10.00 lime
4.25 magnesia
5.34 iron
5.07 inflammable matter

98.14

Keelian stone is another species of kesschleffien, but more interspersed by veins of quartz: fracture even: sometimes inclining to conchoidal: specific gravity 2.590: powder black: co.our greyish black.

This, or a stone similar to it, was used by the ancients as a touch-tone. They drew the metal to be examined along the stone, and judged of its purity by the colour of the metallic streak. On this account they called it eisame, "the knave." They called it also

Kalian stone, because, as Linaeraphus ju-
forms us, it was found most abundantly in the river Timoüs in Lydia.

KIEF, in the glass trade, a term used for a sort of potash made use of in many of the glass works, particularly for the green glass. It is the calcined ashes of a plant called by the same name; and in some places of sea-land, or laces, a sort of thick-leaved fucus or seaweed. This plant is thrown on the rocks and shores in great abundance, and in and after the summer months is raked together and dried as hay in the sun and wind, and afterwards burnt to the ashes called kief.

KING, a shell found on the coast of Sumatra; it is sometimes three or four feet in diameter, as white as ivory. See Madden's Hist. of Sumatra.

KENAS, in the sea-language, doubilings in a rope or cable, when handed in and out, so that it does not run easy; or, when any rope makes turns or twists, and does not run free in the block.

SACRALLINE, K. KEMI. See Cocceus.
KERNER MINERAL, a compound of sulphur of antimony and potash.
KEITH, in naval architecture, a vessel with two masts, usually applied to one carrying sails, or one-hour mowers.
KEVLAR, in ship building, a piece of plank faced against the quickwork on the quarter-deck, in the shape of a semicircle; about which the running rigging is belayed.
KEY, in music, a fundamental note or tone to which the whole scale of a movement has a certain relation or bearing, to which the modulations are referred and accommodated, and in which it both begins and ends. There are but two species of keys, one of the major, and one of the minor mode; all the keys in which we employ sharps or flats being deduced from the natural keys of C major, and A minor, of which indeed they are only transpositions.
KEYSTONE. See Architecture.
KEYS. See ORGAN, HARPSICHORD, &c.

KIDNAPPING, is the forcible taking and carrying away a man, woman, or child, from their own country, and sending them to another. This is an offence at common law, and punishable by fine, imprisonment, and pillory.

By stat. 11 and 12 W. III. c. 7, if any captain of a merchant vessel shall during his being abroad force any person on shore, and wilfully leave them behind, or refuse to bring home all such men as he carried out, if able and desirous to return, he shall suffer three months imprisonment. Exclusive of the above punishment for this as a criminal offence, the party may recover upon an action for common law damages for the civil injury.

KIDNEY: See ANATOMY.

RIFFEKIL. This mineral is dug up near Tonkel in Natalia, and is employed in forming the bowls of Turkish tobacco-pipes. Its use in supports a monitory of dervises established near the place where it is dug. It is found in a large fissure, six feet wide, in grey calcareous earth. The workmen assert that it grows again in the fissure, and puffs itself up like froth. This mineral, when fresh dug, is of the consistence of wax; it feels soft and greasy; its colour is white; it specific gravity 1.050; when thrown on the fire it swells, emits a fetid vapour, becomes hard, and perfectly white.

According to the analysis of Klaproth, it is composed of 30.50 silica 17.25 magnesium 9.60 potash 5.00 carbonic acid .50 lime.

KIGGELARIA, a genus of the decapoda order, in the diecia class of plants, and in the natural method ranking under the 5th order, columnifer. The male calyx is quinquepartite; the corolla pentapetalous; there are five trilobate gladioluses, the anthers are perforated at top; the female calyx and corolla as in the male; there are five styles; the capsule unilocular, quinquinalved, and papyraceous. There is but one species, viz. the Africana. As this is a native of warm climates, it must be constantly kept in a stove in this country. It is propagated by seeds, layers, or cuttings, though most readily by seeds.

KILDERKIN, a liquid measure containing four imperial gallons.
KINDRED. See DESCENT.

KING, signifies him who has the highest power and absolute rule over the whole land; and therefore the king is, in intention of law, charles those defects which common persons are subject to; for he is always sup- posed to be of full age, though ever so young. He proclaims wars and embus to offenders against the crown and dignity, except such as he binds by acts not to forgive. The law ascribes to his majesty, in his political capacity, an absolute immortality. The king never dies. For immediately on the decease of the reigning prince in his natural capacity, his imperial dignity, by act of law, without any interregnum or interval, is vested at once in his heir, who is co instanti king to all intents and purposes. And so tender is the law of supposing even a possibility of his death, that his natural dissolution is generally called his death; and it is merely a transfer of property.

By the articles of the union of the two kingdoms of England and Scotland, all persons and persons marrying papists, are forever excluded from the imperial crown of Great Britain; and in such case, the crown shall descend to such person being a protestant, as shall have inherited the same, in case such papist, or person marrying a popist, was naturally dead. 5 Anne, c. 5.

KING'S BENCH. The king's bench is the supreme court of common law in the kingdom, and is so called because the king used to sit there in person; it consists of a chief justice, and four other justices, who are by office the sovereign conservators of the peace, and supreme coroners of the land. This court has a peculiar jurisdiction, not only over all capital offences, but also over all other misdemeanours of a public nature, tending either to a breach of the peace, or to oppression, or faction, or any manner of misgovernment. It has a discretionary power of inflicting exemplary punishment on offenders, either by fine, imprisonment, or such other infamous punishment as the nature of the crime, considered in all its circumstances, shall require.

The jurisdiction of this court is so trans- scendent, that it keeps all inland jurisdictions within the bounds of their authority; and it may either remove their proceedings to be determined here, or prohibit their progress below; it superintends all civil corporations in the kingdom; commands magistrates and others to do what their duty requires, in every case where there is no pecuniary recovery; protects the liberty of the subject, by speedy and summary interposition; takes cognizance both of criminal and civil causes; the former what is called the crown side, or crown of- fice; the latter in the pleas side of the court.

This court has cognizance on the plea side of all actions of trespass, or other injury alleged to be committed vi et armis; of actions for forgery of deeds, maintenance, conspiracy, deceit, and actions on the case which allege any falsity or fraud.

In proceedings in this court, the defendant is arrested for a supposed trespass, which in reality he has never committed; and being thus in the custody of the marshal of this court, the plaintiff is at liberty to proceed against him for any other personal injury, which surmise of being in the custody of the marshal, the defendant is not at liberty to dis- mise.

This court is likewise a court of appeal, into which may be removed, by writ of er- ror, all determinations of the court of common pleas, and of all inferior courts of record in England.

KING'S BENCH PRISON. King's bench new rules. East 30 G. III. it is ordered by the court, that from and after the first day of Trinity term next, the rule made in the sixth day of the reign of king George I. and all other rules for establishments of the king's bench prison, shall be, and the same are hereby, repealed. And it is further or- dered, that from and after the said first day of Trinity term next, the rules of the king's bench prison shall be comprised within the bounds following, exclusive of the public houses hereinafter mentioned; that is to say, from Great Cumbe-court to the parish of St. George the Martyr, in the county of Sur- rant, the north side of Queen's-walk, and Meanchey-walk, to Blackfriars' road, along the western side of the said road to the obe- lok, and thence along the south-west side of the London-road, round the direction post in the north, along the public houses known by the sign of the Elephant and Castle, and thence along the eastern side of Newing- ton caseway to Great Cumbe-court afo- said: and it is also ordered, that the new goal Souther-rk, and the highway, exclusive of the house on each side of it, leading from the king's bench prison to the said new goal, shall be: within and part of the said rules. And it is hereby ordered, that all taverns, victualling houses, ale-houses, and wine-merchants' and houses or places licensed to sell gin, or other spirituous liquors, shall be excluded out of, and deemed no part of the said rules. It is ordered, that from and after the first day of Trinity term next, no prisoner in the king's bench prison, or within the rules afo- said, shall have, or be entitled to have, day rules above three days in each term. And it is further ordered, that every such prisoner shall return within the walls or rules of the house, the house before the o'clock on the evening day on which such rule shall be granted.

KING'S PALACE. The history of the king's
LAB

palace at Westminster extend from Charing-cross to Westminster-hall, and shall have such privileges as the ancient palaces. 38 II. V. H. c. 19. 1219.

KING'S FISHER. See ALCEDO.

KLEINSTEIN: this mineral comprises whole mountains. They are usually insinuated; and like basalt, shew a tendency to assume the form of four-sided prisms. Its colour is usually deep grey, of various shades; but most commonly greenish shades; but shades pulled together, which gives it the appearance of being spotted. Found not only constituting mountains, but also in globular masses, &c. Internal tissue arrest chiefly from so the crystals of rounded and felspar which it contains. Structure sably. Texture compact. Fracture usually splintery; sometimes conchoidal. Brittle. Gives a clear sound when struck with a hammer. Specific gravity 2.573. Pouder light grey. Melts easily into a glass. A species analysed by Klaproth yielded 37.22 silica. 23.50 alumina 2.75 lime 3.35 oxide of iron 0.65 carbonate of manganese 8.10 soda 3.00 water.

98.10

KLEINHOVY, a genus of the class of and order granae decalcified: the calyx is five-leaf; corolla five-petalled; nect. bell-shaped; ap. dilated, five-lobed. There is one species, a tree of Java.

KNAPSACK, a rough leather or canvas bag, which is strapped to an infantry soldier's back when he marches, and which contains his necessaries. Square knapsacks are supposed to be most convenient. They should be made with a division to hold the shoes, blacking-balls, and brushes, separate from the rest. White goat-skins are sometimes used, but we do not conceive them to be equal to the painted canvas ones. Soldiers are put under stoppages for the payment of their knapsacks, which after six years become their property.

KNAPUTIA, a genus of the monogynia order, in the tetrandrae class of plants, and in the natural method ranking under the 48th order, aggregate. The common calyx is oblong, simple, quinquiflorous; the proper one simple, superior; the corollas irregular; the receptacle naked. There are four species, chiefly annuals of the Levant.

KNEE. See Anatomy.

KNEE, in a ship, a crooked piece of timber, bent like a knee, used to bind the beams and futtocks together, by being bolted fast into them both. These are used about all the decks.

KNEES, curving, in a ship, those timbers which extend from the sides to the hatchway, and bear up the deck on both sides.

KNIGHT, properly signifies a person, who, for his virtue and martial prowess, is by the king raised above the rank of gentleman into a higher class of dignity and honour. The ceremonies at the creation of knights have been various; the principal was a kiss on the ear, and a stroke with a sword on the shoulder; they put on him a shoulder-belt, and a gilt sword, spurs, and other military accoutrements; after which, being armed as a knight, he was led to the church in great pomp. Camden describes the manner of making a knight-bachelor among us, which is the least, though the most ancient order of knighthood: to be thus: the person kneeling was gently struck on the shoulder by the prince, and accosted in these words, 'rise,' or 'be a knight in the name of God.' For the several kinds of knights among us, see BARONET, BARONET, BATH, GARTER, &c.

KNIGHTS of the shire, or KNIGHTS of parliament, in the British polity, are two knights or gentlemen of estate, who are elected, on the king's writ, by the freeholders of every county, to represent them in parliament. The qualification of a knight of the shire is to be possessed of 600l. per ann., in a freehold estate. Their expenses during their sittings were by a statute of Henry VIII. to be defrayed by the county; but this is now never required.

K. or L, the eleventh letter of our alphabet, as a numeral, denotes 10; and with over it, thus, L, 5000.

LA, in music, the syllable by which Guidi denoted the last sound of each hexachord: if it begins in C, it answers to our A; if in G to E; and if in F to D.

LABARUM, in Roman antiquity, the standard borne before the Roman emperors; being a rich purple streamer, supported by a spear.

LABDANUM, or Ladanum. This resin is obtained from the eucalyptus, a shrub which grows in Syria and the Grecian islands. The surface of the shrub is covered with a viscid juice, which when concreted forms ladanum. It is collected while moist by drawing over it a kind of rake with thongs fixed to it; from these it is afterwards scraped with a knife. The best is in masses almost black, and very soft, having a fragrant colour and a bitterish taste. When dissolved in alcohol, it leaves behind it a fetid smell. The specific gravity of this resin is about 1.18. See RESINS.

LABEL, in heraldry, a pile usually placed in the middle along the chief of the coat, without touching its extremities.

LABLE, or LAMB, a cereal. A chemical laboratory, though extremely useful, and even essential to all who embark extensively in the practice of chemistry, either as an art, or as a branch of liberal knowledge, is by no means required for the performance of those simple experiments which furnish the evidence of the fundamental truths of the science. A room that is well lighted, easily ventilated; and destitute of any valuable furniture, is all that is absolutely necessary for the purpose. It is even advisable that the construction of a regular laboratory should be deferred till the student has made some progress in the science; for he will then be better qualified to accommodate his plan to his own peculiar views and convenience.
LABORATORY.

It is scarcely possible to offer the plan of a laboratory, which will be suitable to every person, and to all situations; or to suggest anything more than a few rules that should be observed in it. Different apartments are required for the various classes of chemical operations. The principal one may be on the ground floor; twenty-five feet long, fourteen or sixteen feet wide, and open to the roof, in which there should be contrivances for allowing the occasional escape of suffocating vapours. This will be destined chiefly for containing furnaces, both fixed and portable. It should be amply furnished with shelves and drawers, and with a large table in the centre, the best form of which is that of a double cross. Another apartment may be appropriated to the minister operations of chemistry; such as those of precipitation on a small scale, the processes that require merely the heat of a lamp, and experiments on the gases. In a third, of smaller size, may be deposited accurate balances, and other instruments of considerable nicety, which would be injured by the acid fumes that are constantly spread through a laboratory.

The following are the principal instruments that are required in chemical investigations; but it is impossible, without entering very closely into details, to enumerate all that should be in the possession of a practical chemist.

1. Furnaces. These may either be formed of solid brickwork, or of such materials as are on their removal from place to place. See Furnace, and Chemistry.

2. For containing the materials, which are to be submitted to the action of heat in a wind furnace, vessels called crucibles are employed. They are most commonly made of a mixture of fire-clay and sand, occasionally with the addition of plumbago, or black lead. The Hessian crucibles are best adapted for supporting an intense heat without melting; but they are liable to crack when suddenly heated or cooled. The porcelain crucibles made by Messrs. Wedgwood, are of much purer materials, but are still more apt to crack on sudden changes of temperature; and when used, they should therefore be placed in a crucible of fire-clay, the interval being filled with sand. The black-lead crucibles resist very sudden changes of temperature, and may be repeatedly used; but they are destroyed when some saline substances (such as nitre) are melted in them, and are consumed by a current of air. For certain purposes crucibles are formed of pure silver or platinum. Their form varies considerably; but it is necessary, in all cases, to make the edge of the bases of the crucibles of the bars of the grate, by a stand. For the purpose of submitting substances to the continued action of a red heat, and with a considerable surface exposed to the air, a hollow-arched vessel, with a bottom flat, termed a muffle, is commonly used.

3. Evaporating vessels should always be of a flat shape, so as to expose them extensively to the heat. They are formed of glass, of earthenware, and of various metals. Those of glass are with difficulty made sufficiently thin, and are often broken by changes of temperature; but they have a great advantage in the smoothness of their surface, and in resisting the action of most acid and corrosive substances. Evaporating vessels of porcelain, or Wedgwood's ware, are next in utility, are less costly, and less liable to be cracked. They are made both of glazed and unglazed ware. For ordinary purposes, the latter are preferred; but the unglazed should be employed when great accuracy is required, since the glazing is acted on by several chemical substances. Evaporating vessels of glass, or porcelain, are generally lined up to their edge in sand; but those of various metals are placed immediately over the naked flame. When the glass or porcelain vessel is very thin, and of small size, it may be safely placed on the ring of a brass stand, and the flame of an Argand's lamp, cautiously regulated, may be applied beneath it. A lamp thus supported, so as to be raised or lowered at pleasure, on an upright pillar, to which rings of various diameters are attached, will be found extremely useful; and when a strong heat is required, it is advisable to employ a lamp provided with double concentric wicks.

4. In the process of evaporation, the vapour for the most part is allowed to escape; but in certain chemical processes, the collection of the volatile portion is the principal object. This process is termed distillation. See Distillation.

The contents of a lute, however, can only be employed for volatilizing substances that do not act on copper, or other metals, and is, therefore, limited to very few operations, and on that account plumbago and retorts are necessary.

In several instances, the substance raised by distillation, is partly a condensable liquid, and partly a gas, which is not condensed till it is brought into contact with water. To effect this double purpose, a series of receivers termed Woolley's apparatus is employed.

See Chemistry.

When a volatile substance is submitted to distillation, it is necessary to prevent the escape of the vapour through the junctures of the vessels; and this is accomplished by the application of lutes. The most simple method of confining the vapour is obviously useless; it would be to connect the places of juncture accurately together by grinding; and according the neck of the retort is sometimes ground to the mouth of the receiver. This, however, adds too much to the expense of the apparatus to be generally practised.

When the distilled liquid has no corrosive property, (such as water, alcohol, ether, &c.) slips of moistened bladder, or paper or linen spread with flour paste, white of egg, or mucilage of gum Arabic, sufficiently answer the purpose. The substance remains, after expressing the oil from bitter almonds, and which is sold under the name of almond meal or flour, forms a useful lute, when mixed to the consistency of glaziers' putty, or with water or mucilage.

For confining the vapour of acid or highly corrosive substances, the fat lute is well adapted. It is formed by beating perfectly dry and finely-sifted tobacco-pipe clay with painters' drying-oil, to such a consistency that it may be moulded by the hand. The same clay, beaten up with as much sand as it will bear without losing its tenacity, with the addition of cut tow, or of horse-dung, and a proper quantity of water, furnishes a good lute, which has the advantage of resisting a considerable heat, and is applicable in those cases where the fat lute would be melted or destroyed. Various other lutes are recommended by chemical writers; but few that have been enumerated are found to be amply sufficient for every purpose. See Lute.

On some occasions, it is necessary to practice the return of too sudden changes of temperature by a process called cooling. For glass retorts, a mixture of common clay or lamp with sand, and cut shreds of flax, may be employed. If the distillation is performed by a sand heat, the coating needs not to be applied higher than that part of the retort which is heated in sand; but if the process is performed in a wind furnace, the whole body of the retort, and that part of the neck also which is exposed to heat, must be carefully coated. To this kind of distillation, however, earthen retorts are not adapted; and they may be covered with a composition originally recommended by Mr. Willis. Two ounces of borax are to be dissolvd in a pint of boiling water, and a sufficient quantity of slaked lime is added, until the thickness of cream is thus to be applied by a painter's brush, and allowed to dry. Over this a thin paste is afterwards to be applied, formed of slaked lime and common fiescoedile, well mixed and strained through a plastic mill. In a day or two, the coating will be sufficiently dry to allow the use of the retort.

For joining together the parts of iron vessels used in distillation, a mixture of the finest China clay, with solution of borax, is well adapted. In all cases, the different parts of any apparatus made of iron should be accurately fitted by boring and grinding, and the above lute is to be applied to the part which is to receive an aperture. This will generally be sufficient without any exterior luting; otherwise the lute of clay, sand, and flax, already described, may be used.

In every instance, where a lute or coating is applied, it is advisable to allow it to dry before the distillation is begun; and even the fat lute, by exposure to the air during one or two days after its application, is much improved. With lute and sand heat, however, it is perfectly useless, except it is previously quite dry. In applying a lute, the part immediately over the juncture should swell outwards, and its diameter should gradually diminish on each side.

Besides the apparatus already described, a variety of vessels and instruments are necessary, having little resemblance to each other in the purposes to which they are adapted. Glass vessels are very essential for effecting solution, which often requires the application of heat, and sometimes for a considerable duration. In the latter case it is termed digestion, and the vessel called a digestion is the most frequent performing it. When solution is quickly effected, a bottle, with a rounded bottom, may be used, or a common Florence-coil flask serves the same purpose extremely well, and is much preferable, when subjected to changes of temperature.

Glass rods, of any size, strength, and span of the same material, or of par-
retain, are useful for stirring acid and corrosive liquids; and a stock of cylindrical tubes of various sizes, is required for occasional purposes. It is necessary also to be provided with a series of glass measures, graduated to half-cups, ounces, and pints.

Accurate beams, scales, and various redial instruments, with corresponding weights, some of which are capable of weighing several pounds, while the smaller size ascertain a minute fraction of a grain, are essential instruments in the chemical laboratory. So also are mortars of different materials, such as of glass, porcelain, agate, and metal. Wooden stands of various kinds for supporting receivers, should be provided. For purposes of this sort, and for occasionally raising to a proper height any article of apparatus, a series of blocks, made of well-seasoned wood, eight inches (or any other number) square, and respectively four, two, one, and half an inch in thickness, will be found extremely useful; since by combining them in different ways, no less than thirty-one different heights may be attained.

The blowpipe is an instrument of much utility in chemical researches. A small one, invented by Mr. Bunsen, with a flat cylindrical bunsen for condensing the vapour of the breath, and for containing caps, to be occasionally applied with apertures of various sizes, is perhaps the most commodious form. A blowpipe, which is supplied with air from a pair of double bellows, worked by the foot, may be applied to purposes that require both hands to be left at liberty, and will be found useful in blowing glass, and in blowing vessels. The latter purpose, however, may be accomplished by holding them over an Argand's lamp with double wicks.

Laboratory signifies also in military affairs, that place where all sorts of fire-works are prepared both for actual service, and for pleasure, viz. quick matches, fusees, portières, grape-shot, case-shot, carcasses, hand-grenades, cartridges, shells filled and fuses fixed, &c.

Lamb, a genus of fishes of the order thalacerea; the typical character is, teeth strong and subacute: the grinders sometimes, as in the sparrow, convex and crowded: lips thick and doubled: rays of the dorsal fin, in some species, elongated into soft processes. Gill-covers unpaired and scaly.

Laurus nobilis, var. robustus. Labrus, a sort of fish resembling a mackerel, which is a food fish, found in the Mediterranean, sometimes wandering into rivers. There are 41 species belonging to this genus, all of which are but imperfectly understood.

Lavern. See Master and Servant.

Labyrinth, in gardening, a winding maze walk between hedges, through a wood or wilderness. The chief aim is to make the walks so perplexed and intricate, that a person may lose them in them, and to cover them, with as great a number of disappointments as possible. They are rarely to be met with, except in great gardens; as Versailles, Hampton-court, &c.

Lac, an appellation given to several chemical preparations.

Lac. This resin exudes from the tree Vol. II.
This numerous genus may be divided into the following sections, viz.:

1. Crocodiles, furnished with very strong scales.

2. Gunnas, and other lizards, especially with serrated or spiny tails.

3. Cordyles, with dentateurated, and sometimes spiny scales, either on the body or tail, or both.

4. Lizards proper, smooth, and the greater number furnished with broad square scales or plates on the abdomen.

5. Chamaeleons, with granulated skin, large head, long missile tongue, and cylindrical tail.

6. Gekkos, with granulated or tuberculated skin, and lobated feet, with the toes lamellated beneath.

7. Scinks, with smooth, fishy, scales.

8. Salamanders, newts, or eels, with soft skins, and of which some are water-lizards.

9. Snake-lizards, with extremly long bodies, very short legs, and minute feet.

The above divisions neither are, nor can be, perfectly precise; since species may occur which may, with almost equal propriety, be referred to either of the neighboring sections; but, in general, they will be found useful in the investigation of the species.

The following are the most noted:

1. Lacerta crocodilus, or crocodile. The crocodile, so remarkable for its size and powers of destruction, has in all ages been regarded as one of the most formidable animals of the warmer regions. It is a native of Asia and Africa, but seems to be most common in the latter; inhabiting large rivers, as the Nile (see Plate Nat. Hist. t. 237), the Niger, Sce, and preying principally on fish, but occasionally seizing on almost every animal which happens to be exposed to its rapacity. The size to which the crocodile sometimes arrives is prodigious; specimens being frequently seen of 20 feet in length, and instances are commemorated of some which had exceeded the length of 30 feet. The armour with which the upper part of the body is invested is the most elaborate of nature's mechanisms. In the full-grown animal it is so strong and thick as easily to repel a musket-ball; on the longer parts it is much thinner, and of a more pliable nature, and appears as if covered with the most regular and curious carved work: the colour of a full-grown crocodile is blackish-brown above, and yellowish-white beneath; the upper parts of the legs and the sides varied with deep yellow, and in some parts tinged with green. In the young animals the colour on the upper parts is a mixture of brown and pale yellow, the under parts being nearly white: the eyes are protected by a firm membrane, or transparent movable pellicle, as in birds; the mouth is of vast width, the rictus or gape having a somewhat fleshy outline, and both jaws being furnished with very numerous sharp-pointed teeth, of which those about the middle part of each jaw considerably exceed the rest in size, and seem analogous to the canine teeth in the vipers: quadrupeds or mammalia: the number of teeth in each jaw is 40, or 50, and it is very proper to alternate with each other when the mouth is closed; on taking out the teeth and examining the alveoli, it has been found that small teeth were forming beneath, in order to supply the loss of the others when shed.

The auditory foramina are situated on the top of the head, above the eyes, and are moderately large, oval, covered by a membrane, having a longitudinal slit or opening, and thus in some degree resembling a pair of small ears. The legs are short, but strong and muscular, the fore legs are short, curved, and the other legs are long, very long, of a laterally compressed form, and furnished above with an upright process, formed by the gradual approximation of two elevated crests proceeding from the lower part of the back.

The crocodile in a young state is by no means to be dreaded, its small size and weakness preventing it from being able to injure any of the larger animals; it therefore content itself with fish and other small prey; and such as have occasionally been brought to Europe are so far from being formidable or ferocious, that they may be generally trusted with, and domesticated among, birds, insects, or fish, and even among other quadrupeds, or the effect of a cold climate, seem much inclined to torpidity; but in the glowing regions of Africa, where it arrives at its full strength and power, it is justly regarded as the most formidable of all the inhabitants of the rivers. It lies in wait near the banks, and snatches dogs and other animals, swallowing them instantly, and then plunging into the river, and seeking some retired part, where it may be concealed: it then invites it to its prey. In its manner of attack it is exactly imitated by the common lacertas pustularis, or water-newt, which, though not more than four or five inches long, will with the greatest case swallow an insect of more than an inch in length: and that at one single effort, and with a motion so quick, that the eye can scarcely follow it. It poises itself in the water, and having gained a convenient opportunity, it advances in the most rapid and irresistible manner to the insect, and swallows it. If, therefore, a small lizard of four or five inches only in length can thus instantaneously swallow an animal of a fourth part of its own length, we may judge of the force of a crocodile of 18, 20, 22, or 25 feet long, should suddenly ingress a dog or other quadruped.

Crocodiles, like the rest of the lacertas, are oviparous: they deposit their eggs in the sand or mud near or on the banks of the rivers they frequent, and the young when hatched immediately proceed to the water: but the major part are said to be commonly devoured by other animals, as ichneumons, and other carnivorous animals, which are said to form one of their favourite repasts.

In the large rivers of Africa crocodiles are said to be sometimes seen swimming together in vast shoals, and resembling the trunk of so many large trees dancing on the water.
LACERTA.

The negroes will sometimes attack and kill a single crocodile, by stabbing it under the belly, where the skin, at the interstices of the scales, is soft and flexible. It is also, in some countries, the custom to hunt the crocodile by means of strong dogs, properly trained to the purpose, and armed with spiked collars. It is likewise pretended, that in some parts of Africa crocodiles are occasionally tamed; and it is said that they form an article of royal magnificence with the monarchs of those regions, being kept in large ponds or lakes appropriated to their residence. We may add, that the ancient Romans exhibited these animals in their public spectacles and triumphs, Scarsus, during his availsip, treated the people with a sight of five crocodiles, escaped in a temporary lake; and Augustus introduced one into his triumph over Cleopatra, as well as several others, for the entertainment of the people.

2. Lacerta alligator. So very great is the general resemblance of this animal and the crocodile, that many naturalists have been strongly inclined to consider it as a mere variety, rather than a distinct species. The more accurate discrimination, however, of Blumenbach and some others seems to prove that the alligator or American crocodile is specifically distinct from the nilotic, though the difference is not so immediately to strike a general observer. The leading and peculiar characters, which constitute a distinction of species, seems to be, that the head of the alligator is rather smooth on the upper part than marked with those very rugged and hard carinated scales which appear on that of the crocodile; and that the snout is considerably flatter and wider, as well as more rounded at the extremity. The alligator arrives at a size not much inferior to that of the crocodile, specimens having been often seen of 18 or 20 feet in length.

"Though the largest and greatest numbers of alligators," says Catesby, "inhabit the torrid zone, the country abounds in them 10 degrees more north, particularly as far as the river Neus in North Carolina, in the latitude of about 33 degrees, beyond which I have never heard of any, which latitude nearly answers to the southern limits of Africa, where they are likewise found. They frequent not only salt rivers near the sea, but streams of fresh water in the upper parts of the country, and in lakes of salt and fresh water, on the banks of which they lie lurking among reeds, to surprise cattle and other animals. In Jamaica, and many parts of the continent, they are found about 20 feet in length: they cannot be more terrible in their aspect than they are formidable and mischievous in their nature, sparing neither man nor beast they can surprise, pulling them down under water, that being dead, they may with greater facility, and without struggle or resistance, devour them. As quadrupeds do not so often come in their way, they almost subsist on fish; but as Providence, for the preservation, or to prevent the extinction of these harmless creatures, has in many instances re-striped the devouring appetites of voracious animals, by some impediment or other, so this de-troucing monster, by the close connection of his vertex, can neither swim nor run any other way than straight forward, and is consequently disabled from turning with that agility requisite to catch his prey by pursuit therefore they do it by surprise in the water as well as by land; for effecting which nature seems in some measure to have recompensed their want of agility, by giving them a power of deceiving and catching their prey, such or such a manner, as well as by the outerform and colour of their body, which on land resembles an old dirty log or tree, and in the water frequently lies floating on the surface, and there has the like appearance; and has a silent artifice, fish, fowl, turtle, and all other animals, are deceived, suddenly caught, and devoured.

In Carolina they lie torpid from about October to March, in caverns and hollows in the banks of rivers, and at their coming out in the spring make an hideous bellowing noise. The hind part of their belly and tail are eaten by the Indians. The flesh is delicately white, but has so perfumed a taste and smell that I never could relish it with pleasure.

3. Lacerta gaugettus. The gaugettic crocodile is so strikingly distinguished both from the nilotic and the alligator by the peculiar form of the mouth, that it is hardly possible, even on a cursory view, to confound it with the latter. It is of an incredibly long, narrow, and perfectly straight, and the upper mandible terminated above an elevated tubercle. In a very young state the length and narrowness of the snout are still more conspicuous than in the full-grown animal. The teeth are nearly double the number of those of the common crocodile, and are of equal size throughout the whole length of the jaws. This species is a native of India, and is principally seen in the Ganges, where it arrives at a size at least equal to the nilotic crocodile.

4. Lacerta iguana. Though the lizard tribe affords numerous examples of strange and peculiar form, yet few species are perhaps more eminent in this respect than the guana, which grows to a very considerable size, and is often seen of the length of three, four, and even five feet. It is a native of many parts of America and the West Indian islands, and is occasionally to be found in the East Indies. Its general colour is green, but with much variation in the tinge of different individuals: it is generally shaded with brown in some parts of the body, and sometimes this is even the predominant colour. The back of the guana is very strongly serrated; and this, together with the gular pouch, which it has the power of extending or inflating occasionally to a great degree, gives a formidable appearance to an animal otherwise harmless. It inhabits rocky and woody places, and feeds on insects and vegetables. It is itself reared an excellent food, being extremely nourishing and delicate; but it is observed to deserve the common method of catching it by casting a noose over its head, and thus drawing it from its situation; for seldom makes an effort to escape, but stands looking intently at its disposer, in case it is found to be the same time in an extraordinary manner.

The guana may be easily tamed while young, and is both an innocent and beautiful creature in that state.

5. Lacerta basiliscus. The basilisk of the ancients, supposed to be the most malignant of all poisonous animals, and of which the very aspect was said to be fatal, is a fabulous existence, to be found only in the representations of painters and poets.

But the animal known in modern natural history by this name is a species of lizard, of a very singular shape and habit, particularly distinguished by a long and broad wing-like process or expansion continued along the whole length of the back, and to a very considerable distance on the upper part of the tail. There is generally a rare internal radiating array to those in the fins of fishes, and still more so to those in the wings of the draco volans, or flying lizard. This process is of different elevation in different parts, so as to appear strongly simulated and outlined, and is capable of being either dilated or contracted at the pleasure of the animal. The occiput or hind part of the head is elevated into a very conspicuous pointed hood or hollow crest.

It is astonishing its formidable appearance the basilisk is a perfectly harmless animal, and, like many other of the lizard tribe, resides principally among trees, where it feeds on insects, &c. The colour of the basilisk is a pale olive green in some parts of the back, with some darker or lighter lines drawn towards the whole body, which is principally found in South America, and is sometimes considerably exceeds the length before mentioned, measuring three feet, or even more, from the nose to the extremity of the tail. It is said to be an animal of great agility, and is capable of swimming occasionally with perfect ease, as well as of springing from tree to tree by the help of its own power, which it expands in order to support its flight.

6. Lacerta calotes. This species is considerably allied to the common guana in habit or general appearance; but is of much smaller size, rarely exceeding the length of a foot and a half from the tip of the nose to the extremity of the tail. It is also destitute of the very large gular pouch, so conspicuous in that animal; instead of which it has merely a slight inflation or enlargement on that part. In colour it is more varied than that of this tribe; but it is commonly of an elegant bright blue, variegated by several broad, and somewhat irregular white or whish transverse bands on each side of the body and tail. It is a native of the warmer regions of both Asia and Africa, and is found in many of the Indian islands, and particularly in Ceylon, in which it is common. According to the count de Capepe it is also found in Spain, &c. and is said by that author to wander about the tops of bushes in quest of spiders; and he observes, that it is even reported to prey on rats, and to fight with small serpents in the manner of the common green lizard and some others. See Plate Nat. Hist. Fig. 230.

7. Lacerta montana, the monitor, or montitory lizard, is one of the most beautiful of the whole tribe, and is also one of the largest; sometimes measuring not less than four or five feet from the tail up. The form of its body is slender and elegant, the head being small, the snout gradually tapering, the limbs moderately slender, the tail laterally compressed, and inenable decreasing towards the tip, which is very slender and sharp. Though the colour of this lizard are
simple, yet such is their disposition, that it is impossible to survey their general effect without admiration. In this respect, however, the animal varies perhaps more than most others of its tribe. It is commonly black, with the abdomen white, the latter located on the underside of the body. The skin, when distended, is either in the form of several pointed bands, besides which the whole body is generally ornamented by several transverse bands consisting of white annular spots, while the head is marked with various streaks of the same colour, the limbs with very numerous round spots, and the tail with broad, distant, transverse bands. It is a native of South America, where it frequently occurs in woody and watery places; and, if credit may be given to the reports of some authors, is of a disposition as gentle as its appearance is beautiful. It has even gained the title of monitor, salvaguardia, &c. from its pretended attachment to the human race, and it has been said that it warns mankind of the approach of the agitator by a loud and shrill whistle.

Cordylus, with either dentilicate or spiny scales on the body or tail, or both.

8. Lacerta pellona, is one of the middle-sized lizards; the total length being nearly two feet, and the length of the body and tail nearly equal. It is a native of Chili, where it is said to inhabit hollows under ground. It is covered with variously colored spots of yellow, blue, and black; the under parts are of a glossy yellowish-green; the tail long and verticillated by rows of rhomboid scales; and the head of this lizard has been said to be used by the Chilians for the purpose of a burnish.

9. Lacerta stellio, is remarkable for its unusually rough or hirsute appearance of its whole upper surface; both body, limbs, and tail, being covered with pointed scales, projecting here and there to a considerable distance beyond the surface, so that it appears foresticulated with spines; the tail is rather short, and verticillated with rows of rhomboid pointed scales. The general color of the animal is a pale blueish-brown, with a few deeper and lighter transverse variegations; its general length is about eight inches. It is a native of many parts of Africa.

Lizards proper, smooth, and the greater number furnished with broad square plates or scales on the abdomen.

10. Lacerta agilis, green lizard, is found in all the warmer parts of Europe, and seems pretty generally diffused over the ancient continent. It sometimes arrives at a very considerable size, measuring more than two feet to the extremity of the tail; its more general length, however, is from 10 to 15 inches. In its coloration it is the most beautiful of all the European lacerti, exhibiting a rich and varied mixture of darker and lighter green, interpersed with specks and marks of yellow, brown, blackish, and even sometimes red. The green lizard is found in various situations, in gardens, about warm walls, buildings, &c. and is an extremely active animal, often pursuing great crows, turned up grey, and escaping with great readiness from pursuit when disturbed. When taken, however, it is soon observed to become familiar, and may even be tamed to a certain degree; for which reason it is considered as a favourite animal in many of the warmer parts of Europe.

11. Lacerta bullaris, red-throat lizard. This, according to Catesby, is usually six inches long, and of a golden-green colour. It is common in Jamaica, frequenting hedges and trees, but is not seen in houses; when approached it swells its throat into a globular form, the protruded skin on that part appearing of a bright-red colour, which disappears in its withdrawn or contracted state; this action is supposed to be a kind of menace, in order to deter its enemy; but it is incapable of doing any mischief by its bite or otherwise. See Plate Nat. Hist. fig. 235.

Chameleons, with granulated skin, missile tongue, &c.

12. Lacerta chameleon. Few animals have been more admired by natural historians than the chameleon, which has been sometimes said to possess the power of changing its colour at pleasure, and of assimilating it to that of any particular object or situation. It must be received with very great limitations; the change of colour which the animal exhibits varying in degree according to circumstances of health, temperature of the weather, and many other causes; and consisting chiefly in a sort of alteration of shades from the natural greenish or blueish green of the skin into pale yellowish, with irregular spots or patches of dull red.

It is also to be observed, that the natural or usual colour of chameleons varies very considerably: some being much darker than others, and it has even been seen approaching to a blackish tinge. An occasional change of colour is likewise observable, though in a less striking degree, in some other lizards.

The general length of the chameleon, from the tip of the nose to the beginning of the tail, is about ten inches, and the tail is of nearly similar length, but the animal is found entire, and sometimes exceeds the length above mentioned. It is a creature of a harmless nature, and supports itself by feeding on insects; for which purpose the structure of the tongue is finely adapted, consisting of a long, slender body, furnished with a dilated and somewhat circular tip, by means of which the animal seizes insects with great ease, darting out its tongue in the manner of a weeverfish, and retrieving it instaneously with the prey secured on its tip. It can also support a long abstinence, and hence arose the popular idea of the chameleon being nourished by air alone. It is found in many parts of the world, and particularly in India and Africa. It is also sometimes seen in the warmer parts of Spain and Portugal.

The general or usual changes of colour in the chameleon, are from a blueish ash-colour, (its natural tinge) to a green and sometimes yellowish-green, and blackish green, with red. If the animal is exposed to a full sunshine, the unilluminated side generally appears, within the space of some minutes, of a pale yellow, with large roundish patches or spots of red-brown. On reversing the situation of the animal, the same change takes place in the opposite direction; the side which was before in the shade now becoming either brown or ash-colour, while the other side becomes yellow and red; but these changes are subject to much variety both as to intensity of colour and disposition of spots.

Besides the common chameleon, different races appear to exist, which are principally distinguished by their colour, and the more or less elevated state of the angular or crested part of the head. These, which Linnaeus was content to consider as varieties, are now raised to the dignity of species, and are so distinguished in the German edition of the Systema Naturae. Geckos, with granulated or tuberculated skin, lobated feet, and toe ameliated beneath.

13. Lacerta gecko. The gecko, said to be so named from the sound of its voice, which resembles the above word uttered in a shrill tone, is a native of many parts of Asia and Africa, as well as of some of the warmer regions of Europe. The middle-sized lizards, measuring, in general, about a foot in length, or rather more. It is of a thicker and stouter form than most other lizards, having a large and somewhat triangular head, covered with small scales, a wide mouth, large eyes, minute teeth, and a broad flat tongue. The limbs are of moderate length, and the feet are of a broader form than the rest of the genus.

The gecko inhabits obscure recesses, caverns, old walls, trees, &c. and is said to be chiefly on the approach of rain. It is considered as a poisonous nature, highly scurulative kind of fluid exuding from the corners of the feet, which remaining on the surface of fruit or any other edible substance is often productive of troublesome symptoms to those who happen to swallow it. From the peculiar structure of its feet, the gecko can adhere to smoothest or roughest surfaces. The general color of the animal is pale brown, with a few irregular daisy or bluish variegations; but in those insects in the warmer regions of the globe, this colour seems to be blended into a much more brilliant appearance.

14. Lacerta ambra. This remarkable species seems to have been first described by the Count de Cepedelle, who informed us that it appears in some degree to connect the chameleon, the gecko, and the water-newts; that the head, skin, and general form of the body, resembling those of the chameleon, the tail of the water-newts, being of a compressed form, though in a different manner (not vertically but horizontally flattened), while the feet resemble those of the gecko. The largest specimen examined by the author of this work is of about eight inches and six lines in length, of which the tail measured two inches and four lines. The colour of this animal is not constant or permanent, as in most lizards, but variable in the course of time successively different shades of red, yellow, green, and blue. This variation of colour is, however, confined to the upper surface of the animal; the lower always remaining of a bright yellow. These changes, we are
informed, have been observed in the living animal by Mons. Bruyeres, in his native country, and other naturalists. It is very uncommon, and where, though a harmless animal, it is held in great abhorrence by the natives, who consider it as a poisonous nature, and fly from it with precipitation; pretending that it deserts on their branches, and adheres with such force by its fringed membrane, that it cannot be separated from the skin without the assistance of a razor. The principal cause of this popular dread of the animal is, its habit of running down on its hinder part, towards the spectator, instead of attempting to escape; when discovered. Its chief residence is on the branches of trees, where it lives on insects, holding itself secure by coiling its tail, short as it is, half round the trunk of the tree. It is like most other lizards, adapted to rainy weather, when it moves with considerable agility, often springing from branch to branch. On the ground it walks but slowly, the fore legs being shorter than the hinder.

The skin, which raidous-like scales. 15. Lacerta sicarius, or official skin. The scind is one of the middle-sized or smaller lizards, of many of the warmer parts of the world. It abounds in Lybia, Syria, Egypt, and Arabia, frequenting moderately dry and sandy soils, and growing to the length of six or seven inches, or even sometimes more. The head of the scind is rather small than large, the body thick and round, the tail in general considerably shorter than the body. The whole animal is of a pale yellowish-brown colour, with a few brownish dots; and, when undisturbed, the flesh, particularly of the belly, was supposed to be diuretic, alexipharmic, restorative, and useful in leprous and many other cases; but whatever virtues it may possess when used fresh, a great deal of any advantage is lost when it is dried in its natural habitat.
LACTIC acid. If milk be kept for some time it becomes sour. The acid which then appears is this first examined by Scheele, and found by him to have peculiar properties. It is called lactic acid. In the whey of milk this acid is mixed with a little curd, some phosphat of lime, sugar of milk, and mucilage. All these must be separated before the acid can be examined. Scheele accomplished this by the following process:

Evaporate a quantity of sour whey to an eighth part, and then filtrate it: this separates the curdy parts. Saturate the liquid with lime-water, and the phosphat of not precipitates. Filtrate again, and dilute the liquid with three times its own bulk of water; then let fall into it oxalic acid, drop by drop, to precipitate the lime which has dissolved from the whey, and then add a very small quantity of lime-water, to see whether too much oxalic acid has been added. If there has, oxalat of lime immediately precipitates. Evaporate the solution to the consistence of heavy cream; then add a quantity of alcohol, and filtrate again; the acid passes through dissolved in the alcohol, but the sugar of milk and every other substance remain behind. Add to the solution a small quantity of water, and distil with a small heat, the alcohol passes over, and leaves behind the lactic acid dissolved in water.

This acid requires much concentration, when evaporated to dryness, it deliquesces again in the air. When distilled, water comes over first, then a weak acid resembling the tannic, then an empyreumatic oil mixed with more of the same acid, and, lastly, carbonic acid and carbonated hydrogen gas: there remains behind a small quantity of charcoal.

The combinations which this acid forms with alkalies, earths, and metallic oxides, are called lactats, which see.

All that is known concerning these salts are the following facts, ascertained by Scheele. When saturated with fixed alkalies, it gave salts, which were deliquescing and soluble in spirit of wine. It formed deliquescent salts with ammonia, with barytes, with lime, and alumina; but with magnesia it formed small crystals, which how ever at length deliquesced. When submitted to a mixture of hydrogen and tin, and various mixtures of metals and acids, the acid became more crystallized. It dissolved zinc and iron; and it produced with these metals hydrogen gas. Zine was the only metal with which it crystallized.

LACTIC, the lettere, a genus of the subg. of the former order, the eugenie class of plants, and in the natural order ranking under the 49th order, composite. The receptacle is naked; the calyx imbricated, cyllindrical, with a membraneous margin; the petals are simple, stipulated, or stalked. There are 11 species, most of which are plants of no use, and never cultivated but in botanic gardens for variety. That commonly cultivated in the kitchen-gardens is the common or garden lettuce, which includes the following varieties: 1. The common or garden lettuce. 2. Cabbage lettuce. 3. Silesia lettuce. 4. Dutch brown lettuce. 5. Aleppo, or spina lettuce. 6. Imperial lettuce. 7. Green capuchin lettuce. 8. Variegated or striped cos lettuce. 9. Black cos. 10. Red cos. 11. Red capuchin lettuce. 12. Roman lettuce. 13. Prince lettuce. 14. Royal lettuce. 15. Egyptian cos lettuce.

The first of these sorts is very common in all gardens, and is commonly sown for cutting very young, to mix with other salad herbs in spring; and the second, or cabbage lettuce, is only this demanded by culture. The first 40 should be sown in February, in an open situation; the others at three weeks distance; but the latter ones under cover, but not under the drippings of trees. The Silesia, imperial, royal, black, and upright cos lettuces, are first sown in the latter part of February or the beginning of March, on a warm light soil, and in an open situation: when the plants are come up, they must be thinned down to this acid, at any step, they will then require no further care than the keeping them clear of weeds; and the black cos, as it grows large, should have its leaves tied together to whiten the inner part. Succeeding crops of these should be sown in April, May, and June; and towards the latter part of August they may be sown for a winter crop, to be preserved under glasses, or in a bed arched over with hoops and covered with mats. The most valuable of all the English lettuces are the white cos, or the Versailles; and the Egyptian cos. The brown Dutch and the green Dutch are very hardy, and may be sown late under walls, where they will stand the winter, and be valuable when no others are to be had. The red capuchin, Roman, and prince lettuce, are very early kinds, and adorn the ornamental beds; as are also the those for the beauty of the spotted leaves.

The several sorts of garden lettuces are very wholesome, enlolicent, cooling salad herbes, easy of digestion, and since the lettuce has a peculiar property of soothing the belly. Most writers suppose that they have a narcotic quality; and indeed in many cases they contribute to procure rest; this they effect by soothing heat, and relying the appetite. The seeds are in the number of the four lesser cold seeds.

LAGUNAR. See Architecture.

LADDERS, scaling, in the military art, are used in scaling when a place is to be taken by surprise. They are made several ways: here we make them of flat staves, so that they may move about their pins, and shut like a parallel ruler, for conveniently carrying them: the French make them of several pieces, so as to be joined together, and to be made of any necessary length: sometimes they are made of single ropes, knotted at proper distances, with iron hooks at each end, one to fasten them upon the wall above, and another under, to which they are made with two ropes, and staves between them, to keep the ropes at a proper distance, and to tend upon. When they are used in the action of scaling walls, they ought to be rather too long, that they may be in charge only to the stoutest of the detachment. The soldiers should carry these ladders with the left-arm passed through the shoulder, taking care to hold them upright close to their sides, and very short below, to prevent any accident in leaping into the ditch.

The first rank of each division, provided with ladders should shout out with the rest at the signal, making resolution with their firelocks slung, to jump into the ditch: when they are arrived they should apply their ladders against the parapet, observing to place the ladder, rather than the middle of the curtine, because the enemy have less force there. Care must be taken to place the ladders within a foot of each other, and not to give them too much or too little slope, so that they may not be overturned or broken with the weight of the soldiers mounting upon them.

The ladders being applied, those who have carried them, and those who come after, should mount up, and rush upon the enemy sword in hand: if he who goes first happens to be overturned, the next should take care not to be thrown down by his comrade; but, on the contrary, immediately mount himself, so as not to give the enemy time to load his piece.

As the soldiers who mount first may be easily turned over, and their fall may cause the attack to fail, it would perhaps be right to protect their breasts with the fore parts of cutlasses; because if they can penetrate the rest may easily follow.

LADY'S slipper. See Cypripedium.

LAELIA, a genus of the monogynia or...
LAMINIA, in physiology, the thin plates of which many substances consist.

LAMIA, an order of plants, and in the natural method ranking with those of which the order is doubtful. The corolla is hexapetalous, or none; the calyx is penta- or monopetalous; the flowers are unisexual, and the seeds have a pulpily or casse. There are four species, natives of America. One of them, the apetal, or gum-wood, Dr. Wright informs us, is very common in the woodlands and copses of Jamaica, where it rises to a considerable height and thickness. Pieces of the trunk or branches, suspended in the heat of the sun, discharge a clear tarrentine or balsam, which concretes into a white resin, and which seems to be the same as gum sandarac. Poucke is made of it; and our author is of opinion that it might be useful in medicine like other gums of the same nature.

LAGERSTROEMIA, a genus of the monogynia order, in the polyandria class of plants. The corolla is hexapetalous, and curled; the calyx sepulcral, and campanulated; there are many stamens, and of these the six outer ones thicker than the rest, and longer than the flowers. There are four species, trees of the East Indies.

LAGOEIA, a genus of the monogynia order, in the petandria class of plants. The involucrum is universal and partial; the petals bisulcal; the seeds solitary, inferior. There is one species, wild cumin, an annual, of the Levant.

LAGUNEA, a genus of the class and order monadelpho polyandria. The calyx is simple, five-angled; style simple; stigma peltate; capsule five-celled, five-valved. There are three species, shrubs of the East Indies and Surinam.

LAGURUS, a genus of the digynia order, in the triandria class of plants, and in the natural method ranking under the fourth order, monandria. The calyx is hooded with a villous awn, the exterior petal of the corolla terminated by two awns, with a third on its back retorted. There is one species, a grass of the south of Europe.

LAKES, certain colours made by combining the colouring matter of cochineal, or of certain vegetables, with pure alumina, or with oxides of iron, &c.

LAM, the sovereign pontiff, or rather god, of the Asiatic Tartars, inhabiting the country of Barnabula. The lam is not only adored by the inhabitants of the country, but also by the kings of Tartary, who send rich presents, and go into pilgrimage to pay him adoration, calling him lam-cugiat, q. c. God the everlasting father of heaven. He is never to be seen but in a secret place of his palace, amidst a great number of lamps, sitting cross-legged upon a cushion, and adored all over with gold and precious stones; where, at a distance, they prostrate themselves before him, not being lawful for any to kiss even his feet. He is called the great lam, or lama of lamas, that is, priest of priests. And to persuade the people that he is immortal, the inferior priests, when he dies, substitute another in his stead, and so continue to cheat from generation to generation. These priests persuade the people that the lama was raised from death, in a hundred years ago, that he has lived ever since, and will continue to live for ever.

LAMINE, in physiology, the thin plates of which many substances consist.

LAGERSTRÖMIA, a genus of the monogyinia order, in the polyandria class of plants. The corolla is hexapetalous, and curled; the calyx is pentalamous, and campandulately; there are many stamens, and of these the six outer ones thicker than the rest, and longer than the flowers. There are four species, trees of the East Indies.

LAGOEIA, a genus of the monogyinia order, in the petandria class of plants. The involucrum is universal and partial; the petals bisulcal; the seeds solitary, inferior. There is one species, wild cumin, an annual, of the Levant.

LAMP BLACK, among colouren. See Black.

LAMPREY. See Petromyzon.

LAMPYRIS, glow-worm, a genus of insects of the order Coleoptera: the generic character is: wing-cases longish, flexible; thorax flat, semi-serrulcral, concealing and surrounding the head; abdomen with the sides pleated into papillae; female (in most species) wingless. The lampyris noctuica, or common glow-worm, is a highly curious and interesting animal. It is seen during the summer months as late as the close of Aug., if the season is mild, on dry banks, about woods, pastures, and hedgerows, exhibiting, as soon as the dew is off, the most beautiful and luminous phosphorescent splendour, in form of a round spot of considerable size. The animal itself, which is the female insect, measures about three-quarters of an inch in length, and is of a dull earthy brown colour on the upper parts, and beneath, more or less tinged with rose-colour, with the two or three last joints of the body of a pale or whitish sulphur-colour. It is from these parts that the phosphoric light arises; the exuviae are of a yellowish colour, with a very slight cast of green; the body, exclusive of the thorax, consists of ten joints or divisions. The larva, pupa, and complete female insect, scarcely differ perceptibly from each other in general appearance, but the phosphoric light is strongest in the complete animal. The glow-worm is a slow-moving insect, and in its manner of walking frequently seems to drag itself on by short and slight efforts. The male is smaller than the female, and is provided both with wings and wing sheaths; and it is but rarely seen.

It is certain that in some species of this genus the male, as well as the female, is luminous; as in the lampyris Italica, which seems to be a native of our own island also, though less common here than in the warmer parts of Europe. Abdorvanus describes the wing-cases as having the wings of a dusky colour, and at the end of the body two brilliant fiery spots like the flame of sulphur. See Plate Nat. Hist. figs. 238, 239.

In the Philosophical Transactions for the year 1684, we find a paper by a Mr. Walter, describing the English flying glow-worm as of a dark colour, with the tail part very luminous. He maintains that both male and female of this species are winged, and that the female is larger than the male: the light of this insect was very vivid, so as to be plainly perceived even when a candle was in the room. Mr. Walter observed this species at Northaw, in Hertfordshire. From the figure given by this writer it appears to be about half an inch in length, which is much smaller than the common female glow-worm.

In Italy this flying glow-worm is extremely plentiful; and we are informed by Dr. Smith and other travellers, that it is a very common practice for the ladies to stick them by way of ornament in different parts of their head-dress during the evening hours.

The common or wingless glow-worm may be very successfully kept, if properly supplied with meadow turf, grass, moss, &c. for a considerable length of time; and as soon as the evening commences, will regularly exhibit its beautiful effulgence, illuminating every object within a small space around it, and sometimes the light is so vivid as to be perceived through the glass by which it is kept. This insect deposits its eggs, which are small and yellowish, on the leaves of grass, &c. There are 13 species of the lampyris.

LAND, in the sea language, makes part of several compound terms: thus land-lock'd, or to lay the land, is just to lose sight of it. Land-locked, is when land lies all round the ship, so that no point of the compass is open to the sea; if she is at anchor in such a place, she is said to be land-locked, and is therefore concluded to ride safe from the violence of winds and tides. Land-marks, any mountain, rock, steepel, tree, &c. that may serve to make the land known at sea. Land is that in, a term used to signify that another point of land hinders the sight of that the ship came from. Land to, the ship lies land to, that is, she is so far from shore that it can only be just discerned.

LAND-TAX. See Taxation.

Landscape. See Painting.

LAST branch of the public revenue, the origin of which may be traced to the fines or commutations for military service, levied during the feudal system under the name of scutages. These are supposed to have been the first more arbitrary compositions, as the king and the persons liable could agree; but the practice having been much abused, it was declared by Magna Charta, and afterwards repeatedly confirmed by acts of parliament, that no scutage should be imposed without the consent of the great men and commons, in parliament assembled. This tax was sometimes exacted under the name of hydage, or carrage; but taxes on land came afterwards to be generally denominated subsidies, or assessments. During the Commonwealth, taxes on land were levied by monthly assessments; and commissioners were appointed in each county for rating the land, and assessing the rates according to the exigencies of the times, from 35,000l. to 120,000l. a month; the assessments in Scotland were commonly 6000l. but sometimes 1000l. a month; in Ireland the rate of raising money was so prodigiously high, that the great body of money was found so productive, that, with some little variations, it has under the denomination of land-tax ever since formed an important branch of the revenue.

The land-tax, till lately, differed from all the other branches of the public revenue (except part of the duties on malt), in being imposed annually, whereas other taxes have been granted either for a term of years, or for more commonly of late years, for ever; but though granted for only one year at a time, it has been regularly continued from year to year since the Revolution, having never been wholly taken off; but it has varied with respect to the rate at which it has been imposed, having been usually reduced during peace, and increased again in time of war, to answer, in part, the increased expenditure. In 1683 it was first raised to four shillings in the pound, but twice given in the following year, and according to which it has continued to be raised to the present time, at the following rates:

In 1698 and 1699, at 3s.
1700, at 2s.
1702 to 1712, at 3s.
1713 to 1715, at 2s.
1719, at 4s.
1717 to 1721, at 3s.
1722 to 1726, at 2s.
1727, at 3s.
1728 and 1729, at 3s.
1730 and 1731, at 2s.
1732 and 1733, at 1s.
1734 to 1739, at 2s.
1740, at 3s.
1750 to 1752, at 3s.
1753 to 1755, at 2s.
1756 to 1766, at 4s.
1767 to 1770, at 3s.
1771, at 4s.
1772 to 1775, at 3s.
1776 to 1798, at 4s.

The sums to be raised at 4s. in the pound were stated, in the annual act, at 1,999,657l. 7s. 10d. for England, and 47,954l. 1s. 2d. for Scotland, making together 2,037,607l. 9s. 6d.; and upon credit of this annual sum was annually borrowed of the Bank in anticipation of the tax, for which sum exchequer-bills were given them, which were to be discharged out of the produce of the tax as it came in; but the full amount of the assessment was seldom, if ever, collected, so that the nett payments into the exchequer always fell short of the sum borrowed on the credit thereof, exclusive of interest on the bills; and the deficiency was made good out of the supplies for the next year.

In 1795 the current value of the public funds having been unusually depressed for some time past, and apprehensions being entertained that the further increase of the funded debt would be attended with peculiar inconvenience, unless some mode was discovered of counteracting its effects, a project was adopted of offering the land-tax for redemption or sale. With this view an act was passed, creating a perpetual annual tax, from 25th March, 1759; and being thus converted into a permanent annuity, it was offered for sale to the proprietors of the lands upon which it was charged; or if they declined it, to any other person who chose to become a purchaser. In the first case it was considered as a redemption of the tax, the estate becoming in future wholly free from it; in the latter case the purchaser became entitled to receive the land-tax regularly from the receiver-general, half-yearly, on the 16th of March and 20th of September in every year. The consideration to be given in either case was not to be in money, but stock, either in the three per cent. consols, or three per cent. reduced, to be transferred to the commissioners for the reduction of the national debt. The quantity of stock to be transferred for redemption of the tax by persons interested in the land on which it was charged, was so much capital as yielded an annuity or dividend exceeding the amount of the tax to be redeemed by one-tenth part thereof; and the stock thus transferred for purchase of the tax by persons not interested in the land, was so much capital as yielded an annuity or dividend exceeding the tax to be purchased by one-fifth part thereof. Thus
the amount of three per cent. stock to be transferred for 10s. per annum, was 300l. 13s. 4d. for redemption, or 400l. for purchase.

This scheme was adopted with the view of facilitating the raising of money on loan, by absorbing a large extent of land tax, and thus raising the current price; while at the same time it would be attended with an increase of revenue. This at least was the avowed object of the measure, which was estimated in its consequences of raising or taking out of the market about 80,000,000l. of stock; the advantages offered by it were however, by no means such as to induce a general approval of it, many persons subject to the tax declined redeeming it, and few were inclined to become purchasers. The period first limited was several times extended, but the plan succeeded very imperfectly, and on the 1st of February, 1833, the total amount of 2 per cent. stock, which had been transferred for the redemption of land tax, was only 21,794,307l. 17s. 3d.

LANERIA, a genus of the hexandria monogynia class and order. The corolla is superior, woolly, the caps. three-celled. There is one species, a herb of the Cape.

LANGAYA, a genus of serpents; the generic character is, abdominal scales; caudal rings; terminal scales.

Langaya nasuta, snouted langaya. The genus langaya, consisting of a single species only, differs from all the rest of the serpent tribe in having the upper part or beginning of the tail marked into complete rings or circular divisions resembling those on the body of the amphisbaena, while the extreme or terminal part is covered with small scales, as in the genus anguis.

The langaya nasuta, or long-snouted langaya, is in length about two feet eight inches, and its greatest diameter about seven lines; the head is covered with small scales, but the snout, which is extremely long and sharp, projecting to a considerable distance beyond the lower jaw, is covered with very small scales; the teeth, in shape and disposition resemble those of the snapping-turtles. The natives of Madagascar are said to hold the langaya in great dread, considering it as a highly poisonous serpent.

LANGUED, in heraldry, expresses such animals whose tongue appearing out of the mouth, is borne of a different colour from that of the body.

LANIUS, the shrike, or butcher-bird; a genus belonging to the order of accipitres, the characters of which are these: the beak is somewhat straight, with a tooth on each side towards the apex, and naked at the base; and the tongue is lacertine.

1. The excubitor, great cicerine shrike, or greater butcher-bird, is in length 10 inches. The plumage on the upper parts is of a pale ash-colour; the under parts, white; through the eyes there is a black ring; the scapulars are white; the base of the greater quills is white, the rest black. The method of killing its prey is singular, and its manner of devouring it less extraordinary: small birds it will seize by the throat, and, without an annul tax, probably is the reason the Germans also call this bird wurchen, or the suffocating angel. It feeds on small birds, young nestlings, beetles, and caterpillars. When it has killed the prey, it fixes them on some thorn, and, when thus spirited, pulls them to pieces with its bill. Where they are in a cavity of a cliff, or they will often treat their food in much the same manner, sticking it against the wires before they devour it. This bird inhabits many parts of Europe and North America. The female has its nest with hair and moss, linting it with wool and gossamer, and lays six eggs, about as big as those of a thrush, of a dull olive-green, spotted at the thickest end with black. In spring and summer it imitates the voices of other birds, by way of decoying them within reach, that it may destroy them; but beyond this the natural note is the same throughout all seasons. In countries where they are plentiful, the husbandmen value them, on supposition of their destroying rats, mice, and other vermin. They are supposed to live five or six years; and are often trained up for catching small birds in Russia.

2. The colibrirl, or lesser butcher-bird, is seven inches and a half in length. This bird is much more common than the former species. Mr. Latham suspects its being a bird of passage, never having seen it in winter. It lays six white eggs, marked with a rufous brown circle, within forty-eight hours. The nest is generally in a hedge or low bush, near which it is said, no small bird chooses to build; for it not only feeds on insects, but also on the young of other birds in the nest, taking hold of them by the neck, and strangling them, beginning to eat them first at the brain and eyes. It is fond of grasshoppers and beetles than of other insects, which it eats by morsels, and when satisfied, shakes the remains of the insects into the grass, which does the same against the wires of it, like the former species.

3. The infaustus, or rock shrike, is in length seven inches and three quarters. The bill is about an inch long, and blackish; the head and neck are of a dark ash-colour, marked with small rufous spots; the upper part of the back is a dark brown; the lower much paler, inclining to ash, especially towards the tail; the sides of the body, inclined with white, are covered with pale margins; the breast, and under parts of the body, are orange, marked with small spots, some white and others brown. This species is met with in many parts of Europe, from Sweden on the north, to Portugal on the south; and is found in some parts of Germany, the Alpine mountains, those of Tyrol, and such-like places. The manners of this bird seem disputatious; it has an agreeable note of its own, approaching to that of the hedge sparrow; and will also learn to imitate that of others. It makes the nest among the holes of the rocks, &c., hiding it with great art; and lays three or four eggs, feeding the young with worms and insects, on which it also feeds itself. It may be taken young from the nest, and brought up as the nightingale.

4. The autumnalis, or white-wreathed shrike, is about the size of a common thrush. Its bill is pale; the upper parts of the body are grey; the under rufipennis; from the eyes to the hind head there passes a whitish line, composed of numerous white feathers, rendering it truly characteristic; the wings are rounded; the quills brownish, with grey edges, which are more numerous and slender brown lines; the tail is rounded, brown, and crossed with numerous bars of darker brown; the legs are pale. This elegant species inhabits China, where it is known by the name of whomgo. It may be observed, among others, in the natural watches, where the white line seems to encompass the back part of the head like a wreath.

5. The tyrannus, or tyrant shrike, is about the size of a thrush. Its bill is a blackish brown, beset with bristles at the base; the eyes are brown; the upper parts of the plumage grey brown; the under white; the bron t includes ash-colour; the head is blackish on the upper part; the base of the feathers on that part in the male is orange, but seldom visible except it excites the terrors, when there appears a streak of orange down the middle of the crown. It inhabits Virginia. There is a variety which inhabits St. Domingo and Jamaica. These birds are called darwin, pipit, or spurin, from their cry, which resembles those words. All authors agree in the manners of these birds, which are so curious a great degree while the hen is sitting; no bird whatever dare approach their nest, they will attack the first which comes near, without reserve, and usually come off conquerors.

Many species of this genus are found in Ceylon, and other hot countries, as the linus varius. See Plate Nat. Hist. fig. 243.

LANNIERS, or Laniiacae, in a small, are small groups reared into the dead-plant's head, the eyes of all grounds, either to slacken them or to set them fast; the stays of all masts are also set fast by lanniers.

LANTEA, or Indian sage, a genus of the angiospermia order, in the dianthusea class of plants, and as in the natural method ranking under the 40th order, personatae. The calyx is indistinctly quadridentated; the stigma broken, and turned back like a hoop; the fruit is a plan with a buliberal kernel. There are 9 species, consisting of shrubby exotics from Africa and America for the greenhouse or stove, growing to the height of a yard or two, and adorned with oblong, oval, and roundish simple leaves, with numerous, tubular, four-lobed, whitish, or yellow, with some tinted flowers of different colours. They may be propagated either by seeds or cuttings. 1. The camara, or wild sage, is remarkable for the beauty of its flowers, which are yellow, tinged with red. 2. The involucrata, or white-wreathed ash-coloured leaves and a most agreeable smell. They are both natives of the West Indies, the former growing wild among the bushes, and the latter being found near the sea. Their leaves, particularly those of the seaside sage, are used by the black people in teas for colds and complaints of the stomach.

3. The acteola is a beautiful stove plant, remarkable for its flowers changing from yellow to red. See Plate Nat. Hist. fig. 243.

LANTERN, Magic, an optical machine, whereby little painted images are represented so much magnified, as to be accounted the effect of magic by the ignorant. See Optics.

LANTERN, See Architecture.

LAPIDARY. There are various machines employed in the cutting of precious stones, according to the quality: the diamond, which is extremely hard, is cut on a wheel of soft steel, turned by a mill, with diamond-dust, tempered with olive-oil, which also serves to polish it. The Oriental ruby, sapphire, and topaz, are
cut on a copper wheel with diamond-dust, tempered with olive-oil, and are polished on a third wheel with tripoli, or soapstone. The hyacinth, emerald, ametyst, garnets, agates, and other stones, not of an equal degree of hardness with the other, are cut on a leaden wheel with small and water, and polished on a tin wheel with tripoli, or soapstone. The turquoises of the old and new rock, girasol, and opal, are cut and polished on a wooden wheel with tripoli also.

LAPS, in general, is used to denote a stone of any kind. See Mineralogy.

Lapis calcitrix, a genus of stones consisting of silica, a small quantity of aluminium, with about one-tenth of lime, and a slight trace of oxide of iron: hard, lustrous, shining within, breaking into fragments with sharp edges; compact, not mouldering in the air; of a more or less perfectly conchoidal texture; never opaque, tough, admitting of a high polish, and generally of a common form; not melting before the blowpipe. See Plate Nat. Hist. fig. 241.

LAPLISIA, or sea-hare, a genus of marine inlets belonging to the order of vermec mollusca. See Plate. The body is covered with a shield-like mantle. It has a shield-like membrane on the back, a lateral pore on the right side, the anus on the extremity of the back, with four feelers resembling ears. The figure represents the deplatis minor, which grows to the size of a man and a half in length, and to more than an inch in diameter; its body approaches to an oval figure, and is soft, punctured, of a kind of gelatinous substance, and of a pale lead-colour; from the larger extremity there is a four oblong and thick prominence; these are the tentacles; two of them stand nearly erect, two are thrown backward. It is not uncommon about our shores, especially off Anglesea. It causes, by its poisonous juice, the hair to fall off the hands of those that touch it; and is so extremely fetic as to create sickness at the stomach. The major, or greater sea-hare, grows to the length of eight inches.

LAPPAGO, a genus of the trinaria digerens class and order. There is one species, a grass.

LAPSANA, nipplewort, a genus of the polygonum aquatilis class, in the syngecynia class of plants, and in the natural method polyburnthae: the receptacle is naked; the calyx calculated, with all the inferior scales calcuated or finely channelled. There are five species, which grow commonly as weeds by the sides of ditches. The young leaves of the common kind, called dock-cresses, have the taste of radishes, and are eaten raw at Constantinople as a salad. In some parts of England the common people boil them as greens, but they have a bitter and disagreeable taste.

LAPSE, the omission of a patron to present to a church, within six months after voidable; by which neglect title is given to the ordinary to collate to such church; and in such cases, the patronage devolves from the patron to the bishop, from the bishop to the archbishop, and from the archbishop to the king. A donative does not go in lapse; but the ordinary may compel the patron by ecclesiastical process to fill up the vacancy. But if the donative has been augmented by the governors of queen Anne's bounty, it will lapse in like manner as a representative living.

LAPSED LEGACY, is where the legatee dies before the testator; or where a legacy is given upon a future contingency, and the legatee dies before that contingency happens. As if a legacy is given to a person who attains the age of 21 years, and the legatee dies before that age; in this case the legacy is a lost or lapsed legacy, and shall sink into the residuum of the personal estate. 2 Black. 613.

LABBOARD, among seamen, the left hand side of the ship, when you stand with your face towards the head.

LARCENY, is the felonious and fraudulent taking away the personal goods of another; which goods, if they are above the value of 12d. it is called grand larceny; if of that value or under, it is petit larceny; which two species are distinguished in their punishment, but not otherwise. 4 Black. 229.

The mind only makes the taking of another's goods to be felony, or a bare trespass only; but as the variety of circumstances is so great, and the complications thereof so mingled, it is impossible to prescribe all the different cases in which a felonious intenion is or the contrary; it must therefore be left to the due and attentive consideration of the judge and jury, wherein the best rule is, in doubtful matters, rather to incline to acquittal, than in general it may be observed, that the ordinary discovery of a felonious intent is, if the party do it secretly, or being charged with the goods deny it. 11 H. 399.

As all felony includes trespass, every indictment must have the words feloniously took, as well as carried away; whence it follows, that if the party be guilty of no trespass in taking the goods, he cannot be guilty of felony in carrying them away. 1 Haw. 89.

With respect to what shall be considered a sufficient carrying away, to constitute the offence of larceny; it seems that any the least removing of the thing taken, from the place where it was before, is sufficient for this purpose, though it be not quite carried off. 1 Haw. 93.

As grand larceny is a felonious and fraudulent taking of the more personal goods of another above the value of 12d. so it is petit larceny if the stolen thing is not of the value of 12d. or under. In the several other particulars above-mentioned, petit larceny agrees with grand larceny. 1 Haw. 83.

In petit larceny there can be no accessories either before or after. 1 H. 1. 530.

Larceny from the person. If larceny from the person be done privily without his knowledge, by picking of pockets or otherwise, it is excluded from the benefit of clergy by 5 Eliz. c. 4, provided the thing stolen be above the value of 12d. 2 H. 11. 330.

But if done openly and avowedly before it, it is within the benefit of clergy. 1 Haw. 97.

Larceny from the house. Every person who shall be convicted of the feloniously taking away in the day-time, any money or goods of the value of 5s. in any dwelling-house, or out-house thereto belonging, and used to and with the same, though no person be there in, shall be guilty of the felony, without benefit of clergy. 5 Eliz. c. 15.

Receiving stolen goods. Any person who shall buy or receive any stolen goods, knowing them to be stolen; or shall receive, harbour, or conceal any felon or thieves, knowing them to be so; shall be guilty of felony to the felony; and being convicted on the testimony of one witness, shall suffer death as a felon convict; but he shall be entitled to his clergy. 5 Anne c. 31.

But if any person receiving or buying stolen goods, knowing them to be stolen, may be transported for fourteen years. 4 Geo. 1. c. 11.

Where the principal felon is found guilty to the value of the thing stolen of petit larceny only, the receiver, knowing the goods to have been stolen, cannot be transported for fourteen years, and ought not to be put upon his trial; for the acts which made receivers of stolen goods knowingly, accessories to the felony, must be understood to make them accessories in such cases only, where by law an accessory may be; and there can be no accessory to petit larceny. 33 Geo. c. 74.

Every person who shall apprehend any one guilty of breaking open houses in a felonious manner, or of privately and feloniously stealing goods, wares, or merchandise, of the value of 5s. in any shop, warehouse, storehouse, or stable, though it is not broken open, and if no person is therein to put in fear, and shall prosecute him to conviction, shall have a certificate without fee, under the hand of the judge, certifying such conviction, and within what parish or place the felony was committed, and also that such felon was discovered and taken, or discovered or taken, by the person so discovering or apprehending; and if any dispute arise between several persons so discovering, or apprehending, the judge shall appoint the certificate into so many shares, to be divided among the persons concerned, as to him shall seem just and reasonable. Leishe's Cro. Law, 307. See Jurors.

LARK. See Alauda.

LARKSPUR. See Delphinium.

LARVA, in natural history, a name given by Linneus to insects in that state, called by the ancients erucia, or caterpillars.

LARUS, the name in the order of anseres, the characters of which are: the bill is straight, culverted, a little crooked at the point, and without teeth; the inferior mandible is gibbous below the cusp; the rostra are thin, situated in the middle of the beak. The different species are principally distinguished by their colour. The most remarkable are:

1. The marins, or black-backed gull, in length 29 inches, breadth five feet nine. The bill is very strong and thick, and almost four inches long; the colour a pale yellow; the head, neck, whole under-side, tail, and lower part of the back, are white; the upper part of the back and wings are black; the quills-leathers tip with white; the legs of a pale flesh-colour. It inhabits several parts of England, and breeds on the highest cliffs. The egg is blunt at each end, of a dusky olive-colour, quite black at the greater end, and the rest of it thinly marked with dusky spots. It is also common on most of the northern coasts of Europe. It frequents Greenland, but chiefly inhabits the distant islands of the Arctic sea. We may, placing them on the heads of dicing which the birds leave there from time to time. It is said to attack other birds, and to be particularly an
enemy to the eider duck. It very greedily devours carrion, though its most general food is fish. It is common also in America, as low as South Carolina, where it is called the old-wife.

2. The eustria, or Skua gull, is in length two feet; the extent four feet and a half; the weight three pounds; the feathers on the head, neck, back, scapulars, and coverts of the wings are of a deep brown, marked with a rust-colour (brightest in the male). The breast, belly, and vent are ferruginous, tinged with ash-colour. This bird inhabits Norway, the Ferroo isles, Shetland, and the noted rock Foula a little west of them. It is also a native of the South Sea. It is the most formidable of the gulls; its prey being not only fish, but what is wonderful in a seabird, all the lesser sort of water-fowl, such as teal, &c. Mr. Schrotter, a surgeon in the Ferroo isles, relates that it likewise preys on ducks, poultry, and even young lambs.

The natives of the Orkneys are often very rudely treated by them while they are attending their sheep on the hills, and are obliged to guard their heads by holding up their sticks, or the heads of the birds themselves. In Foula it is a privileged bird, because it defends the flocks from the eagle, which it beats and pursues with great fury; so that even rapacious bird seldom ventures near its quarters.

3. The parasitic, or dun-gunter, is in length 21 inches; the upper parts of the body, wings, and tail, are black; the base of the quills white on the inner webs; and the middle feathers of the tail near four inches longer than the rest. This is a very small species, and very common in the Hebrides, where it breeds on heaths. It comes in May, and retires in August; and if disturbed flies about like the gawpin, but soon alights. It is also found in the Orkneys; and on the coasts of Yorkshire, where it is called the lesser. This bird does not often swim, and flies generally in a slow manner, except in pursuit of other birds, when it will often fly swiftly. It runs along seas in flocks, in order to make them disgorge the fish or other food which this common plunderer greedily catches.

4. The cans, or common gull, is in length 16 or 17 inches; the weight one pound. The bill is yellow; the head, neck, and under parts of the body and tail are white; the back and wings pale-grey. It is a tame species, and may be seen by hundreds on the shores of the Thames and other rivers, in the winter and spring, at low tides, picking up the various worms and small fish left by the tides; and will often follow the plough in the fields contiguous, for the sake of worms and insects which are turned up; particularly the cockle-chatter or dorbet in its larva state, which it joins with the rooks in devouring most greedily.

5. The tridactylus, or tarrock, is in length 14 inches, breadth 30; weight seven ounces. The head, neck, and under parts, are white; near each ear, and under the throat, there is a black spot; and at the hind part of the neck a crescent of black; the back and scapulars are blueish-grey; the wing-covers dusky edged with grey; the quills and tips white. This species breeds in Scotland, and inhabits other parts of northern Europe, quite to Iceland and Spitzbergen. It is observed frequently to attend the whales and seals, for the sake of the fish which the last drive before them into the shallows, when these birds dart into the water suddenly, and make them their prey.

6. The ridibundus, pewit, or black-headed gull, is in length 15 inches, breadth three feet; the quills black, and wing-tips and neck are of an ash-colour; the neck, all the under parts, and tail, are white; the first ten quills are white, margined, and more or less tipped with black; the others of an ash-colour. This species breeds on the shores of some of our rivers; but full as often in the inland fens of Lincolnshire, Cambridgeshire, and other parts of England. They make their nest on the ground, with rushes, dead grass, &c. and lay three eggs of a greenish-brown, marked with red-brown blotches. After the breeding season, they again disperse to the coast.

The young birds in the neighbourhood of the Thames are thought good eating, and are called the red legs. They were formerly more numerous; but numbers were annually taken and fattened for the table. Whitehock, in his annals, mentions a piece of ground near Portsmouth, which produced to the owner 40 particulars a year by the sale of pewits, with the species of the sea. It is remarkable that in old times the gulls that in old times were admitted to the noblemen's tables. The note of these gulls is like a hoarse laugh.

7. The trismis, or laughing gull, is in length 18 inches, breadth three feet; it is found in Russia on the river Don, particularly about Tschercask. The note resembles a coarse laugh, whence the name of the bird. It is met with also in different parts of the coasts of America, and is very numerous in the Bahama islands.

There are 14 or 15 other species of this genus. See Plate Nat. Hist. fig. 242.

LARYNX. See Anatomy.

LASH, or LACE, in the sea language, signifies to bind and make fast.

LASERITIUM, lusor-curtus, a genus of the plant class of plants, and in the natural method ranking under the 45th order, umbellata. The fruit is oblong, with eight membranaceous angles; the petals, reflexed, emarginated, and patent. There are more species which are all remarkable for their beauty, so are only preserved in botanic gardens for the sake of variety.

LATOPISTOMA, a genus of the class and order tetrandria monogynia; the calyx is very short, five-petalled; corolla funnel-form, foxtail-cleft; caps. orbicular, one-celled, two-seed.

There is one species, a shrub of Guiana.

LASKETS, small lines, like loops, sewed to the bonnets of drabbers of a ship, to lash or lace the bonnets, the courses, or the drabbers to the bonnets.

LASKING, at sea, is much the same with going large, or veering, that is, going with a quarterly wind.

LAST, in general, signifies the burden or load of a ship. It signifies also a certain measure of fish, corn, wool, leather, &c. A list of codfish, whiting, herrings, and ashes for soap, is 12 barrels; of corn or rapsessed, 10 barrels, of red-herrings 20 cedes; of hides 12 dozen; of leather 20 dickers; of pitch and tar 14 barrels; of wool 12 sacks; of stock-fish 1000; of flux or feathers 1700 pounds.
screw in E, the conical end F may at any time be made to fit its socket; the punch of G has a cylindrical hole through its top to receive the polished pointed rod d, which is moved by the screw c, and fixed by the screw j; the whole punch is fixed on the triangular piece P, which bears the point of which, a, b, c, are put through holes b, in the bottom of the punch under the bar. The whole is fixed by the screw c pressing against it; by this means the punch can be taken off the bar without first taking off the standard I, as in the common lathes; and the triangular bar is found to be far preferable to the double rectangular one in common use.

The rest J in a similar contrivance; it is in 3 pieces; see figs. 141, 141, 142. Fig. 141 is the piece, the opening (a, b, c) in which is laid upon the bar H, fig. 138.; the four legs d d d d of fig. 142. are then put upon the bar (into the recesses in fig. 141. which are made to receive them), so that the notches in d d are held by the bar. Fig. 143: the punch heads e, f, in fig. 140. are then slid into the notches in the top of d d d d, to keep the whole together; the groove i is to receive a corresponding piece on e, fig. 140., to which it is fixed, and fig. 140. has a cover, to keep the chips out of the grooves. It is plain, that by tightening the screw b in the bottom of figs. 138. and 142., the whole will be fixed and prevented from sliding along the bar H, and fig. 140. from sliding in a direction perpendicular to the bar; the piece l, on which the tool is laid, can be raised or lowered at pleasure, and fixed by the screw m. On the end n of the spindle P, figs. 138. and 139., is mounted a self-adjusting hand-mandril, for holding any kind of work which is to be turned (fig. 144.). As the female screw to receive the screw n, fig. 138.; near the bottom of the screw A is another BB, which is prevented from moving by a bar attached to the mandril, and is used for holding any kind of work which is to be turned (fig. 144.). As the female screw to receive the screw n, fig. 138.; near the bottom of the screw A is another BB, which is prevented from moving by a bar attached to the mandril, and is used for holding any kind of work which is to be turned (fig. 144.). As the female screw to receive the screw n, fig. 138.; near the bottom of the screw A is another BB, which is prevented from moving by a bar attached to the mandril, and is used for holding any kind of work which is to be turned (fig. 144.). As the female screw to receive the screw n, fig. 138.; near the bottom of the screw A is another BB, which is prevented from moving by a bar attached to the mandril, and is used for holding any kind of work which is to be turned (fig. 144.). As the female screw to receive the screw n, fig. 138.; near the bottom of the screw A is another BB, which is prevented from moving by a bar attached to the mandril, and is used for holding any kind of work which is to be turned (fig. 144.). As the female screw to receive the screw n, fig. 138.; near the bottom of the screw A is another BB, which is prevented from moving by a bar attached to the mandril, and is used for holding any kind of work which is to be turned (fig. 144.). As the female screw to receive the screw n, fig. 138.; near the bottom of the screw A is another BB, which is prevented from moving by a bar attached to the mandril, and is used for holding any kind of work which is to be turned (fig. 144.). As the female screw to receive the screw n, fig. 138.; near the bottom of the screw A is another BB, which is prevented from moving by a bar attached to the mandril, and is used for holding any kind of work which is to be turned (fig. 144.). As the female screw to receive the screw n, fig. 138.; near the bottom of the screw A is another BB, which is prevented from moving by a bar attached to the mandril, and is used for holding any kind of work which is to be turned (fig. 144.). As the female screw to receive the screw n, fig. 138.; near the bottom of the screw A is another BB, which is prevented from moving by a bar attached to the mandril, and is used for holding any kind of work which is to be turned (fig. 144.). As the female screw to receive the screw n, fig. 138.; near the bottom of the screw A is another BB, which is prevented from moving by a bar attached to the mandril, and is used for holding any kind of work which is to be turned (fig. 144.). As the female screw to receive the screw n, fig. 138.; near the bottom of the screw A is another BB, which is prevented from moving by a bar attached to the mandril, and is used for holding any kind of work which is to be turned (fig. 144.). As the female screw to receive the screw n, fig. 138.; near the bottom of the screw A is another BB, which is prevented from moving by a bar attached to the mandril, and is used for holding any kind of work which is to be turned (fig. 144.). As the female screw to receive the screw n, fig. 138.; near the bottom of the screw A is another BB, which is prevented from moving by a bar attached to the mandril, and is used for holding any kind of work which is to be turned (fig. 144.). As the female screw to receive the screw n, fig. 138.; near the bottom of the screw A is another BB, which is prevented from moving by a bar attached to the mandril, and is used for holding any kind of work which is to be turned (fig. 144.). As the female screw to receive the screw n, fig. 138.; near the bottom of the screw A is another BB, which is prevented from moving by a bar attached to the mandril, and is used for holding any kind of work which is to be turned (fig. 144.). As the female screw to receive the screw n, fig. 138.; near the bottom of the screw A is another BB, which is prevented from moving by a bar attached to the mandril, and is used for holding any kind of work which is to be turned (fig. 144.). As the female screw to receive the screw n, fig. 138.; near the bottom of the screw A is another BB, which is prevented from moving by a bar attached to the mandril, and is used for holding any kind of work which is to be turned (fig. 144.). As the female screw to receive the screw n, fig. 138.; near the bottom of the screw A is another BB, which is prevented from moving by a bar attached to the mandril, and is used for holding any kind of work which is to be turned (fig. 144.). As the female screw to receive the screw n, fig. 138.; near the bottom of the screw A is another BB, which is prevented from moving by a bar attached to the mandril, and is used for holding any kind of work which is to be turned (fig. 144.). As the female screw to receive the screw n, fig. 138.; near the bottom of the screw A is another BB, which is prevented from moving by a bar attached to the mandril, and is used for holding any kind of work which is to be turned (fig. 144.). As the female screw to receive the screw n, fig. 138.; near the bottom of the screw A is another BB, which is prevented from moving by a bar attached to the mandril, and is used for holding any kind of work which is to be turned (fig. 144.). As the female screw to receive the screw n, fig. 138.; near the bottom of the screw A is another BB, which is prevented from moving by a bar attached to the mandril, and is used for holding any kind of work which is to be turned (fig. 144.). As the female screw to receive the screw n, fig. 138.; near the bottom of the screw A is another BB, which is prevented from moving by a bar attached to the mandril, and is used for holding any kind of work which is to be turned (fig. 144.). As the female screw to receive the screw n, fig. 138.; near the bottom of the screw A is another BB, which is prevented from moving by a bar attached to the mandril, and is used for holding any kind of work which is to be turned (fig. 144.). As the female screw to receive the screw n, fig. 138.; near the bottom of the screw A is another BB, which is prevented from moving by a bar attached to the mandril, and is used for holding any kind of work which is to be turned (fig. 144.). As the female screw to receive the screw n, fig. 138.; near the bottom of the screw A is another BB, which is prevented from moving by a bar attached to the man
LAVATERA, a genus of the polygonum order, in the polyneurina class of plants, and in the natural method ranking under the 37th order, commeliniana. The exterior calyx is double and trifid; the anthers and seeds are very many and mosaicous. There are two species, one of the herbaceous flowery animals, or shrubby perennial, growing erect from two or three to eight or ten feet high. They are easily propagated by seed in the open ground in the spring, and thrive best in a warm season where the plants are designed to remain.

LAUDANUM. See Pharmacy.

LAUGERIA, a genus of the monogynia order, in the petunia class of plants, and in the natural method ranking among those of which the order is double. The corolla is quinquefid; the fruit is a plum with a quinquelocular kernel. There are two species, shrubs of the West Indies.

LAUNCH, in the sea-language, signifies to put out: as, launch the ship, that is, put it out of the dock; and forward, speaking of things that are stowed in the hold, is, put them more forward. Launch, ho! is a term used when a yard is hoisted high enough, and signifies hoist no more.

LAUNDER, among miners, a place where they wash their supplies. It is sometimes used by the miners as a washing place.

LAUREATION, in the universities of Scotland, signifies the act of taking the degree of master of arts, which the students are permitted to do after four years study.

LAVRUS, the bay-tree, a genus of the monogynia order, in the petunia class of plants, and in the natural method ranking under the 12th order, holarcania. There is no calyx; the corolla is calycine, or serving in place of the calyx, and sepalata; the stamens are with three glandulae, each terminated by two bristles surrounding the germin. The interior florets furnished with glandulae at the base; the fruit a monogynous plum. There are: 32 species, of which the most 20 are successively grown bay-tree, a native of Italy, and has an upright trunk branching on every side from the bottom upward, with spear-shaped, nervous, stiff, evergreen leaves, three inches long, and six inches broad, large, glossy, quinquelocular, directed flowers, succeeded by red berries in autumn and winter. Of these species there are varieties, with broad, narrow, striped, or waved leaves. 2. The arbutis, or deciduous bay, grows naturally in North America. It rises with an upright stem, covered with a purplish bark, having oblong, oval, acuminate, veined, deciduous leaves, two or three inches long, and half as broad, growing opposite, with the lower leaves succeeded by red berries. 3. The benzoin, or benjamin tree, is also a native of North America; grows 15 or 20 feet high, divided into a very branchy head, with oval, acute, deciduous leaves, two and a half inches broad, and small yellowish flowers, not succeeded by berries in this country. This, it is to be remarked, is not the tree which bears the gum benzoin, that being a species of hexas. 4. The sassafras is a native of the same country. It has a shrub-like straight stem, with both oval and three-lobed, shining, deciduous leaves, of different sizes, from three to six inches long, and nearly as broad, with small yellowish flowers succeeded by blackish berries, but not in this country. 5. The indica, or Indian box-tree, rises with an upright straight trunk, branching regularly 20 or 30 feet high, adorned with very large, spear-shaped, plane, nervously, evergreen leaves, small white-green flowers, succeeded by large oval black berries, which do not ripen in this country. 6. The barbonia, or Carolina red-box-tree, rises with an upright straight stem, branching 15 or 20 feet high, with large, spear-shaped, evergreen leaves, transversely veined; and long bunches of flowers on red footstalks, succeeded by large blue berries sitting in red cups. 7. The canis, or canis-tree, grows naturally in the woods of the western parts of Japan, and in the adjacent islands. See Plate Nat. Hist. fig. 244. The root smells stronger of camphor than any of the other parts, and yields it in greater plenty. The bark of the stalk is outwardly somewhat rough; but in the inner surface smooth and mucous, and therefore easily separated from the wood, which is dry, and of a white colour. The flowers are produced in small bunches in the top of the stalk; the fruit, or the berries, succeed by the armpits of the leaves; but not till the tree has attained considerable age and size. The flower-stalks are slender, branched at the top, and divided into very short pedicels, supporting a single blossom. These flowers are white, and consist of six petals, which are succeeded by a purple and shining berry of the size of a pea, and in figure somewhat top-shaped. It is composed of a white substance, till pulpily torn out, with the taste of cloves and camphor; and of a nucleus or kernel of the size of a pepper, which is covered with a black, shining, oily coricile, of an insipid taste. 8. The cinnamomum, or cinnamon-tree, is a native of Ceylon. It has a large root, and divides into several branches, covered with a bark, which, on the outer side is of a greyish brown, and on the inside has a reddish cast. The wood of the root is hard, white, and has no smell. The body of the tree, which grows to the height of 20 or 30 feet, is covered, as well as its numerous branches, with a bark which at first is green and afterwards red. The leaf is larger and more move tree; and it is threeseweed, the nerves vanishing towards the top. When first unfolded, it is of a flanne-colour; but after it has been for some time exposed to the air, and grows dry, it changes to a deep green on the upper surface, and to a lighter on the lower. The flowers are small and white, and grow in large bunches at the extremity of the branches; they have an agreeable smell, something like that of the bay, and of the myrt. The fruit is shaped like an acorn, but is not so large. 9. The cassia, or base cinnamon, has lancedolated leaves, triple-nerved. 10. The person, avocado-pears, or alligator pear, rises to a considerable height, with a straight trunk, of which the bark and wood are of a greyish colour. The leaves are long, oval, pointed, of a substance like leather, and of a beautiful green colour. The flowers are produced in clusters at the extremities of the branches, and consist each of six petals disposed in the form of a star, and of a dirty-white or yellow colour, with an agreeable odour, which diffuses itself to a considerable distance. It is a native of the West Indies. The petals be-
LAW

Laws of England are divided into
civil, or private, and
common law, or lex
sine scripta.

The law non scripta is not so
called from its being conveyed from
former ages by word of mouth, but because the
original authority of the rules is not found in
writing, and they receive their force by long
usage, and by their universal reception
throughout the kingdom; and it is curious
to observe, that those rules maxims of our
ancestors, of which no person knows clearly
the origin, exceed in clearness, brevity, and
authority, all that the united wisdom of the
most enlightened men have produced in later
times.

The common law is divided into
1st. General custom, which is the
universal rule of the whole kingdom, and is the
law by which proceedings and determinations in
the courts of justice are ordinarily directed.
This for the most part settles the course of
inheritance, the manner and form of acquiring
and transferring property, the solemnities and
obligations of contracts, the rules of
exchanging, wills, deeds, and acts of parliament;
the redress of civil injuries, the different kinds
of remedies with the punishments allotted to
each; the institution of four superior courts
of record; and many other particulars which
differ themselves as extensively as the
distribution of common justice requires, all of
which are not connected by any particular
statutes (though they are acknowledged by all)
but depend entirely upon the common law.

2ndly. Particular customs which concern
the inhabitants of some particular district.

3rdly. The third branch are those laws
which are adopted by certain courts and juris-
dictions, as the civil and canon laws.

The civil law is understood to signify
the civil law of the Roman empire. The
canon law is a body of Roman ecclesiastical
law relating to matters over which the church
exercises a jurisdiction. The civil law is used
in four courts under certain restrictions, viz.
the archbishop's and bishops' courts, usually
styled curia christiana; the courts mar-
tial, the courts of admiralty, and the courts
of the two universities.

The second division of the laws of England
are the statutes made by the king, lords,
and commons, assembled in parliament. The
oldest statute extant is the celebrated Magna
Charta, 9 Hen. 3: though, doubtless, the records
of many antecedents to that have been lost,
and the maxims received as common
law.

Statutes are general or special, public or
private: general or public acts, are those
which concern the whole nation; and these
judges are obliged to take notice, though they
should not be formally pleaded by the
party who claims an advantage under them.
Special or private acts are such as operate on
private persons and concerns, which must be
formally set forth by the party, or the judges
are not obliged to notice them.

Statutes are either declaratory of the
common law, where it is become disreputable, or
fallen into disuse; or remedial, when made
to supply the defects, or abridge the superflui-
ties of the common law. These latter are
subdivided into enabling and restraining
statutes, by enlarging the common law where it
was too circumscribed, and restraining it
where it was too luxuriant.

There are also theounds of the laws
of England, a court of equity to moderate and
explain them. (See Equity.) The courts of
equity are, however, only had recourse to
in matters of property; for our constitution
will not permit the courts of common law to
 treat in cases any
judge should have the power of construing
the law otherwise than according to the
letter. This caution, while it protects the
public liberty, can never oppress the individual.
A man cannot suffer more punishment than
the law directs, but he may suffer less. The
laws cannot be strained to inflict a penalty
beyond what the letter warrants, but in cases
where the letter induces any apparent hard-
ship, the crown has power to pardon.

In treating of the laws, the best mode, and
which has been of the greatest use, is to
follow William Blackstone in his excellent Commentaries,
after the example of Wood in his Institutes, is to
divide them, 1st, into the rights of persons,
or the rights as to personal security, personal
liberty, and property. 2nd. The rights of
things, or the rights which a man may acquire in and to such external things as
are unconnected with his person.
3rd. Private wrongs, or such as are the
infringement of the private rights of individuals; and
4th. public wrongs, or such as are a violation
of the public rights, and affect the whole
community.

It is of course unnecessary, and perhaps a
work of this nature irrelevant, to recommend
the study of the law; it is sufficient to add
the words of the great judge Blackstone on
this subject. "It is incumbent (says he)
upon every man to be acquainted with the
laws, lest he incur the censure as well as the
inconvenience of living in society without
knowing the obligations it lays him under."

LAVENIA, a genus of the class and order
syngenesia polygamia aequalis. The calyx is
nearly regular; style bifid; fruit three
seeds; roots white, two species.

LAWSIONIA, Egyptian privet; a genus of
the monocotyledon order, in the octandria
class of plants, and in the natural method
ranking with those of which the order is
doubtful. The calyx is quadriparted; the petals
four; and the stigma four, in pairs; the capsule is quadri-
particular and polysemous. There are four
species, all natives of India. Some authors
take the mimosa to be the plant termed by the
Greeks henna or alcaena, the pulverised
leaves of which are much used by the
Eastern nations for dying their nails yellow;
but others, Dr. Hassequist in particular,
attribute that effect to the leaves of the other
species of Egyptian privet which bears prickly
branches. It is probable that neither set
of writers are mistaken, and that the shrub in
question is a variety only of the thorny lav-
sonia, rendered mild by culture.

LAY-BROTHERS, among the Roman-
istians, those whom they call persons who
devote themselves, in some convent, to
the service of the religious. They wear a
different habit from that of the religious, but
never enter into the choir, nor are present at
the chapters; nor do they make any other
vows, except of constancy and obedience. In
numeraries there are also lay-sisters.

LAY-MAN, among painters, a small statue
either of wax or wood, whose joints are so
formed, that it may be put into any attitude
or posture. Its principal use is for adjusting
the drapery in cliuring.

LAYERS, in gardening, are tender shoots or
twigs of trees, laid or buried in the ground,
till, having struck root, they are separated
from the parent tree, and become distinct
plants. The propagating trees by layers is
done in the following manner: the branches
of the trees are to be slit a little way, and laid
under the mould for about half a foot; the
ground should be first made very light, and
after they are laid they should be gently wa-
tered. If they will not remain easily in the
position they are put in, they must be pegged
down with wooden hooks: the best season for
doing this is, for evergreens, toward the end
of August; and for other trees in the begin-
ning of June. If a William Blackstone have
a taken root, they are to be cut off from the main
plant the succeeding winter, and planted out.

If the branch is too high from the ground, a
spout of earth is to be raised to a proper height
on the root. 2nd. The branch may be either tied
round with a wire, or cut round for an inch or two at the place, and it
is a good method to pierce several holes through it with an awl above the part tied
with the wire.

LAZAR-HOUSE, or LAZARETTO, a
public building, in the nature of an hospital,
to receive the poor and those afflicted with
contagious distempers: in some places lazare-
rettos are appointed for the performance of
quarantine; in which case, those are obliged
to be confined in them who are suspected
to have come from places infected with the
plague. This is usually a large building, at
some distance from a city, whose apartments
are detached from each other, where ves-
ticles are given, and the crew shut up for
about 40 days, more or less, according to the
time and place of their departure. The laza-
retto of Milan is esteemed one of the finest
hospitals in Italy.

LAZULITE. This stone, which is found
chiefly in the northern parts of Asia, was long
known to mineralogists by the name of lapis
lazuli.

Lazulite is always amorphous. Its texture
is earthy. Its fracture uneven. Lustre 0.43.
Opaque, or nearly so. Hardness 8 to 9. Spec-
tral gravity 2.74. Colour blue; often
dotted white from specks of quartz, and
dot from particles of pyrites.

It retains its colour at 100° Wedgewood;
but it is heated higher it becomes more and more a yellowish-brown mass. With acids it effec-
tes a little, and if previously calcined,
turns with them a jelly.

Marggraf published an analysis of lazulite
in the Berlin Memoirs for 1758. His ana-
lysis was confirmed by Kliprauch, who found a specimen of it to contain

LEAD.

The deutoxide of lead may be formed by dissolving the metal in nitric acid, and pouring pon expanding it with a yellow-coloured powder is obtained, which is the deutoxide of lead. This oxide is composed of 91 parts of lead, and 9 of oxygen. When lead is kept melted in an open vessel, its surface is soon covered with a grey-coloured powder. When this powder is removed, another succeeds it; and by continuing the heat, the whole of the lead may soon be converted into this substance. If these powders are heated and agitated for a short time in an open vessel, they assume the form of a greenish-grey powder. Mr. Proust has shown that this powder is a mixture of deutoxide, and a portion of lead in the metallic state. It retains its green colour to the blue and yellow powders which are mixed in it. If we continue to expose this powder to heat for some time longer in an open vessel, it absorbs more oxygen, assumes a yellow colour, and is then known in commerce by the name of massicot. The reason of this change is obvious. The metallic portion of the powder gradually absorbs oxygen, and the whole of course is converted into deutoxide.

When these powders are exposed to the vapour of warm vinegar, they are gradually corroded, and converted into a heavy white powder, used as a paint, and called white lead. This powder used formerly to be considered as a peculiar oxide of lead; but it is now known that it is a compound of the deutoxide and carbonate of lead.

3. If massicot ground to a fine powder is put into a furnace, and constantly stirred while the flame of the burning coals plays against its surface, it is in about 48 hours converted into a beautiful red powder, known by the name of minium, or red lead. This powder, which is likewise used as a paint, and for various other purposes, is the tritoxide or red oxide of lead.

4. If nitric acid, of the specific gravity 1.200, is poured upon the red-coloured oxide of lead, 183 parts of the oxide are dissolved; but 13 parts remain in the state of a black, or red oxide, which is the peroxide, or brown oxide of lead, first discovered by Scheele. The best method of preparing it is the following, which was pointed out by Proust, and afterwards still farther improved by himself. Four pounds of red oxide of lead into a vessel partly filled with water, and make oxymuriatic acid gas pass into it. The oxide becomes deeper and deeper coloured, and is at last dissolved. The solution, and the brown oxide of lead precipitates. By this process 68 parts of brown oxide may be obtained for every 100 of red oxide employed. This oxide is composed of about 79 parts of lead and 21 of oxygen. It is of a brilliant dull brown colour. When heated it emits oxygen gas, becomes yellow, and melts into a kind of glass. When rubbed along with sulphur in a mortar, it sets the sulphur on fire, and causes it to burn with a brilliant flame. When heated on burning coals the lead is reduced. All the oxides of lead are very easily converted into glass; and in that state they oxidize and combine with almost all the other metals except gold and silver. This property renders lead exceedingly useful in separating gold and silver from the baser metals with which they happen to be contaminated. The gold or silver to be purified is melted along with lead, and kept for some time in a cup, made of burnt boxes, or the ashes of wood. The lead is gradually vitrified, and sinks into the cup, carrying along with it all the metals which were mixed with the silver and gold, and leaving the metals on the cup in a state of purity. This process is called cupellation. The lead employed is afterwards extracted from the cup, and is known in commerce by the name of lighthouse. It is a half-fusible yellowish-white powder, of a dull colour, and composed of scales. It is merely an oxide of lead more or less contaminated with the oxides of other metals. But the best lighthouse is made by oxidizing lead directly, and then increasing the heat till the oxide is fused. The more violent the fusing heat, the whiter is the lighthouse.

Lead has not yet been combined with carbon, nor hydrogen; but it combines readily with sulphur and phosphorus.

1. Sulphur of lead may be formed either by straining its two component parts, and melting them in a crucible, or by dropping sulphur on intervals on melted lead. The sulphuret of lead is brittle, brilliant, of a deep blue-grey colour, and almost black on the edges of the lead. These two substances are often found naturally combined; the compound is then called galena, and is usually crystallized in cubes. Sulphuret of lead is composed, according to the experiments of Vonzel, of 86.8 parts of lead and 13.2 of sulphur.

2. Phosphuret of lead may be formed by mixing together equal parts of filings of lead and phosphoric glass, and then fusing them in a crucible. It may be cut with a knife, but separates into plates whenhammered. It is of a silver-white colour with a shade of blue, but it soon tarnishes when exposed to the air. This phosphuret may also be formed by dropping phosphorus into melted lead.

It is composed of about 12 parts of phosphorus, and 88 of lead.

Lead does not combine with azotic gas. Muriatic acid gradually corrodes it, and converts it into a white-coloured oxide.

Lead is capable of combining with most of the metals.

1. Lead may be easily alloyed with gold by fusion. The colour of the gold is injured, and soon changes on exposure to the air. Many experiments have been made with this alloy, in order to possible to purify platinum from other metals by cupellation, as is done successfully with silver and gold, but scarcely any of the experiments have succeeded; because platinum requires a much more violent heat to keep it in fusion than can be easily given.

2. Platinum and lead unite in a strong heat: the alloy is brittle, of a purplish colour, and soon changes on exposure to the air. Many experiments have been made with this alloy, in order to possible to purify platinum from other metals by cupellation, as is done successfully with silver and gold, but scarcely any of the experiments have succeeded; because platinum requires a much more violent heat to keep it in fusion than can be easily given.

3. Silver is often alloyed with lead in order to purify it by cupellation. This alloy is very fusible, much softer than silver, but much less tenacity, elasticity, and toughnessness; its colour is nearly that of lead, and its specific gravity greater than the mean density of the metals alloyed.

4. Mercury assimilates readily with lead in any proportion, either by triturating it with lead filings, or by pouring it upon melted lead.
LEAD. See Botany.
LEA-GOLD. See Aurum, Gold, Gilding, etc.
LEAF. See Architecture.

LEAF, in clocks and watches, an application given to the matches of their pinions. See Clockwork.

LEAGUE, a measure of length, containing more or less geometrical pieces; according to the different usages and customs of countries. A league at sea, where it is chiefly used by us, being a land-measure mostly peculiar to the French and Germans, contains three English leagues or four English miles. The French league sometimes contains the same measure, and in some parts of France it consists of three thousand five hundred paces; the mean or common league consists of two thousand and four hundred paces, and the little league of two thousand. The Spanish leagues are larger than the French, seventeen Spanish leagues making a degree, or twenty French leagues, or sixty English leagues, 200 English statute miles. The Dutch and German leagues contain each four geographical miles. The Persian leagues are pretty near the same extent with the Spanish; that is, they are equal to 17 English, and it is said to be near to what Herodotus calls the length of the Persian parang, which contained thirty stadia, eight of which, according to Strabo, make a mile.

LEAK, a small leak, a hole in the ship through which the water comes in. To spring a leak is said of a ship that begins to leak; to stop a leak, is to fill it with a plug wrapt in oakum and well tarred; or putting in a tarpaulin cloth, to keep the water out; or nailing a piece of sheet-lead upon the place.

LEAKAGE, the state of a vessel that leaks, or lets water, or other liquid, ooze in or out. See the preceding article. Leakage, in commerce, is an allowance of 12 per cent. in the customs, allowed to importers of wines for the waste and damage it is supposed to have received in the passage; an allowance of barrels in twos, which are also made to the brewers of ale and beer, by the excise-office.

LEAK, in music. This word is properly applicable to any disjunct degree, but is generally used to signify a distance consisting of several intermediate intervals.

LEAK-YEAR. See BISEXTILE.

LEASE, a conveyance of lands, generally in consideration of rent or other annual recompense made for life, years, or at will, but always for a shorter term than the lessor has in the premises, otherwise it partakes more of the nature of an assignment.

By the common law, all persons seized of an estate might grant leases for any period less than their interest lasted; but statutes have been since made, some to enlarge and some to restrict it. They are divided into enabling and restricting statutes; by the enabling stat. 32 Henry VIII. c. 28, a tenant in tail may make leases to endure for twenty-one years or three lives to bind his issue in tail, but not those in remainder or reversion. Husband seized in right of their wives may make leases for the same period, provided the wife join in it. All persons seized of an estate of fee-simple in right of their churches, except parsons or vicars, may bind their successors under certain restrictions. 1. The lease must be by indenture; 2. It must be for a term of years of making; 3. All old leases must be surrendered or be within a year of expiring; 4. It must be for three lives or twenty-one years, not both; 5. It may be for a shorter term, but must not exceed seven years; 6. It must be of lands and tenements, or lands only let for twenty years part; 7. The most usual rent for that time must be reserved; 8. Such leases cannot be made without imprisonment of the land.

From the disabling statutes, we find that all colleges, cathedrals, and other ecclesiastical or deanonary corporations, and all parsons and vicars, are restrained from making leases unless under the following regulations. They need 3 lives or 21 years; the accustomed rent must at least be reserved thereon: 3. Houses in corporations or market-towns may be let for 40 years, provided they are not the mansions of the lessors; but not more than 10 acres of ground belonging to them; and provided the lessee agrees to keep them in repair, and they may be aliened in fee-simple for lands of equal value in recompense: 4. If there is an old lease which has been more than 3 years to run, no new lease shall be made: 5. No lease shall be made without imprisonment of waste: 6. All bonds and covenants tending to frustrate the provisions of the statutes of 13 and 18 Eliz. shall be void.

Two observations seem to present themselves concerning these statutes: 1. That they do not enable any persons to make such leases as they are by common law restrained from making; therefore, a parson or vicar, though it is restrained from making longer leases than for 21 years 3 lives, even with the consent of the patron or ordinary, yet is not enabled to make any lease at all, to bind his successor without such consent. 2. If leases granted to these acts are void, yet they are good against the lessor during his life, if he is a sole corporation; and it is an aggregate corporation, as long as the head lives: for the act was intended for the benefit of the successor alone, and it is a maxim of law that no man shall take advantage of his own wrong. With regard to college leases, one-third of the old rent must be reserved in wheat or malt, reserving a quarter of wheat for every 6l. and a quarter of malt for every 5s. or the leases must pay for the same, at the price of the market nearest the respective colleges on the market-day before the rent is due.

There are further restraining statutes which direct that if any beneficed clergyman is absent from his benefice above 80 days in the year, all leases and agreements made by him of the profits of his cure shall be void, except in the case of licensed pluralists; who are allowed to damnum this cure, if he is not absent above 40 days in the year. See 13 Eliz. c. 40. 14 Eliz. c. 11. 18 Eliz. c. 11. and 43 Eliz. c. 9.

All leases except such as do not exceed
3 years from the making, whereupon the reserved rent must be at least two-thirds of the improved value of the estate immediately after it is improved, and it is no particular term of words is necessary to constitute a good lease. They must be made to natural-born subjects of this realm, or issued by a naturalized, or to descendents, for all leases made to aliens shall be void; and there is even a statute in force, 32 Hen. VIII. c. 16, which imposes a penalty of 5l. on the lessor and lessee. It has however been held that an alien merchant may take a lease for his own residence, but it shall not go to his executors; the reasons for these laws are evidently to prevent foreigners getting too firm a footing in the kingdom.

**LEASE and LEASE is a conveyance which since the stat. 27 Hen. VIII. c. 10, commonly called the statute of uses, has taken place of the deed of feu-duty, as it supplies the need of livery and seisin. It is made thus: A lease or bargain and sale for one year, from the tenant to the lessee, is first prepared, whereby the lessee becomes actually possessed of the lands, then by the above-mentioned statute the lessee is enabled to take a grant of the land intended to be conveyed to him and his heirs for ever; accordingly a release is made, reciting the lease and declaring the uses. In the lease, a pepper-corn is a good consideration to make the lessee capable of receiving a release. This mode of conveyance is become so usual, that it merits particular attention. See this matter very ably discussed by the annotator of the latter part of Coke's Commentaries, p. 271.**

### LEASES, value of.

**The purchaser of a lease may be considered as the purchaser of an annuity equal to the rack-rent of the estate; and the same principles, from which are deduced the present value of annuities to continue during any given term, will apply to the value of leases. The sum paid down for the grant of a lease is so much money paid in advance for the annual rents, as they may be due. It may be considered as a sum which puts out to interest, will enable the lessee to repay himself the rack-rent of the estate, or the yearly value of his interest therein, during the given term; therefore no money should be demanded by the lessor, for the grant of the lease, than will enable him to do this at a given rate of interest. In order to find what this sum should be it would be necessary to ascertain separately the present value of each annual rent, or the sum which, put out at interest at the given rate, will enable the landlord to repay himself the several yearly rents as they become due. Thus, if a person has 100l. due to him a twelvemonth hence, and he wishes to have the value of the same advanced immediately, the sum that ought to be given as an equivalent therefor, allowing 5 per cent. interest, is 95l. 4s. 9d.; for this is the sum which, put out at interest at the rate of 5 per cent., will, at the end of the year, amount to 100l. So also, if a person has 100l. due to him at the end of two years, and he wishes to have the value advanced immediately, the sum that ought to be given as an equivalent therefor, is 90l. 14s. 3d. For this is the sum which put out at the same rate of interest, will, at the end of two years amount to 100l. In the same manner, if a**

</table>

In order to find the value of a lease, it is first necessary to ascertain the true rack-rent of the estate, or the annual value that it may be justly estimated to be worth; otherwise it will be impossible to determine, with any degree of accuracy, the real sum which ought to be given for the purchase of the same. On this point difficulties will sometimes arise; for the value of an estate depending very often on some real or supposed advantages, or on some local or personal recommendations, will, in many instances, occasion a difference of opinion; and in most cases, be a matter of some uncertainty. However, when all these circumstances have been taken into consideration, some annual rent equivalent thereto must be assumed, and when this is settled the value of the lease will be easily found; thus, if an estate is worth 100l. per annum rent, the value thereof for sixty-nine years, allowing the purchaser 6 per cent interest for his money, is 16,3670 (the number in the table) multiplied by...
lee, corolla, if glume, is therefore the by required, 5 given payable calculated that is chase chaser rent the the not set duct seven years,。“ 

five, of the given value, that be entered of estate of the number of years, or the unexpired value of the unexpired term of six years, or the number of years purchase in the table ought to be multiplied by the difference only between such annual expense and the whole estimated rent of the estate; thin if a person possesses an unexpired term of sixty years in a lease, for which he pays 100/. per annum rent, but which is now worth 150/. per annum, the gross sum which he ought to receive for the grant of such lease, will be equal to $100/ x (150 - 100)/100 = 50/ per annum, for the given term; or 16,1614 (the number in the table corresponding with 60 years, at 6 per cent.) multiplied by 50, which gives 800.L. is 4d.

In order to find the annual rent corresponding to any given sum paid for a lease, divide the sum paid by the number of years purchase that are found against the given term in the table, and the quotient will be the annual rent required. Example: A person pays £1000 for the lease of an estate for 16 years, what annual rent is equivalent thereto in order to allow the purchaser 7 per cent. interest for his money? In the table against 16 years, and under 7 per cent. column, the number of years purchase to be 9,4466; therefore 1000 divided by 9,4466 gives 105/. 17s. for the annual rent required.

The values in the table are calculated on the supposition that the payments of the sever al rents of the estate are made yearly; hence, if the payments are made half-yearly, or quarterly, and the purchaser can put his money at the same rate, so as to receive his interest half-yearly or quarterly, which may commonly be done; the values will, in such cases, be somewhat more than those given in the table. The difference, however, is not very great, but if the exact value is required, it may in many cases be obtained by attending to the following remarks, viz. in the case of the rent of which is payable half-yearly, is equal to half the value of the same lease payable yearly, calculated at half the given rate of interest, and to continue double the number of years; and that the value of a lease the number of years which is payable quarterly, is equal to one quarter the value of the same lease payable yearly, calculated at a quarter of the given rate of interest, and to continue four times the number of years.

It frequently happens that a long lease is not to be entered on or enjoyed till after the expiration of a short lease, or till the end of a given number of years; in such cases, deduct the value of the short lease, or the value set against the given number of years in the table, from the value of the longer lease, and the difference will give the true present value of the longer lease. Example: What sum ought to be given for the remainder of the lease of an estate for 56 years, after the next seven years, allowing the purchaser 6 per cent. interest for his money, the clear rent being reckoned at 70L. per annum? In the table against 56 years, and under 6 per cent. we find 10.406, and in the same column against 49 years, we find 10.529; the latter value subtracted from the former leaves 10.403, which multiplied by 70 gives 731.255 or 731.5/. 1d. for the sum required.

Leases are frequently granted during a life, or for a specified term of years subject to the payment of a fine. The following are given in a very useful collection of tables for the purchasing and renewing of leases by F. Bally, and may in most cases be found from the tables inserted under the article LIFE ANNUITIES.

LEATHER. See Cuts, and Tanning.
LEAVEN. See Fermentation.
LECHEA, a genus of the triandria tri-gynia class and order. The calyx is three-parted; petals, three-linear; capsules, three-seeded, three-valved, seeds solitary. There are three species, herbaceous plants of America and China.

LEYCITHIS, a genus of the poylanthra monogynia class and order. The calyx is six-parted; petals, six-petalled; nectarium, bifatulate, staminate: pericarp, circinnate, six; seed many-seeded. There are six species, trees or shrubs of Guiana.

LEDGER, the principal book wherein merchants enter their accounts. See Book-keeping.

LEDGES, in a ship, are small pieces of timber lying athwart from the roof-trees to the roof-trees: they serve to bear up the gratings or nettings of the half-deck. See Ship-building.

LEEDUM, marsh eustus, or wild rosemary; a genus of the monogynia order, in the de-candria class of plants; and in the natural method ranking under the 18th order, bi-corns. The calyx is quinquepartite; the corolla plain and quinquepartite; the capsule quinquilocular, and opening at the base. There are three species: The palustre with very narrow leaves, grows naturally upon banks and moors in many parts of Yorkshire, the flower is produced in small clusters at the end of the branches, and are shaped like those of the strawberry-tree, but spread open wider at top: these are of a reddish colour, and in the natural places of these flowers are succeeded by seeds-seeds filled with small seeds which ripen in autumn.

LEE, in the sea-language, a word of various significations, though it is generally understood to mean the part opposite to the wind. Thus lee-shore, is that shore against which the wind blows. Lee-latch, or have a care of the lee-latch, is, take care that the ship don't go to the leeward, or too near the shore; a command, put it to the leeward side of the ship; to be by the lee, or to come up to the lee, is to bring the ship so, that all her sails may lie flat against her masts and shrouds, and that the wind may come right upon her breadlips.

LEEMING, is a rope riveted into the cringles of the forecastle, to hold in the bottom of the sail, that the booms may be laced on, or the sail taken in.

LEES-WAY, is the angle that the rhumb-line upon which the ship endeavors to sail, makes with a line drawn from the place where the wind is, to the shore. See Navigation.

LEEEA, a genus of the class and order peptonandra monogynia. The calyx is one-petalled; neat; on the side of the corolla, upright, five-celled; berry, five-seeded. There are three species, grasses of America.

LEECH, See Hirudo.
LEEK, See Allium.
LEERIA, a genus of the class and order triandria digynia. Calyx none; gume, three-valved, closed. There are three species, grasses of America.

LEFT, a little court held within a manor, and called the king's court, on account that its authority to punish offences originally belonged to the crown, where it is derived to inferior persons. See Court.

LEETCH-lights, small ropes made fast to the leech of the topsails, to which they belong, and reeved into a block at the yard close by the topsails. They serve to take in the leech of the sail when the topsails are to be taken in.

LEGACY, a bequest of a sum of money, or any personal effects of a testator: and these must be paid by his representative, after all the debts of the estate are discharged, as far as the assets will extend.

All the goods and chattels of the deceased, are by law vested in the representative, who are required to see whether there be left a sufficient fund to pay the debts of the testator, and if it should prove inadequate, the pecuniary legacies must proportionately abate: a specific legacy, however, is not to abate unless there be insufficient without it.

If the legatee die before the testator, such will in general be termed a lapsed legacy, and fall into the general fund; where however, from the general import of the will, it can be collected that the testator intended such a vested legacy, it will in such case go to the representative of the deceased legatee.

If a bequest be made to a person, if or when he attains a certain age, the legacy will be lapsed, if he die before he attain that age: but if such legacy be made payable at that age, and the legatee die before that age, such legacy will be vested in his representative.

In the latter case, the testator devise interest to be paid in the mean time, it will nevertheless be a vested legacy.

Where a legacy is bequeathed over to another, in case the first legatee die under a certain age, or the like, the legacy will be payable immediately on the death of the first legatee; and though such legacy be not bequeathed over, yet if it carry interest, the representative will become immediately entitled to it.

In case of a vested legacy due immediately, and charged on land, or money in the funds which yields an immediate profit, interest shall be payable from the death of the testator; but if be charged on the personal estate only of the testator, which cannot be collected in, it will carry interest only from the end of the year after the death of the testator.

If a request be for necessities, and of small amount, the executor will be justified in advancing a part of the principal; but this should be done under very particular circumstances, as the executor may be compelled to pay the full legacy on the infant's attainder of age, but deducting the sum previously advanced.
When all the debts and particular legacies are discharged, the residue or surplus must be paid to the residuary legatee, if any be so appointed in the will; but if there be none appointed or intended, it will go to the executor or next of kin.

When this residue does not go to the executor, it is to be distributed among the intestate's next of kin, according to the statute of distributions; except the same is otherwise disposed of by particular customs, as those of London, York, &c. See Executor.

LEGATE, a cardinal or bishop, whom the pope sends as his ambassador to sovereign princes.

There are three kinds of legate, viz., legates a latere, legates de latere, and legates by office, or legati nati; of these the most considerable are the legates a latere, the next are the legates de latere.

Legates by office are those who have not any particular legation given them, but who, by virtue of their dignity and rank in the church, become legates; such are the archbishops of Rheims and Arles; but the legation of a cardinal is much inferior to that of the legates a latere.

LEGATUS, in Roman antiquity, a military officer who commanded as deputy of the chief general.

LEGEND, in music, one added to the staff of five lines, when the ascending or descending notes run very high or low.

LEGION, in Roman antiquity, a body of foot which consisted of ten cohorts.

The exact number contained in a legion, was fixed by Romulus at three thousand; though Plutarch assures us, that after the reception of the Sabines into Rome, he increased it to six thousand. The common number afterwards, in the first times of the free state, was four thousand; but in the war with Hannibal, it arose to five thousand, and after this it is probable that it sunk again to four thousand, or four thousand two hundred, which was the number in the time of Titus.

LEGNOTIS, a genus of the class and order polyandria monadynia. The calyx is five-dent; pet. 5; caps. 3-celled. There are two species, from Guiana.

LEMA, in mathematics, a proposition which serves previously to prepare the way for the more easy apprehension of the demonstration of some theorem, or construction of some problem.

LEMNA, a genus of the monoeica diandria class and order. The male cal. is one-leaved; cor. none; style one; ovary one-celled. There are six species, known by the name of duckweed, or duck-meat.

LEMINISEA, a genus of the class and order polyandria monadynia. The cal. is 5-toothed; cor. 6-petalled, recurved; nect. capp. shaped, girding; the germ. per. 5-celled, seeds solitary. There is 1 species, a tree of Guiana.

LEMON. See Citrus.

LEMON; salt of. See OXALAT of potass.

LEMYER, M. a genus of quadrupeds of the order primates; the generic character is, front-teeth in the upper jaw, four; the intermediate one remote: in the lower jaw, six; longer, stretched forwards, compressed, parallel, approximated. Canine teeth solitary, approximated; grinders several, subobtund; the foremost somewhat longer and sharper.

The genus lemur or macecon consists of animals approaching to monkeys in the form of their feet, which, in most species, are furnished with nails or claws in their manus, and void of that mischievous and pestulant disposition which so much distinguishes the monkey tribe from other quadrupeds.

In this, as in the former genus, we meet with some species without a tail, while others have that part extremely long. Of the tail-less species the most remarkable is the 1. Lemur tardigrados, slow lemur. It is about the size of a small cat, measuring sixteen inches in length; its colour is an elegant pale-brown or mouse-colour; the face flatish; the nose inclining to a sharpened form; the eyes yellow-brown, large, and extremely protrubent, so as to appear in the living animal like perfect hemispheres. They are surrounded by a circle of dark brown, which also runs down the back of the animal. This species is very slow in its motion, and is a very rare sight; it is greatly esteemed for its flesh by some naturalists among the sloths; though in no other respect resembling them. It is a nocturnal animal, and sleeps, or at least lies motionless, during the greater part of the day; its voice is shrill and plaintive.

2. Lemur indri. This is a very large species; it is entirely of a black colour, except on the face, which is greyish; greyish nails in the hands and feet. The lacteal part of the abdomen, and the rump is white. The face is of a lengthened or dog-like form; the ears shortish and slightly tufted; the hair or fur is silky and thick, and in some parts of a curly or cripped appearance; its the largest animal of this genus, and is said by Mons. Sonnerat, its first describer, to be three feet and a half high; it is said to be a gentle and docile animal, and to be trained, when taken young, for chase, in the manner of a dog. It was by the name of the carrying off of an infant. It is a native of Madagascar, where it is known by the name of Indri, which is said to signify the man of the wood. The legs of this species are flat, but pointed at the ends; and covered with short hairs.

3. Lemur macaco, rufous lemur. This is the species described by the count de Buffon, under the name of the varius, its colours often consisting of a patched distribution of black and white; though its real or natural colour is supposed to be entirely black. In size it exceeds the mongs, or brown lemur. It is said to be a fierce and almost untameable animal; it inhabits the woods of Madagascar and some of the low islands; and is said to exert a voice so loud and powerful as to strike astonishment into those who hear it, resembling, in this respect, the howling monkey of S. Bolzebach, which fills the woods of Brazil and Guiana with its dreadful cries. When in a state of captivity, however, it seems to become as gentle as some others of this genus.

The astonishing strength of voice in this animal, amounts, according to the count de Buffon, on the peculiar structure of the larynx, which widens, immediately after its diversification, into a large cavity before entering the lungs.

4. Lemur tarsier. This animal is distin-
according to Tycho, thirty-seven; and in the Prutenic catalogues, there are not less than ninety-four. The star called the horned-beetle, coriicons, regius, and tardius, is a fixed star of the first magnitude.

To go on, in the left, a genus of the monotypia is, the Goniolidae class of plants; and in the natural method ranking under the 42nd order, coriicons. The coriicon is a sessile plant, its cylinder is conical, and deciduous. There are three species, natives of the southern parts of Europe, two of which are sometimes cultivated in this country. These are, 1. The chrysogonium with winged leaves; and 2. The leontopetalum with compound leaves. But those plants are natives of the Archipelago islands, and also grow in the corn-fields about Aleppo in Syria, where they flower soon after Christmas.

LEONOTODON, donclentia: a genus of the polygynia aronsilis, in the synge-nesan class of plants; and in the natural method ranking under the 49th order, composite. The leontopetalum is naked; the calyx imbricated, with the scales somewhat loose; the pappus feathery. There are four species, of which the only remarkable one is the taraxacum, or common dandelion, found on grasslands, and on the banks of ditches. Early in the spring, the leaves whilst yet white and hardly unfolded are an excellent ingredient in salads. The French eat the roots and tender leaves with bread and butter. Children that eat it in the evening experience its diuretic effects in the night, which is the reason for its vulgar appellation. When a swarm of locusts had destroyed the harvest in the island of Minorca, many of the inhabitants subsisted upon this plant. The expressed juice has been given to the quantity of four ounces three or four times a day; and Boerhava had a great opinion of the utility of this and other lacteous plants for the deaf. Gouty eat it; swine devour it greedily; sheep and cows are not fond of it, and horses refuse it. Small birds are fond of the seeds.

LEONURUS, lint's tail; a genus of the gynopogon class, in the dicotylidae class of plants; and in the natural method ranking under the 42nd order, vertalicile. The anther are powdery with shining points, or small elevated globular particles.

The species are: 1. The Africana, with scar-shaped leaves, a native of Ethiopia. The flowers are produced in whorls, each of the branches having two or three of these whorls towards their ends. They are of the lip-like shaped somewhat like those of the dead-nettle; but are much longer, and covered with short hairs. They are of a golden scarlet colour, so make a fine appearance.

2. The nepetafolia, with oval leaves, a native of the Cape of Good Hope. The flowers come out in whorls like those of the former sort, but are not so long nor so deep-coloured. They appear at the same season with the first, and continue as long in beauty. They are the same three species, but the above are the most remarkable.

Both sorts are propagated by cuttings, which should be exposed to the air long enough to harden the shoots, and planted in the beginning of July, after which they will take root very freely. They should be planted in a loamy border to an eastern aspect; and if the soil be not well withered with a hand glass to exclude the reflection of the sun, they will forward their putting forth roots.

As soon as they have taken root good, they should be taken up and planted each in a peat pot filled with loamy earth, and placed in the shade till they have taken new root. In October they must be removed into the greenhouse.

LEPIDAPUS, see LEPAS.

LEPIDONIDAE, Lepidoptera, lepididae: a genus of insects. They are, the amara, the shells, flattened at the base, and consisting of many unequal erect valves. The lepidus antlers, or duck-dermalica, lizes the shell compressed, five valued, smooth, seated on a bermica. They inhabit most seas, and is found fixed in clusters to the bottom of vessels, and old pieces of floating timber, generally whitish with a blue cast, the margins of the valves yellow; sometimes marked with black; peduncle long, coriaceous, black, and much wrinkled towards the shell, and growing paler and pellucid towards the base. See Plate Nat. Hist. fig. 243.

LEPIDIUM, dittander, or pepperwort: a genus of the siliculea class, in the coriicon class of plants; and in the natural method ranking under the 39th order, siliquose. The silicula is emarginated, corrated, and polyporomous, with the valves carinated contrary or broader than the partition. There are 23 species, of which the only remarkable one is the latifolium or common dittander. This is a native of many parts of England. The whole plant has a hot bitting taste like pepper; and the leaves have been often used by the country-people to give a relish to their viands instead of that spice, whence the plant has got the appellation of poor man's pepper. It is reckoned an astringent, and was formerly used instead of the horse-radish. See LEPIDOITA, see SERRATITRATIS.

LEPIDOPTERA, zoology, an order of insects with four wings, which are covered with imbrications squamae. In this to this that the mouth is commonly spiral.

Under this order are comprehended the phalana, sphinx, and other genera.

LEPSIMA, the name of a genus of insects of the order aptera. The generic character is, legs six, formed for running; mouth with two setaceous and two headed feelers; body imbricated with two minute scales; tail furnished with extended bristles.

The Limnanthus genus lepsima is far from extensive, those enumerated by Limnanthus himself in the twelfth edition of the Systema Naturae, amounting to no more than three species.

Of these the chief is the lepsima saccharina (See Plate Nat. Hist. fig. 243), frequently called in our own country, from its peculiar colour and tapering form, by the name of the wood-fish. This is an insect of great elegance. Its general length, exclusive of the caudal bristles, is about half an inch, and its colour a bright silver grey, resembling, in this colour being to a covering of extreme minute oval scales, which are semitransparent, very easily detached from the animal by a slight touch; the head and thorax together form a rounded outline, the remainder of the body gradually lessening to the tail, which terminate in three long bristles, of similar appearance with the antennae. The motions of this insect are slow and mild, and it is often observed among various domestic articles, particularly sugar. It also occurs not unfrequently among old books and papers, which it is supposed often to injure. It is said to be the American animal, and to have been imported into Europe among sugars, &c. Dr. Browne, in his History of Japan, represents it as "extremely destructive to books and all manner of woddle." See LEPSIUS.

Leptogonia pulvis Lin. is a dusky or brownish cast, and has a springing or leaping motion when disturbed. It is found about the sea-coast of many northern regions, under stones, &c.

LEPROSY. See Medicine.

LEPTURA, the name of a genus of insects of the order coleoptera: the generic character is, antenna scavece; wings sheathed, attempted towards the tip; thorax sub-cylindrical. The genus leptura, greatly allied to that of cerambyx, contains several species of considerable beauty; among which may be reckoned the leptura arcanu, of a brown, with the extremity marked by transverse, yellow, banded points pointing backwards; it is found in woods during the summer months, and generally measures about three quarters of an inch in length.

The leptura is of nearly uniform appearance, but the second band of the wing-sheaths is directed forwards; both the above insects are by some referred to the genus cerambyx.

Leptura aquatica is so named from its being particularly found in the neighborhood of waters, frequenting the plants which grow near the water's edge. It is about half an inch in length, and of a golden green-colour, sometimes varying into copper-colour, purple, or blue, and is distinguished by having a tooth or process on the thighs of the hind legs.

The larvae of the leptura in general are probably allied to those of the cerambyces, but they are at present unknown.

LEPSUS, hare, a genus of quadrupeds of the order glires. The generic character is, front-teeth two both above and below, the upper pair duplicate; two small inner ones behind. This genus, when considered with anatomical exactness, exhibits particularities of structure, deviating somewhat from that of the glire, and making an indistinct approach to the peccora or ruminants. It has even been supposed that the common hare actually ruminates; an opinion owing not only to peculiar motions of the mouth, which present an obscure appearance of ruminuation, but to the structure of the lepsus stomach, which is marked into two regions by a particular fold or ridge. Other singularities relative to internal formation may be met with in the works of comparative anatomists. The most remarkable species are, 1. Lepus timidus, common hare. This hare is an animal so familiarly known as to supersede the necessity of any very minute description. It is a native not only of every part of Europe, but of almost every part of Asia. It may perhaps be doubted whether it is an aboriginal native of any part of America.

The favourite residence of the hare is in rich and somewhat dry and flat grounds, and it is rarely discovered in very hilly or mount-
taneous situations. It feeds principally by night, and remains concealed during the day in its form, beneath some bush, or slight shelter.

The pox-willin of this animal is proverbial, and on account of the conformation of its legs, the hinder of which are longer than the fore, it is observed to run to most advantage on slightly ascending ground.

The hare is a very prolific animal, generally producing three or four young at a time, and breeding several times in a year, The young require the assistance of the parent but for a short time, and in about three weeks are able to provide for themselves; they do not remove to any great distance from each other, but continue in the same neighbourhood for a considerable time. The hare feeds on various vegetables, but is observed to prefer those of a milky and succulent quality. It also occasionally feeds on the bark of trees, as well as on the young shoots of various shrubs, &c.

The nature of the soil in which the hare resides and feeds, is observed to influence in a considerable degree the colour and constitution of the white fur in elevated situations are larger and darker than those which reside in the plains.

The hare is an animal proverbially timid, and flies, if disturbed when feeding by the slightest alarm; but when seated in its form, will allow itself to be approached so near as to be reached by a stick; seeming to be fascinated by fear, and instead of endeavouring to fly, continuing to squat immovable, with its eyes fixed on its enemy. It is necessary, however, in order to conduct this movement, to approach in a gradual and circling manner.

The hare, though so nearly allied to the rabbit as to make the general descriptive distinction not very easy, is yet of different habits and propensities, and never associates with the latter animal. If taken very young, the hare may be successfully tamed, and in that state shews a considerable degree of attachment to its benefactors, though it continues shy to strangers, and is easily terrified. Those who have been accustomed to Mr. White, in his History of Selbourne, relates an instance which happened in that village, of a young leveret sucked and nursed by a cat, which received it very early under her protection, and continued to guard it with maternal solicitude till it was grown to a considerable size.

A most singular variety of this animal is something rare, which is furnished with rough and slightly branched horns, bearing a considerable resemblance to those of a roe-buck. This particularity, as strange as it is uncommon, seems to imply a kind of indistinct approach in this animal to the order perocera.

The hare is a short-lived animal, and is supposed rarely to exceed the term of seven or eight years. It may be proper to add, that in very severe winters, and especially in those of the more northern regions, the hare becomes entirely white, in which state it is liable to be mistaken for the following species.

2. Lepus variabilis, varying hare. This species is an inhabitant of the loitest alpine tracts in the northern regions of the globe; occurring in Norway, Lapland, Russia, Siberia, and Kamtschatka; and in our own island on the Alps of Scotland. The same species is also found to extend to America, particularly to the mountains of the Western States. In its general appearance it bears an extreme resemblance to the common hare, but is of smaller size, and has shorter ears and more slender legs. Its colour in a summer is a tawny grey, in winter entirely white, except the tips of the ears, which are black; the soles of the feet are also black, but are very thickly clothed with a yellowish fur. This animal is observed to confine itself altogether to elevated situations, and never to descend into the plains, or to mix with the common hare. The change of colour commences in the month of September, and the grey or summer coat reappears in April; but in the very severe climate of Siberia it continues all the year round. It has been sometimes found entirely coal-black, a variety which is also known to take place occasionally in the common hare. The varying hare sometimes migrates in great quantities to the coast to obtain food. Troops of five or six hundred have been seen to quit in this manner the frozen hills of Siberia, and to descend into the plains and woody districts, from which they again return in spring to the mountains.

3. Lepus Americanus, American hare. This animal is not much superior in size to a rabbit, measuring about eighteen inches. Its colour is usually white, but the common hare, to which it seems much allied; but the fore legs are shorter, and the hind ones longer in proportion. The belly is white; the tail black above and white beneath; the ears tipped with grey, and the legs of a pale-ferruginous colour. It is said to inhabit all parts of North America; and in the more temperate regions retains its colour all the year round, in which, while it flourishes extremely long and slivery; the edges of the ears alone retaining their former colour. It is said to be extremely common at Hudson's Bay, where it is considered as a favourite food, being caught once or twice a year, producing from five to seven at a time. It is not of a migratory nature, but always continues to haunt the same places, taking occasional refuge under the roots of trees, or in the hollows near their roots.

4. Lepus cuniculus, rabbit. The rabbit bears a very strong general resemblance to the hare, but is considerably smaller, and its feet are furnished with sharper and longer claws in proportion; thus enabling it to burrow in the ground, and to form convenient retreats, in which it conceals by day, and like the hare, comes out chiefly by night and during the early part of the morning to feed. Its colour, in the wild state, is a dusky brown, paler or whiter on the under parts, and the tail is black above and white below. In a domestic state the animal varies into black, black-and-white, silver-grey, perfectly white, &c.

The rabbit is a native of most of the temperate and warmer parts of the old continent, but is not found in the northern regions, and is not originally a native of Britain, but was introduced by the Romans. The general residence is in dry, chalky, or gravelly soils, in which it can conveniently burrow. It is so prolific an animal that it has been known to breed seven times in a year, and to produce no less than eight young each time. It is therefore not surprising, that in some countries it makes itself scarce by its increased numbers; and has occasioned a good deal of calamity, and that various arts of extirpation have been practised against it.

5. Lepus viscacia. This species is said to have the general appearance of a rabbit, but has a long bushy and bristly tail, like that of a fox, which the animal also resembles in colour; the fur on all parts, except the tail, is soft, and is used by the Peruvians in the manufacture of hats; it was also used by the ancient Peruvians for the fabric of garments, worn only by persons of distinction. In its manners this animal resembles the rabbit, burrowing under ground, and forming a double mansion, in the upper part of which it deposits its provisions, and sleeps in the other. It appears chiefly by night, and is said to defend itself when attacked by striking with its tail.

6. Lepus alpinus, alpine hare. This is a very different species from the alpine hare described by Mr. Pennant in the British Zoology, which is no other than the varying hare. The alpine hare is a far smaller animal, scarcely exceeding a guinea-pig (cavia cobis) in size, and measuring only nine inches in length. Its colour is a bright ferruginous grey, paler beneath; the head is long, and the ears short, broad, and rounded. See Plate Nat. Hist. fig. 246. It appears to have been described by Dr. Polian, who informs us that it is a native of the Altai mountains, and extends to the Lake Baikal, and even to Kamtschatka, inhabiting rough woody tracts amidst rocks and cataracts, and forming burrows beneath the rocks, or inhabiting the natural fissures, and dwelling sometimes singly, and sometimes two or three together. In their manners they greatly resemble some of the marmots or hamsters; preening, during the autumn, a plentiful asser-tion of the finest herbs and grasses, which they collect in company, and after dryng with great care in the sun, dispose into heaps of very considerable size, for their winter supply, a thing which is much dis-eased, even through the deep snow, having the appearance of so many hay ricks in miniature, and being often several feet in height and breadth. The alpine hare varies in size according to the different regions in which it is found, being largest about the Altai mountains, and smaller about Lake Baikal, &c.

7. Lepus ogotona, ogotona hare. This animal, says Dr. Pallas, is called by the Mongo- lians by the name of ogotona, and is an inhabitant of rocky mountains, or sandy plains, burrowing under the soil, or concealing itself under heaps of stones, and forming a soft nest at no great depth from the surface. It wanders about chiefly by night, and sometimes appears by day, especially in clouds of weather. In autumn it collects heaps of various vegetables for its winter food, in the manner as the alpine hare has been described, disposing them into neat hemispherical heaps of about a foot in diameter. These heaps are prepared in the month of September, and are entirely consumed by the winter.
LET

LE

LEVARI FACIAS, is a writ directed to the sheriffs for levying a certain sum of money upon the lands, &c. of a person who has forfeited his recognizance.

LEUVITE. This stone is usually found in volcanic productions, and is very abundant in the neighbourhood of Vesuvius. It is always crystallized. The primitive form of its crystals is either a cube or a rhombohedral dodecahedron, and its integrant molecules are tetrahedrons; but the varieties hitherto observed are all polyhedrons. The most common has a spherical figure, and is bounded by 24 equal and similar trapezoids; sometimes the faces are 18, 15, 30, 45, and triangular, pentagonal, &c. The crystals vary from the size of a pin's head to that of an inch.

The texture of the leuviite is foliated; its fracture somewhat conchoidal; specific gravity from 2.455 to 2.492; colour white, or greyish white. Its powder causes syrup of violets to assume a green colour. Inflatable by the blow-pipe. Gives a white transparent glass with borax. It is composed, as Klepgroth has shown, of

- 54 silica
- 23 aluminia
- 22 potassa

99.

It was by analyzing this stone that Klēphrosh discovered the presence of potas in the mineral kingdom, which is not the least important of the numerous discoveries of that accurate and illustrious chemist.

Lencis is found sometimes in rocks which have never been exposed to volcanic fire, and Mr. Dolomieu has rendered it probable, from the substances in which it is found, that the leaves of volcanoes has not been formed by volcanic fire, but that it existed previously in the rocks upon which the volcanoes have acted, and that it was thrown out unaltered in fragments of these rocks.

LEUCOJUM, great snow-drop, a genus of the monogynia order, in the hexandria class of plants, and in the natural method order, spathophyllous. The corolla is campanulate, dissipate, the segments increased at the points, the stigma simple. The species are 1. The vernum, or spring leucumin, has an oblong bulbous root, sending up a naked stalk, about a foot high, terminated by a spath, protruding one or two white flowers, appearing in March.

2. The autumnum, or summer leucomin, has a large oblong bulbous root, an upright stalk, 15 or 18 inches high, terminated by many white flowers in May. 3. The automnale has a large oblong bulbous root, narrow leaves, an upright stalk, terminated by white flowers in autumn. 4. The shumosum, with flowers white within, purplish without.

LEUCOMA. See Surgery.

LEVEL, an instrument used to make a line parallel to the horizon, and to continue it out at pleasure; and by this means to find the level of objects, or the height of ascents or descents, between two or more places, for conveying water, draining, &c.

There are several instruments, of different contrivance and matter, invented for the perfection of levelling. They may be reduced to the following kinds:

Water-Level, the which shews the hori-
LEVEL.

A common level, as the name implies, is one that has a horizontal line of sight, and is used to determine the level of surfaces, such as the ground or a building. It is based on the principle that a bubble always seeks its lowest position, which is directly above the position of the instrument when it is perfectly horizontal. The instrument consists of a glass tube, usually about 6 inches long, containing a small amount of fluid, and a bubble of air. When the instrument is perfectly horizontal, the bubble is centrally located; if it is tilted in any direction, the bubble will move to one side, indicating the degree of tilt.

The level is used in construction, surveying, and various other fields to ensure that surfaces are level or to determine the gradient of slopes. It is an essential tool for ensuring accuracy in building and construction projects.

Dr. Desaguiler's machine, described in the text, is a level with a glass object-glass, which allows for precise measurements of horizontal lines. The instrument's principle is based on the fact that a horizontal line is one where the distance between two objects is constant, regardless of the observer's position.

In conclusion, the level is a fundamental instrument in the field of construction, allowing for precise and accurate measurements, ensuring the quality and safety of structures and projects. Its simplicity and effectiveness make it an indispensable tool for professionals in the construction industry.

RAW_TEXT_END
Lowered by means of a milled-headed screw N, which works through a collar in the lower end of the tube; the rest of the tube has a triangular hole through it, in which slides a bar k, which is part of the Y; O the female screw is turned in the eyepiece, and the screw works into it, so that by turning the milled head one way, the Y is raised, and by reversing the motion, it is lowered. The axis which connects the compass-box and the other apparatus, has a collar upon it just above where it enters the ball, fig. 3, which is embraced by a clamp P, fig. 6, which is closed by a screw Q, so as to hold the collar of the axis quite tight: and when the screw is turned back, its own distictity opens it so as to allow the axis of the compass-box to turn round freely within it; on the opposite side of the clamp is a projecting arm h, carrying the nut m of the screw Q, which screw works in a stud a, fixed to the upper plate G, figs. 7 and 6; by this means, when Q is loosened, the telescope can be turned quite round, but when it is fastened, it can only be moved by turning the screw Q. The level-tube Z is fastened in the same way as the telescope is, by a screw g at one end and a bar r at the other: the use of these are to adjust it so that it shall be exactly parallel to the axis of the telescope-tube. The level, as best explained by the section fig. 1, is a tube of glass s*, nearly filled with spirits of wine, but so as to leave a bubble of air in it; if the tube is of exactly the same diameter in every part, the bubble will rest in the middle of the tube when the axis is in the plane made by Ramsden, the inside of the tube is bent into a segment of a circle, 100 feet diameter, and the inside is ground, which causes the bubble to adhere together; if the tube is straight, it is liable to divide into several small ones. The internal parts of the telescope are explained in fig. 1: RR is the external tube of brass plate; within this slides another tube ss; A has two glasses v, w, screwed into the outer end, called object-glasses, and it has two divisions x, y, called diaphragm, with small holes in them; their use is to collect the prismatic rays with which the objects would otherwise be tinged; the glasses are fixed nearly in the middle of j, which turns into a pinion on the axis of the milled head T, figs. 1 and 7; by turning this, the glasses v, w, can be moved nearly to, or farther from, the eye to adjust the focus; to the tube R at y, are fixed the cross-wires, whose intersection is exactly in the centre of the tube. The manner of using these is explained in fig. 3: A is a brass box, which fits into the end of the telescope-tube, and has a perforated floor by four small screws; within this box is placed a brass plate B, carrying the wires, which are fastened by screwing four screws down upon their ends; when the plate B is in the box, a ring D is screwed in upon it, which prevents its falling out, but at the same time leaves it at liberty to move about in the box; the sides of the box, and also the telescope-tube, has four rectangular holes in it, through which four uprights project, and each in to the cross-piece B, so as to hold it in any position: these screws come through the external tube, and have square heads, to be turned by a key, so as to adjust the interactions in the centre: the box A has a female screw in the front, into which is screwed the eye-piece W; s is the tube which is screwed to the telescope; within this slides a tube, containing two glasses 4, 5; by sliding the glasses in or out of the tube 3, they can be adjusted so as to adapt their focus to the cross-wires. This eye-piece has a circumference of 36 feet 6 inches, and a diameter of 13 inches; but as it reverses the objects, it is sometimes more convenient to use the eye-piece fig. 2, which is much longer, but does not reverse objects. a is the tube which is screwed to the telescope; within this slides another tube hh, having at one end a tube dd, containing two glasses ef, and a diaphragm g, and at the other end a tube hh, containing two glasses h, and a diaphragm: s is a cap screwed on to the end to prevent the tubes coming out. When the instrument is to be carried, the level is unscrewed from the legs and packed in a case; the legs are shut up and kept so by the rings, as before described. The manner of using this instrument is as follows: When the difference of level between any two places is required, the observer with the level goes to the highest of the two, and his assistant goes to the lowest; with the common eye-piece of the telescope is put on a groove in it, in which slides a small rod carrying a round piece of wood, called a sight, which is to be observed through the telescope; the observer opens the legs of the instrument, and then sets the other end of the level next is screwed to them at E, as shown in fig. 7; the telescope is then brought nearly to a level by the screws HHHH, as before described; the screw e is then turned so as to adjust the focus, fig. 6; and the telescope is turned about, so as, at the point of the target, the clamp P is then closed, the observer looks through the telescope, and by tuning the nut 1, the focus is adjusted: the screw Q is then turned till the cross-wires are brought to coincide with the object, in an horizontal plane: he then takes his eye from the telescope, and works the screw N till he brings the bubble of air in the level-tube exactly in the middle, which shows that the telescope is perfectly horizontal; the observer then makes signals to the assistant to raise or lower the sight on the slider of the target, till it is brought to coincide with the intersection of the two cross-wires, which shows that the telescope and the sight of the target are on the same level; the height which the sight is from the ground where the target stands, deducted from the height the telescope stands from the ground, is the difference of level required.

LEVELLING, the art or act of finding a line parallel to the horizon at one or more stations, to determine the height or depth of one place with respect to another; for laying out grounds even, regulating descents, draining meadows, conducting water, &c.

Two or more places are on a true level when they are equally distant from the centre of the earth. Also one place is higher than another, or out of level with it, when it is farther from the centre of the earth; and a line equally distant from that centre in all its points, is called the line of true level. Hence, the property of a curve, which is a part of the earth's circumference, or at least parallel to it, or concentric with it, is that it may pass all its points equally distant from a, the centre of the earth, considering it as a perfect globe.

But the line of sight BDF, &c. given by the operations of level, is a tangent, or a right line perpendicular to the semidiameter of the earth at the point of contact B, rising always higher above the true line of level, the farther the distance is, called the apparent level or the true level, is the height of the apparent level above the true level, at the distance BC or BD; and if E is the excess of height at F, and GH at G, &c. the difference, it is evident, is always equal to the excess of the arc of the arch of distance above the radius of the earth.

The common methods of levelling are sufficient for laying pavements of walls, or for conveying water to small distances, &c.; but in more extensive operations, as in levelling the bottoms of canals, which are to convey water to the distance of many miles, and such like, the difference between the true and the apparent level must be taken into the account.

Now the difference CD between the true and apparent level, at any distance BC or BD, may be found thus: By a well-known property of the circle, 2AC + CD = BD; or BD − CD is the excess of the apparent over the true level, and which to an operation commonly extends, that 2AC may be safely taken for 2AC − CD = BD, without any sensible error, it will be 2AC = BD; or BD = CD, which therefore is BD or 2AC − nearly that is, the difference between the true and apparent level, is equal to the square of the distance between the places, divided by the diameter of the earth, and consequently it is always proportional to the square of the distance.

Now the diameter of the earth being nearly 7958 miles; if we first take BC = 1 mile, then the excess of becomes 1 = 7.938 miles, which is 7.903 miles, or almost 8 inches, for the height of the apparent above the true level at the distance of one mile. Hence, proportioning the distances in altitude according to the squares of the distances, the following Table is obtained, showing the height of the plane above the true level for every 100 yards of distance on the one hand, and for every mile on the other.

</table>

By means of tables of levels, we can now level to almost any distance at one operation, which the ancients could not do by a great multitude; for, being unacquainted with the correction answering to any distance, they only levelled from one 20
The operation of levelling is as follows: Suppose the height of the point A (Plate 15, fig. 153), the top of a mountain, above that of B at the foot of it, is required. Place the level along the middle distance at D, and set up pickets, poles, or staffs at A and B, which usually must attain with signals for raising and lowering, on the said poles, little marks of pasteboard or other matter. The level having been placed horizontally by the bubble, &c. look towards staff A, and cause the person there to raise or lower the mark till it appears through the telescope or sights, &c. at F; then measure exactly the perpendicular height of the point B above the point A, which suppose 3 feet 8 inches, and set it down in your book. Then turn your view the other way towards the pole B, and cause the person there to raise or lower his mark, till it appears in the visual line as before at C; and measuring the height of C above B, which suppose 13 feet, set this down in your book also, immediately above the number of the first observation. Then subtract the one from the other, and the remainder 9 feet 10 inches will be the difference of level between the places A and B, which is the height of the point A above the point B.

If the point D, where the instrument is fixed, is exactly in the middle between the points A and B, there will be no necessity for reducing the level to the true one, and the visual ray on both sides being raised equally above the true level. But if not, each height must be corrected or reduced according to its distance, before the one corrected height is doubled to the other. When the distance is very considerable or irregular, so that the operation cannot be effected at once placing of the level, or when it is required to know if there is a sufficient descent for conveying water from the spring A to the point B (fig. 154), this must be performed at several operations. Having chosen a proper place for the first station, as at F, fix a pole at the point A near the place where the first pole is to be set, and thence descend the distance to A by the level, and measure the distance from A to L, then the level being adjusted in the point L, let the mark L be raised or lowered till it is seen through the telescope or sights, &c. at those points of level, and on the staffs A and B. Then having fixed another pole at H, direct the level to it, and cause the mark G to be moved up or down till it appears through the instrument; then measure the height of the height, &c. and the distance from 1 to H, noting them down in the book. This done, remove the level forward to some other eminence as E, from whence the pole II may be viewed, as also another pole at D; then having adjusted the level to the point II, look back to the point H; and noticing the mark as before, the visual ray will give the point F; then measuring the distance HE and the height HE, note them down in the book. Then, turning the level to look at the next pole D, the visual ray will give the point D; there measure the height of E, and the distance EB, entering them in the book as before. And this proceed from one station to another till the whole is completed.

Having summed up all the columns, add those of the distances together, and the whole distance from A to B is 4735 yards, or two miles and three quarters nearly. Then the sum of the corrections taken from the sum of the apparent heights, leave the two corrected heights; the one of which being taken from the other, leaves 5 feet 11½ inches for the true difference of level sought between the two places A and B, which is at the rate of an inch and a half nearly to every 100 yards, a quantity more than sufficient to cause the water to run from the spring to the house.

Or the operation may be otherwise performed; thus: Instead of placing the level between every two poles, and taking both back-sights and fore-sights, plant it first at the spring A, and from thence observe the level to the first pole, remove it to this pole, and observe the second pole; next move it to the second pole, and observe the third pole; and so on, from one pole to another, always taking forward sights or observations only. After these, the true height and the corrected heights together, and the sum will be the whole difference of level sought.

LEVELLING-STATES, instruments used in levelling, serving to carry the marks to be observed, and at the same time to measure the heights of these marks from the ground. They usually consist each of two long wooden rulers, made to slide over one another, and divide into feet, inches, &c.

LEVER. See MECHANICS.

LEVIGATION. See PHARMACY.

LEVISANUS, a genus of the class and order pentandria monogynia. The flowers are aggregate; corolla one-leaved, superior, five-cleft; elements inserted into the base of the perianth; styles two, conjoint; seeds five or six. There are five species, shrubs of the Cape.

LEYDEN PHIAL. See ELECTRICITY.

LEYSEKA, a genus of the polygonum superbus order, in the syngenesia class of plants, and in the natural method ranking under the 49th order, composite. The receptacle is naked; the pappus paleaceous;
that of the disc plummy; the calyx scarious. There are three species, shrubs of the Cape, Liatris, being of the class and order
Syngenesio-polygamae. The calyx is oblong, inimicate, awnless, coloured down, feathered coloured; receptacle naked, hollow, dotted. There are eight species, herbs of America.

Libel, injurious reproaches or accusations written and published against the memory of one who is dead, or the reputation of one who is alive, and thereby exposing him to public contempt, censure, and ridicule.

With regard to libels in general there are, as in many other cases, two remedies; one by indictment or information, and the other by action. The former for a public offense; for every libel has a tendency to the breach of the peace, by provoking the person libelled to break it; which offence is said to be the same in point of law, whether the matter contained is true or false; and therefore it is that the defendant on an indictment for publishing a libel, is not allowed to allege the truth of it by way of justification. But in the remedy by action on the case, which is to repair the party in damages for the injury done him, the defendant may, as in other cases, spoken, justify the truth of the facts, and show that the plaintiff has received no injury at all. The chief excellence therefore of a civil action for a libel consists in this, that it not only affords a reparations for the injury sustained, but it is a full vindication of the innocence of the person traduced. 3 Black. 125.

By a late statute, the jury are acknowledged to be judges both of the law and the fact.

Libel, in the ecclesiastical court, is the declaration or charge drawn up in writing, on the part of the plaintiff, to which the defendant is answerable to.

Lobel, in the law of Scotland, signifies an indictment.

Libelula, dragon-fly, a genus of insects of the order neuroptera. The generic character is: mouth furnished with several jaws, short; wings four, extended; tail (in the male) hook-furnished.

The libelula, or dragon-flies, sometimes called by the very improper title of horse-stingers, exhibit an instance scarcely less striking than the butterfly of that strange display, in point of form under which one and the same animal is destined to appear in the different periods of its existence. Perhaps few persons not particularly conversant in the history of insects, would imagine that these highly brilliant and lively animals, which may be seen flying with such strength and rapidity round the meadows, and pursuing the smaller insects with the velocity of a hawk, had once been inhabitants of the wa- ters in which they had resided for a very long space of time in that element before they assumed their flying form. Of the libelula there are many different species, both native and exotic. The most remarkable of these various species is the libelula varia, or great variegated libelula. This insect makes its appearance principally towards the decline of summer, and is an animal of singular beauty. Its general length is about three-quarters of an inch; and when expanded, measure near four inches from tip to tip; the head is very large, and affixed to the thorax by an extremely slender neck; the eyes occupy by far the greatest part of the head, and are of a purplish blue color. The face is furnished with a little stumpy hair; the thorax of the same colour, but marked by longitudinal black streaks; the body, which is very long, slender, and subcylindrical, is black, with rich variegations of bright blue, and deep grass green; the wings are perfectly transparent, strengthened by very numerous black reticulated fibres, and exhibit a strong iridescent appearance, according to the various reflections of light. The abdomen is marked this tip by a small oblong square black spot on the outer edge; the legs are black, and the tail is terminated by a pair of black fornicated processes, with an intermediate shorter one of similar colour. Sometimes this insect varies; the spots or marks on the abdomen and thorax being red or red-brown instead of green.

The female libelula deposits or drops her eggs into the water, which sticking to the bot- tom, are hatched, after a certain period, into hexapode flatfish larvae or caterpillars, of a very singular and disagreeable aspect. They cast their skins several times before they ar- rive at a certain size, and then assume a brown colour. The rudiments of the future wings appear on the back of such as are advanced to what may be called the pupa or chrysalis state, in the form of a pair of oblong scales or ocellae, and the head armed with a most singular organ for seizing prey, viz, a kind of proboscis, of a flattened form, and furnished with a joint in the middle, the end being much dilated, and armed with a pair of large hooks or spines. This proboscis, when the animal is at rest, is folded or turned up in such a manner as to lay over the face like a mask; but when the creature sees any insect which it means to attack, it springs suddenly forwards, and by stretching forth the jointed proboscis, readily obtains its prey. They continue in their larva and pupa state for two years, when, having attained their full size, they prepare for their flight, by steeping up the stem of some water-plant, and clasping it with their feet, they make an effort, by which the skin of the back and head is forced open, and the inclosed libelula gradually emerges. The wings, at first, are rather transparent; but, except, like those of butterflies, are very short, tender, and contracted, all the ramifications or fibres having been compressed within the small compass of the oblong scales on the back of the larva, or pupa; but in the space of about half an hour, they are fully expanded, and have acquired the solidity and strength necessary for flight. This curious process of the evolution or birth of the libelula generally takes place in the morning, and during a clear sunshine. The remaining part of the animal's life is but short in comparison with that which it passed in its aquatic state, the floss of the close of autumn destroying the whole race. They are also the prey of several sorts of birds.

The libelula depressa is a smaller or shorter species than the preceding, though with a considerably broader body in proportion. The head is bright sky-blue, with the sides of the body yellow, its under side, a fine brown or bay, with yellow sides also. The wings in both sexes are transparent, ex-

cept at the shoulders, where they are each marked by a broad red or patch of brown with a stripe of yellow; the tips of each wing have a small oblong square black spot on the outer margin. The larva of this species is of a shorter form than that of the preceding, and is of a greenish-brown colour.

The libelula virgo is one of the most ele- gant of the European insects. It is much smaller than the libelula varia, and is distinguis-
ished by its very slender, long, cylindrical body, which, as well as the head and thorax, is usually either of a bright but deep golden green, or else of a deep gilded blue. The wings are transparent at the base and tips, but are each marked in the middle by a very large oval patch or bed of deep blackish or violet blue, accompanied by iridescent lines according to the direction of the light; sometimes the wings are entirely violet-black, without the least appearance of transparency either at the base or tips; and sometimes they are altogether transparent, without any appearance of the violet-black patch which usually proves the deficiency; and lastly the insect sometimes appears with transparent wings, but shaded with a strong east of gilded greenish brown, each being marked by a small white speck at the extreme edge.

A much smaller species than the preceding, and equally common, is the libelula piella of Linnaeus. This varies much in colour, but is generally of a bright and beauti-
ful olive, sometimes tinted black with black bars on the joints, and with the thorax marked by black longitudinal stripes. The wings are transparent, and each marked near the tip with a small oblong-square black marginal spot.

The exotic libelulae are very numerous. Among the most remarkable may be num-
bered the L. lucicrida. It is a native of the type of Good Hope, and is distinguished by the excessive length of its slender body, which measure not less than five inches and a half in length, though scarcely exceeding the tenth of an inch in diameter. The wings are transparent, or of a slender or narrow shape, having the tints of this species usual in form, and measure five inches and a half in extent from tip to tip. The colour of the head and thorax is brown, with a yellowish stripe on each side, and the body is of a deep mazarine-blue. See Blackburn, Nat. Hlst. figs. 250, 251.

LIBERTUS, in Roman antiquity, a per-
son who from being a slave, had obtained his freedom. The difference between the li-
bertus and libertini was this: the liberti were such as had been actually made free them- selves, and the libertini were the children of such persons.

LIBRA, in astrology, one of the twelve signs of the zodiac, the sixth in order; so called because when the sun enters it, the days and nights are equal, as it weighed in a balance.

Authors enumerate from ten to forty-nine stars in this sign.

LIBRA, in Roman antiquity, a pound weight; also a coin, equal in value to twenty denarii.

LIBRATIONS, in astronomy, an apparent irregularity of the moon's motion, whereby it seems to librate about her axis, sometimes from the east to the west, and now and
then from the west to the east; so that the parts in the western limit or margin of the moon sometimes recede from the centre of the disk, and sometimes move towards it, by which means they become alternately visible and invisible to the naked or, if engaged, by the eye.

Libration of the earth, is sometimes used to denote the parallelism of the earth's axis, in every part of its orbit round the sun.

Licence, in law, an authority given to a person to do some lawful act.

A licence is a written power, and therefore cannot be transferred to another. If the person licensed abuse the power given him, in that case he becomes a trespasser.

Licentiate, one who has obtained the degree of a licentiate. The greatest number of the officers in justice in Spain are distinguished by no other title but that of licentiate. In order to pass licentiate in common law, civil law, and physic, they must have studied seven years; and in divinity, ten. Among us, a licentiate usually means a physician who has a licence to practise, granted by the college of physicians, or the bishop of the diocese.

Lichen, freecor, a genus of the natural order of Algae, in the Cryptogama class of plants. The male receptacle is roundish, somewhat plain and shining. In the female the leaves have a farinaceous or merely substance scattered over them. There are about 216 species, all found in Britain. Among the most remarkable are the following:

1. The geographicus; it is frequent in rocks, and may be readily distinguished at a distance. The crust and ground is of a bright greenish-yellow colour, sprinkled over with numerous plain black tubercles, which frequently run into another, and form lines resembling the rivers in a map, from which last circumstance it takes its name.

2. The calcareous, or black-polished dyer's lichen, is frequent on calcareous rocks; and has a hard, smooth, white, stony, or tarsaceous crust, cracked or tesselated on the surface, with black tubercles. Dillenius relates, that this species is used in dyeing, in the same manner as the tarsaceous after-menioned.

3. The venous, or red spangled tarsaceous lichen, has a hard tarsaceous crust, cracked and tesselated on the surface, of a pale yellow colour, which is frequently seen when dry. The tubercles are of a blood-red colour at top, their margin and base of the same colour as the crust. The texture and appearance of this (according to Mr. Lightfoot) indicate that it would answer the purposes of dyeing as well as some others of this tribe, if proper experiments were made.

4. The candelarius, or yellow farinaceous lichen, is common upon walls, rocks, boards, and old pales. There are two varieties. The first has a farinaceous round orange figure, covered with numerous small greenish-yellow or olive shields, and grows commonly upon old boards. The other has a smooth, hard, circular crust, wrinkled and tuberculated at the circumference, which adheres closely to rocks and stones. In the centre are numerous shields of a deeper yellow or orange colour, which, as they grow old, swell in the middle, and assume the figure of tubercules. The inhabitants of Smaland in Sweden scrape this lichen from the rocks, and mix it with their tallow, to make golden candles to burn on festival days.

5. The tarenten, or large yellow-saucered dyer's lichen, is frequent on rocks, both in the Highlands and Lowlands of Scotland. Its crust is white or greenish white, and has a rough warted surface. The shields are yellow or buff-coloured, of various sizes, from that of a pin's head to the diameter of a silver penny. Their margin is often of the same colour with the crust. This lichen is much used by the Highlanders for dyeing a fine claret or pantaloour colour. For this purpose, after scraping it from the rocks, and cleaning it, they steep it in urine for a quarter of an year. Then taking it out, they make it into cakes, and hang them up in bags to dry. These cakes are afterwards pulverized, and the powder is used to impart the colour with an addition of alum.

6. The parcellus, or crawfish-eye lichen, grows upon walls and rocks, but is not very common. The crust spread closely upon the place where they grow, and cover them to a considerable extent. They are rough, tarsaceous, and ash-coloured, of a tough corneous substance, with numerous white or grayish, or cracked, having white or ash-coloured, shallow, plain discs, with obtuse margins. This is used by the French for dyeing a red colour.

7. The saxatilis, or grey-blue pitted lichen, is very common upon trunks of trees, rocks, tiles, and old wood. It forms a circle two or three inches diameter. The upper surface is of a blue grey, and sometimes of a whitish ash-coloured, uneven, and full of numerous small pits or cavities; the under sides is black, and covered all over, even to the edges, with short simple hairs or radicles. A variety sometimes occurs with leaves tinged of a red or purple colour. This is used by fishermen and other small birds in constructing the outside of their curiously formed nests.

8. The omphalodes, or dark-coloured dyer's lichen, is frequent upon rocks. It forms a thick, widely expanded crust of no regular figure, composed of numerous irregular leaves of a fuscous or purple-coloured, divided into small segments. The margins of the shields are a little crivelled and turned inwards, and their outside ash-coloured. This lichen is much used by the Highlanders for dyeing a dark purple colour. They steep it in urine for a considerable time, till it becomes soft and like a paste; then, forming the paste into cakes, they dry them in the sun, and preserve them for use in the manner already related of the tarenten.

9. The parietinus, or common yellow wall-lichen, is very common upon walls, rocks, tiles of houses, and trunks of trees. It generally spreads itself in circles of two or three inches diameter, and is said to dye a good yellow or orange-colour with alum.

10. The Islandicus, or eated alcedin lichen, grows on many mountains both of the Highlands and Lowlands of Scotland. It consists of nearly erect leaves about two inches long, when dry, and smooth, but soft and plant when moist, variously divided without order into broad distant segments, bifid or trifid at the extremities. The upper or interior surface of the leaves is crimson, or purple shining, but red at the base; the under or exterior surface is smooth and whitish, a little pitted, and sprinkled with very minute black warts. The margins of the leaves and all the segments from bottom to top, are ciliated with small, short, stiff, hair-like spines, of a dark chestnut-colour, turning towards the upper side. The shields are very rarely produced. Made into broth or gruel, it is said to be very serviceable in coughs and consumptions; and, according to Haller and Scopoli, is much used in these complaints in Vienna.

11. The pulmonarius, or lung-wort lichen, grows in shady woods upon the trunks of old trees. The leaves are as broad as a man's hand, of a kind of leather-like substance, hanging loose from the trunk on which it grows, and laciniated into wide angular segments. Their natural colour, when fresh, is green; but in drying, they turn first to a glaucous and afterwards to a fuscous colour. It has an astringent, bitter taste; and, according to Gmelin, is boiled in ale in Siberia, instead of hops. The antients used it in coughs and asthma, &c. but it is not used in modern practice.

12. The cactarius, or heaked lichen, grows sometimes upon trees, but more frequently upon rocks, especially on the sea-coasts, but is not very common. It is smooth, glozy, and whitish, producing a variety of the same colour as the leaves, very near the summits of the segments, which are acute and rigid, and, being often reflected from the perpendicular by the growth of the shields, appear from under the leaves to be broken back. This will dye a red colour; and promises, in that intention, to rival the famous lichen roccola or argol, which is brought from the Canary Islands, and sometimes sold at the price of 80l. per ton. It was formerly used instead of starch to make hair-power.

13. The prunastri, or common ragged hoary lichen, grows upon all sorts of trees; but it is generally most white and hoary on the sloe and old palm trees, or upon old pales. This is the most variable of the whole tribe of lichens, appearing different in figure, magnitude, and colour, according to its age, place of growth, and sex.

14. The juniperinus, or common yellow tree-lichen, is common upon trunks and branches of trees, and also upon the house walls and in the stables. Linnaeus says it is very common upon the juniper. The Gothland Sweeds dye their yarn of a yellow colour with it, and give it as a specific in the jaundice.

15. The saccaria, or ash-coloured ground liverwort, grows upon the ground among stones.
mass, at the roots of trees in shady woods, and is frequent also in heaths and stony places. The leaves are large, gradually divided towards the extremities, and divided into roundish, elevated lobes. Their upper side, in dry weather, is ash-coloured; in rainy weather, of a dull fuscous-green colour; their under-side white and hoary, having many thick downy nerves, from which descend numerous long, white, pencil-like radicles. The petiole, or shi-lis, grow at the extremities of the elevated lobes, shaped like the human nail; of a roundish oval form, convex above, and concave beneath; of a chocolate colour on the upper side, and the same colour with the leaves on the under. There are two varieties, the one called redlisch, and the other many-fingered, ground-liverwort. The former is more common than the other. This species has been rendered famous by the celebrated Dr. Mead, who asserted that it was an infallible preventative of the dreadful consequence attending the bite of a mad dog.

16. The aphthous, or green ground lvi-erwort with black warts, grows upon the ground at the roots of trees in woods, and of such places in garden cunt places. It differs very little from the foregoing, and according to some is only a variety of it. Linnaeus informs us, that the country-people of Upland in Sweden give an infusion of this lichen in milk to children that are troubled with the disorder called the thush or aphthous, which induced that ingenious naturalist to be-tow upon it the trivial name of aphthous. The same writer also tells us, that a decoction of it is used for purges upwards and downwards, and will destroy worms.

17. The coccurus, or scarlet-tipped cuplichen, is frequent in moors and heaths. It has in the first state a granulated crust for its ground, which is afterwards turned into small facinated leaves, green above, and hoary underneath. The plant assumes a very different aspect, according to the age, situation, and other accidents of its growth, but may be in general distinguished by those tubercles, which are fungous tubercles of a fine scarlet colour, placed on the rim of the cup, or on the top of the stalk. These tubercles, steeped in an alkaline liquor, are said to dye leather and yarn of a yellow.

18. The rangierius, or rein-deer lichen, is frequent in woods, heaths, and mountainous places. Its general height, when full-grown, is about two inches. The stalk is hollow, and very much branched from bottom to top: the branches are divided and subdivided, and at last terminated by two, three, four, or five very fine, short, nobby horns. The axile of the branches are often perforated. The whole plant is of a hoary white or grey colour, covered with white farinaeous particles, light and brittle when dry, soft and elastic when moist. The fructifications are very minute, round, fuscous, or red-flushed brown tubercles, which grow on the very extremities of the finest branches; but these tubercles are very seldom found. The plant seems to have no folaceous ground for the base, nor scarcely any visible roots. It is equally common and no less luxuriant, wherever it grows so luxuriant that it is sometimes found a foot high. There are many varieties of this species, of which the principal is the syriaticus, or brown-tint rein-deer lichen. The most remarkable difference between them is, that the syriaticus turns fuscous by age, while the other always continues white.

19. The pulicat, or officinal lichen lichen, grows upon the branches of old trees, but is not very common. The stalks are a foot or more in length, rigid, and string-shaped, very irregularly branched, the branches entangled together, of a cinereous or ash-coloured, brittle and stringy if doubled short, otherwise tough and pliant, and hang pendent from the trees on which they grow. The shields grow generally at the extremities of the branches, are nearly flat, or slightly concave, thin, ash-coloured above, pale-brown underneath, and radiated with fine rigid fibres. As the plant grows old, the branches become covered with a white, rough, warty crust; but the young ones are destitute of it. It was formerly used in the shops as an antiprotogot against haemorrhages, and to cure rup-atures; but is out of the modern practice. Linnaeus informs us, that the Laplanders apply it to their feet to relieve the excoriations occasioned by much walking.

20. The barbus, or beard lichen, grows upon the branches of old trees in thick woods and pine-forests. The stalks or strings are slightly branched and pendent, from half a foot to two feet in length, little bigger than a tailor's button, roundish, cylindrically jointed towards the base; but surrounded everywhere else with numerous horizontal capillary fibres, either simple or slightly branched. Their colour is a white, greyish, or brown, which has an astrignent quality. When steeped in water, it acquires an orange colour; and, according to Dillenius, is used in Pennsylvania for dyeing that colour.

21. The vulpanicus or gold wry lichen, grows upon the trunks of old trees, but is not very common. It is produced in erect tufts, from half an inch to two inches in height, of a fine yellow or lemon-coloured, which readily discovers it. The filaments which compose it are so numerous as to make the whole cly-ndrically jointed towards the base; but surrounded everywhere else with numerous horizontal capillary fibres, either simple or slightly branched. Their colour is a white, greyish, or brown, which has an astrignent quality. When steeped in water, it acquires an orange colour; and, according to Dillenius, is used in Pennsylvania for dyeing that colour.

LICONIA, in botany; a genus of the di-尼亚 order, belonging to the pentandra class of plants. There are five petals inlaid in the pit of the nectararium at its base; the capelline is bilocular and sepal-bearing.

JUCULA, a genus of the nat. order of palm. The flowers are all hermaphroditic, cal. and cor. three-parted; nect. siphonid. There is one species.

LIEUTENANTS, Lords, of counties, are officers who, upon any invasion or rebellion, have power to raise the men in 11, to give commissions to colonels and other officers, to arm and form them into regiments, troops, and companies. Under the lords-lieutenants, are deputy-lieutenants, who have the same power; these are chosen by the lords-lieutenants, out of the principal gentlemen of each county, and presented to the king for his approbation. LIEUTENANTS, Officers of the army, who are attached to the expectation of the life. Life Annuit, annually payments, to continue during any given life or lives; the value of an annuity is the sum which would be sufficient (allowing for the chance of the life failing) to pay the annuity without loss; and supposing money to bear no interest, the value of an annuity of 11. is said to be equal to the expectation of the life. Thus it will be found by the table given under the article Expectation of Life, that the expectation of a life aged 20 years, is twenty years; or, in other words, that a set of lives at this age, will, one with another, enjoy twenty-three years each of existence, some of them enjoying a duration as much longer as others fall short of. Therefore, supposing money to bear no interest, 231. in hand for each life would be sufficient to pay to any number of such lives 11. per annum, for their whole duration; or, in other words, 231. is, on this supposition, the value of a life aged forty. But if any improvement is made whereby putting interest, the sum just mentioned will be more than the value, because it will be more than sufficient to pay the annuity; and it will be as much more than sufficient as the improvement or interest made. If it is greater than twenty-three years, the man himself in possession of 231., 10s. 6d. or of 311., 2d. more than is sufficient to pay the remainder of the annuities, though he should make no further improvement of the purchase money. At whatever rate of interest the money is improved, there must be a surplus; and if it is fully improved at 6%. per cent., it will be found that 111. 16s. 8d. for each annuity, will be sufficient (instead of 231.) to make all the annual payments; or, if it may be improved at 6%. per cent., 10s. 1d. will be sufficient.

Many persons have fallen into an error with respect to the value of life-annuities, by considering the same as the same as the value of an annuity certain for a number of years equal to the life of the life. The inaccuracy of this mode of computation arises from the difference between the value of a certain number of payments to be made every year regularly till the term is completed, and the value of the same number of payments to be made at greater distances of time from one another, and not to be made till many years after the expiration of the term equal to the expectation of the life.

The true method of computing the values of life-annuities cannot be more clearly expressed than as it is given in "The Doctrine of Annuities and Assurance Rates and Survivalship, by William Morgan."—Was it certainly that a person of a given age would live to the end of a year, the value of an annuity of 11. on such a person that would increase in a year to the value of a life one year older, together with the value of the single payment of 11. to be made at the beginning of a year; and if this increased together with the value of a life aged one year older than the given life, multiplied by the value of 11. payable at the end of a year. The value of a life one year older than the given life N, and the value of 11. 20

5
It is unnecessary to insert a Table of the values of the longest of two lives, as it may be easily found from the values given in the above tables by the following general rules:

"From the sum of the values of the single lives subtract the value of an annuity on the joint lives, and the remainder will give the value of an annuity of any desired continuance of the longest of two such lives."

Example. What is the value of an annuity on the longest of two lives whose ages are thirty and forty?

By Table I. the value of a single life of 30 is 13.672, and by the same Table the value of a single life of 40 is 11.837. Their sum therefore is 25.509, from which 5.576 (the value of the joint lives of 30 and 40 by Table I.) being subtracted, leaves 19.933 for the number of years purchased.

The value of an annuity on three joint lives may be found from the preceding tables, by the following rule:

"Let A be the youngest, and C the oldest of the three proposed lives. Take the value of the two joint lives B and C, and find the age of a single life of the same value. Then find the value of the joint lives A and D, which will be the value of the annuity in question, multiplying the table which come nearest to them, gives 8.216 for the value sought.

The value of three joint lives being known, the value of the longest of any three lives may be computed by the following rule:

"From the sum of the values of all the single lives, subtract the values of all the joint lives combined two and two. The difference will give the value of the three joint lives; and this last sum will be the value of the longest of the three lives."

Example. The sum of the values of three single lives whose ages are 20, 30, and 40, is 10.363 (by Table III). 38.916. The value of two joint lives, whose ages are 30 and 40, is 9.576, and that of one joint life whose ages are 20 and 30, is 11.021. The sum of these three values is 30.920. This sum subtracted from 38.916, leaves 8.063, which remainder added to 8.216, (the value of the three joint lives in the last example), gives 16.885, the value of the longest of the three lives."

The solutions of the following Problems, in addition to the rules already given, will comprehend all the cases which most commonly occur relating to the values of annuities on lives or survivals.

PROB. I. To determine the value of an annuity on a given life for any number of years.

Solution. Find the value of a life as many years older than the given life as are equal to the term for which the annuity is proposed. Multiply this value by 11, payable at the end of this term, and also by the probability that the life will continue so long. Subtract the product from the present value of the given life, and the remainder multiplied by the annuity will be the answer.

Example. Let the annuity be 20l. the age of the given life 33 years, and the term proposed 14 years. The value of a life aged 40 years (or 14 years older than the given
*life*, appears by Table I, to be 10.443. The value of 17, payable at the end of 14 years (see Table III. of *Annuity*), is 50,006, and the probability that the life will exist so long, (See *Expectation of Life*) is 2214.

These three values multiplied together each other, produce 12.502 (the present value of the given life by Table I), we have 8.641, and this remainder multiplied by 20, gives 1627.16d. 4d. for the value required.

In a similar manner the value of an annuity for any given term, upon two joint lives, may be determined.

**Phon. II.** To find the value of an annuity certain for a given term after the extinction of any given life or lives.

**Solution.** Subtract the value of the life or lives from the perpetuity, and reserve the remainder. Then say, as the perpetuity, is to the present value of the annuity certain, so is the said reserved remainder, to a fourth proportional, which will be the number of years purchase required.

**Example.** A and his heirs are entitled to an annuity certain for 14 years, to commence at the death of B, aged 35. What is the present value of this annuity at interest? By Table I. the value of the life of B is 12.502, which subtracted from 20, the perpetuity, leaves 7.498 for the remainder to be reserved. Then, as 20, is to 9.898 (the value of an annuity certain for 14 years), so is 7.498 (the reserved remainder), to 5.7107, the number of years purchase required.

**Phon. III.** To find the value of an annuity for a term certain, and also for what may happen to remain of a given life or lives after the expiration of the term.

**Solution.** Find the value of a life or lives as many years older than the given life or lives as are equal to the term for which the annuity certain is proposed. Multiply this value by 17, payable at the end of the given term, and also by the probability that the given life or lives will continue so long. Add the product to the value of the annuity certain for the given term, and the sum will be the answer.

**Example.** Let the value be required of an annuity certain for 14 years, and also for the remainder of a life now aged 35 after the expiration of this term. By Table I. the value of A's life at 39 (or 14 years older than the given life) is 10.443. The value of 17, payable at the end of 14 years, is 30,008, and the probability that the life will exist so long is 4.918. These three numbers multiplied together produce 3,861, which being added to 9.898, the value of an annuity certain for 14 years (see *Annuities*), becomes equal to 13,759, the number of years purchase required.

**Phon. IV.** To determine what annuity any given sum will purchase during the joint lives of two persons of given ages, and also during the life of the survivor, on condition that the annuity shall be reduced one-half at the extinction of the joint lives.

**Solution.** Let twice the given sum be divided by the sum of the two single lives, and the quotient will give the annuity to be paid during the joint lives; one-half of which is therefore the annuity to be paid during the remaining of the surviving life.

**Example.** A aged 27, and B aged 33, are desirous of sinking 1000l. in order to receive an annuity during their joint lives, and also another annuity of half the value during the remaining of the surviving life. It is required to determine what annuities should be granted them under those circumstances. By Table I. the value of a life of 27 is 13.977, and the value of a life of 35 is 12.502. The present value of this sum, divided by 20, gives 25.870 (the sum of the values of the two lives), gives 77.282/ for the annuity to be granted during the joint continuance of the lives; and its half, or 38.41/1, is the annuity to be paid the survivor.

**Phon. V.** If is of a given age, will, if he lives till the decease of A, whose age is also given, become possessed of a perpetual annuity, or of an estate of a given yearly value; to find the worth of his expectation in present money.

**Solution.** Find the value of an annuity on two equal joint lives whose common age is equal to the age of the oldest of the two proposed lives, which value subtract from the perpetuity, and divide the remainder by 20, or the expectation of the younger of the two lives, is to that of the older, so is the said half remainder, to a fourth proportional; which will be the number of years purchase required.

**Example.** If is 50, and B 20, the difference will be 30, the half of which is 15. Therefore as 15 is to the expectation of A is 28.27, the expectation of B, so is 15, to 4.119, which being multiplied by 50, the given annuity, we have 205.60l. for the required value of B's expectation.

If the age of B had been 20, and that of A 30 years, then to 4.119, the value just found, add the value of the joint lives, which, by Table I, is 10.707, and the sum is 14.826. Which subtracted from the perpetuity, and the remainder multiplied by 20, gives 226.7l. for the required value in this case.

**Life Estates** are of two kinds, such as are created by the act of the parties, or such as are created by the operation of the law, as estates by curtesy or dower. 2 Black. 190.

Estates for life, created by deed or grant, are, where a lease is made of lands or tenements to a man, to hold for the term of his own life, or for that of another person, or for more lives than one; in any of which cases, he is called tenant for life: only when he holds the estate by the life of another, he is usually termed tenant pur autre vie, for another's life.

Estates for life may be created not only by the express terms before-mentioned, but also by a general grant, without defining or limiting any specific estate. 2 Black. 121.

If such persons, for whose life any estate shall be purchased, shall survive themselves five years, and no proof made of the lives of such persons, in any action commenced for the recovery of such tenements by the lessees or reversioners, the persons upon whose lives such estate depended, shall be accounted as dead; and the judges shall direct the estate to pass to the surviving consequent heirs. 19 Car. II. c. 6.

**Liggament.** See Anatomy.

**Ligature.** See Surgery.

**Light.** See Optics.

**Lightfootia.** a genus of the class and order polignydia oboe. The cal, is four-leafed; cor. none; lem., and stigma sessile; berry umbilicated. There are three species, shrubs of the E. Indies.

**Lightning.** See Electricity.

**Ligusticum*, lovage; a genus of the dianyca, in the pentandria class of plants; and in the natural method ranking under the 45th order, umbellate. The fruit is obovate, and quinquedactyl on each side; the florets are equal; the petals involuted or rolled inwards, and entire. There are eight of the fruits remarkable are the lovage, the levisticum, or common, and the Scoti- cum, or Scots, lovage. The first is a native of the Appenine mountains in Italy. The second is a native of Scotland, and grows near the sea in various parts of the country.

The root of the first species agrees nearly in quality with that of angelica: the principal difference is, that the lovage-root has a stronger smell, and a somewhat less pungent taste, accompanied with a more durable sweetness, the seeds being rather warmer than the root; but although certainly capable of being applied to useful purposes, this root is not regarded in the present practice. The leaves of the second are sometimes eaten raw, as a salad, or boiled as greens, by the inhabitants of the Hebrides. They give an infusion of the leaves in whey to calves, to purge them.

**Ligustrum. gregis.** a genus of the natural order, in the umbellaria class of plants; and in the natural method ranking under the 44th order, sesquiped. The corolla is quadrifid; the berry tetraspernum. There are three species; of the common there are two varieties, the deciduous and the evergreen. They are hardy plants, rising from ten to fifteen feet high. They are easily propagated by seed, layers, suckers, or cuttings. They are used for making hedges. The purple colour upon cards is prepared from the berries. With the addition of alum, these berries are said to dye wool and silk of a good and durable green; for which purpose they must be gathered as soon as they are ripe, and are then a bitter and slightly astrigent. Oxen, goats, and sheep, eat the plant; horses refuse it.

**Light.** in geometry, &c. denotes the same with similar. See Similar.

**Lilac.** in botany, a genus of trees, otherwise called Syringa. See Syringa.

**Lilabyte.** This stone appears to have been first observed by the abbe Foda, and to have been then described by De Bom. Lithio it has only been found in Moravia
in Germany, and Sudermannia in Sweden. There it is mixed with granite in large amorphous masses. It is composed of thin plates, easily separated, and not unlike those of mica. Not easily pulverised. Specific gravity 2.8-3.0. Colour ochreous, to yellow, purple, blue; of the thin plates, silvery white. Powder white, with a tint of red. Before the blowpipe, it frosts, and melts easily into a white semi-translucent enamel, full of bubbles. Dissolves in borax with effervescence, and communicates no colour to it. Effervescences slightly with soda, and melts into a mass spotted with red. With microcosmic salts it gives a pearl-coloured globule.

This stone was first called lillite from its colour, that of the lily. Klaproth, who discovered its component parts, gave it the name of leptolite.

It is composed of 63 silica
28 aluminium
10 potass
3 fluors of lime
3 oxides of manganese
1 oxide of iron

100.

LILLIUM, the lily; a genus of the monogynia order, in the hexantheria class of plants; and in the natural method ranking under the 10th order, corona. The corolla is hexa- petalous, andringed with a longitudinal nectariferous line or furrow; the capsules connected by small cancelled hairs. There are eleven species; all of them bulbous-rooted, herbaceous, flower perennial, ri- sing with erect stalks, 5-7 feet high, garnished with long narrow leaves, and terminated by fine clusters of large bell-shaped, hexa-petalous flowers of great beauty, of white, red, scarlet, orange, purple, and yellow colours.

All the species are propagated by sowing the seeds; and if care is taken to preserve these seeds from good flowers, very beautiful varieties are often produced.

The roots of the white lily are emollient, maturating, and suppulsive, and are used externally in catarrhal cases for these purposes with success. The common form of applying them is, boiled and bruised. Gerard recommends them internally against dropsies.

The Kambischaten, or Kambischata lily, called there sarame, makes a principal part of the food of Kambischats. Its roots are gathered by the women in August, dried in the sun, and laid up for use: they are the best bread of the country; and after being baked are reduced to powder, and serve instead of flour in soups and several dishes. They are sometimes washed, and eaten as potatoes; are extremely nourishing, and have a pleasant bitter taste. Our navigators boiled and ate them with their meat. The natives often parch it, and heat it up with several sorts of berries, so as to form of it a very agreeable confection. Providentially it is an universal plant there, and all the grounds bloom with its flower during the season. Another happiness resultant with this, while it is scarce, the sarame is plentiful; and when there is a dearth of this, the rivers pour in their provisions with redoubled pro- fusion. It is not to the labours of the females alone that the Kambischats are indebted for these roots. A species of mouse saves them a great deal of trouble. The sarame forms part of the water provisions of this little animal: they not only gather them in the proper season, and lay them up in their magazines, but those who possess the requisites of bringing them out in sunny weather to dry them, lest they should decay. The natives search for their hoards; but with prudent tendencies leave part for the owners, being unwilling to suffer such useful caterers to perish.

LIMAX, the slug, or naked snail; a ge- nus of insects belonging to the order of vernes mollusca. The body is oblong, fitted for crawling, with a kind of muscular coat on the upper part, and the body is plain. They have four tentacula, or horns, situated above the mouth, which they extend or retract at pleasure. This reptile is always destitute of shell; but besides that its skin is more clammy, and of a greater consistency, than that of the snail, the black naked slug is a furrowed cloak, almost as thick and as hard as leather, under which it withdraws its head as within a shell. The head is distinguished from the body by a black line, when the head and two thirds of the stone are found; which is a small pearedl and sand stone, of the nature of limestones: according to a popular opinion, it cures the tertian ague, if fastened to the patient's arm, and carried above on every where chimmy and shining marks of their passage. They de- posit their eggs in the earth. There are eight species, distinguished entirely by their colour: as the black slug, the white slug, the red slug, the ash-coloured slug, &c. The black slug is hermaphroditic. A black slug, powdered over with snuff, salt, or sugar, falls into convulsions, casts forth all its foam, and dies.

LIME, one of those earthy substances, which exist in every part of the known world. It is found pure in limestone, marble, and chalk. None of these substances are lime, but are capable of becoming so by burning in a white heat.

Lime may be so obtained perfectly pure by burning, than a crystalized limestone called calcareous spars, which are perfectly white and transparent, and also by burning some pure white marbles. It may be procured also in a state of pure white, by dissolving in a strong acid, filtrating the solution, mixing it with ammonia as long as a white powder continues to fall, and fil- trating again. The liquid is now to be mixed with a solution of carbon of soda: the powder which falls being washed and dried, and heated violently in a platinum crucible, is pure lime.

Pure lime is of a white colour, moderately hard, but easily reduced to a powder. It has a hot burning taste, and in some measure corrodes and destroys the texture of those animal bodies to which it is applied. Its specific gravity is 2.3. It tingles vegetable blue, and at last converts them to yellow.

If water be poured on newly burnt lime, it swells and falls to pieces, and is soon re- duced to a very fine powder. In the mean- time so much heat is produced, that part of the water lies off in vapour. If the quantity of lime shaded (as this process is termed) be great, the heat produced is sufficient to set fire to combustibles. In this manner, vessels loaded with lime have sometimes been burnt. When great quantities of lime are placed in a dark place, and set fire to a light, Mr. Pelletier has observed. When shaded lime is weighed, it is found to be heavier than it was before. This additional weight is owing to the combina- tion of part of the water with the lime; which water may be recovered by the application of a red heat; and by this pro- cess the lime becomes just what it was before being shaded. Hence the reason of the heat evolved during the shading of lime. Part of the water contents with the lime, and thus becomes solid; of course it parts with its caloric of fluidity, and probably also with a considerable quantity of caloric, which exists in water even when in the state of ice; for when two parts of lime and one part of ice (each at 32°) are mixed, they combine rapidly, and their temperature is elevated to 212°. The elevation of temperature during the shading of barytes and strontian is owing to the same cause.

The smell perceived during the shading of lime is owing to a part of that earth being elevated along with the vapour of the water; as evidently appears from this circumstance, that vegetable spices exposed to this vapour are converted to green.

Limestone and chalk, though they are capable of being converted into lime by burning, possess hardly any of the properties of that active substance. They are tasteless, scarcely soluble in water, and do not perceptibly act on animal bodies. Now, what are the new properties of lime obtained by what alteration does it undergo in the fire?

It had been long known, that limestone loses a good deal of weight by being burned or calcined. It was natural to suppose, therefore, that something is separated from it during calcination. Dr. Black, of Edin- burgh, published in 1756, those celebrated experiments on this subject, which form so brilliant an era in the history of chemistry. He first ascertained, that the quantity of air in lime, evolved from its calcination is not nearly equal to the weight which it lost. He concluded in consequence, that it must have lost something else than mere water. What this could be, he was at first a loss to conceive; but recollecting that Dr. Hales had proved, that limestone, during its solution in acids, emits a great quantity of air, he conjectured that this might probably be what it lost during calcination. He calcined it accordingly, and applied a pneumatic apparatus to receive the product. He found his conjecture verified; and that the air and water which separated from the lime were together precisely equal to the loss of weight which it had sustained. Lime, therefore, owes its new properties to the loss of air; and limestone differs from lime merely in being combined with a certain quantity of air: for he found that, by restoring again the same quantity of air to lime, it was converted into limestone. This air, because it existed in lime in a fixed state, he called fixed air. It was afterwards examined by Dr. Priestley and other philosophers, who found it possessed of peculiar properties, and to be that species of gas now known by the name of carbonic acid gas. Lime
then is a simple substance, and limestone is composed of carbonic acid and lime. It heat separates the carbonic acid, and leaves the lime in a state of purity. See Aq.

When lime is exposed to the open air, it gradually absorbs moisture, and falls to powder; after which it soon becomes saturated with carbonic acid, and is again converted into carbonat of lime or unburnt limestone.

Water, at the common temperature of the atmosphere, dissolves about 0.002 parts of its weight. This solution is called lime-water. It is limpid, has an acrid taste, and changes vegetable blue colours to green. One ounce troy of lime-water contains about one gram of lime. It is usually formed by throwing a quantity of lime in powder into pure water, allowing it to remain for some time in a close vessel, and then decanting the transparent solution from the undissolved lime. When lime-water is exposed to the air, a stony crust soon forms on its surface, composed of carbonat of lime; when this crust is broken it falls to the bottom and another succeeds it; and in this manner the whole of the lime is soon precipitated, by absorbing carbonic acid from the air.

Lime is acted on by light, neither does it combine with oxygen. Sulphur and phosphorus are the only simple combustibles with which it unites.

Sulphuret of lime may be formed by mixing its two component parts, reduced to a powder, and heating them in a crucible. They undergo a commencement of fusion, and form an acid taste. When it is exposed to the air, or moistened with water, its colour becoming greenish-yellow, sulphureted hydrogen is formed, and the sulphuret is converted into a hydrogenated sulphuret, which exhales a very fetid colour of sulphureted hydrogen gas. This hydrogenated sulphuret may be formed also by boiling a mixture of lime and sulphur in about ten times its weight of water, or by sprinkling quicklime with sulphur and then moistening it; the heat occasioned by the evaporation of the liquid is sufficient to form the compound. When this hydrogenated sulphuret is exposed to the air, it solubilizes oxygen; which combines at first with the hydrogen, and afterwards with the sulphur, and converts the compound into sulphate of lime.

Phosphuret of lime may be formed by the following process: put into the bottom of a glass tube, close at one end, one part of phosphorus; and, holding the tube horizontally, introduce five parts of lime in small lumps, so that they shall be about two inches above the phosphorus. Then place the tube horizontally among burning coal, so that the part of it which contains the lime may be made red hot, while the bottom of the tube containing the phosphorus remains cold.

When the lime becomes red-hot, raise the tube, and draw it along the coal till that part of it which contains the phosphorus is exposed to a red heat. The phosphorus is immediately volatilized, and passing through the hot lime combines with it. During the combustion a little becomes a glowing red heat, and a quantity of phosphureted hydrogen gas is emitted, which takes fire when it comes into the air. Lime does not combine with azote; but when combined with water, it unites readily with muriatic acid, and forms muriat of lime. It facilitates the oxidization of several of the metals, and it combines with several of the metallic oxides, and forms salts which have not hitherto been examined, if we except the compounds which it forms with the oxides of mercury and lead, which have been described by Berthollet.

The red oxide of mercury, boiled with lime-water, is partly dissolved, and the solution yields by evaporation on small transparent yellow crystals. This crimson has been called by some mercuriat of lime.

Lime-water also dissolves the red oxide of lead, and (still better) litharge. This solution, evaporated in a retort, gives very small transparent crystals, forming prismatic colours, and not more soluble in water than lime is. It is decomposed by all the alkaline sulphates, and by sulphureted hydrogen gas. The sulphure and muriatic acids precipitate the lead. This compound blackens wool, the nails, the white of eggs; but it does not affect the colour of silk; and, in the yeek of egg, nor animal oil. It is the lead which is precipitated upon these coloured substances in the state of oxide; for all acids can dissolve the mixture of lime and oxide of lead blackens these substances; a proof that the salt is easily formed.

Lime does not combine with alkalies. The affinities of lime are arranged by Bergman in the following order:

| Oxalic acid | Arsenic | Lactic | Citric |
| Phosphoric | Sulphurous | Acetic |
| Succinic | Sulphuric | Bitartric |
| Phosphorous | Sulphuric | Tartric |
| Tartaric | Succinic | Oxalic |
| Sulfurous | Nitric | Tartric |
| Chloric | Sulphuric | Tartric |
| Hydrochloric | Sulphuric | Tartric |

One of the most important uses of lime is in the formation of mortar as a cementing building. Mortar is composed of quicklime and sand reduced to a paste with water. When dry it becomes as hard as stone, and as durable; and adhering very strongly to the surfaces of the stones which it is employed to cement, the whole wall becomes in fact nothing else than one single stone. But this effect is produced very imperfectly unless the mortar is very well prepared.

The lime ought to be pure, completely free from carbonic acid, and in the state of a very fine powder: the sand should be free from clay, and partly in the state of fine sand, partly in that of gravel: the water should be pure; and if previously saturated with lime, so much the better. The best proportions, according to the experiments of Dr. Higgins, are three parts of fine sand, four parts of coarse sand, one part of quicklime recently slackened, and as little water as possible.

The stone consistence in which mortar acquires, is owing partly to the absorption of carbonic acid, but principally to the combination of part of the water with the lime. This last circumstance is the reason that if to common mortar one-fourth part of lime, reduced to powder without being slackened, is added, the mortar, when dry, acquires much greater solidity than if otherwise would do. This was first proposed by Lo.-riot; and a number of experiments were afterwards made by Morvean. The proportion by which this last advantage is to be obtained is left to answer best the following:

| Fine sand | .0 .3 |
| Cement of well-baked bricks | .6 |
| Slacked lime | .2 |
| Unslacked lime | .2 |

The same advantages may be attained by using as little water as possible in slackening the lime.

Higgins found that the addition of burnt bones improved mortar by giving it tenacity, and rendering it less apt to crack in drying; but they ought never to exceed one-thousandth of the lime employed.

When a little manganese is added to mortar, it acquires the important property of preventing under water, so much may be employed in constructing those edifices which are constantly exposed to the action of water. Lime-stone is often combined with manganese; in that case it becomes brown, a colour called manganese-stone.

**LIMESTONE.** See Salts, cements, limestone, primitive and secondary. See Rocks.

**LIMEUM, a genus of the class and order prostrate, including the asty rents.** The cat is five, long, equal, caps. globular, two-celled. There are three species, herbaceous plants of the Cape.

**LIMET, in a restricted sense, is used by mathematicians for a determinate quantity to which a variable one continually approaches; in which sense the circle may be said to be the limit of its circumscribed and inscribed polygons. In algebra, the term limit is applied to two quantities, one of which is greater, and the other less, than another quantity; and in this sense it is used in speaking of the limits of equations, whereby their solution is much facilitated.

The equation, $a + bx + cy + dz = 0$ is proposed; and transform it into the following equation:

$$y + 2ax + 3ay + 4z = 0$$

where the values of $y$ are less than the respective values of $x$, by the difference $c$. If you suppose $c$ to be taken such as to make all the co-efficients of the equation $y$ positive, viz.

$$c = \frac{a - b}{c - d}$$

then there being no variation of the signs in the equation, all the values of $y$ must be negative, and consequently the quantity $b$, by the values of $x$ are diminished, must be greater than the greatest positive value of $y$. And, conversing under water $z$, must be the limit of the root of the equation $a + bx + cy + dz = 0$.

It is sufficient, therefore, in order to find the limit, to employ the quantity substituted for $x$, in each of these expressions $a + bx + cy + dz = 0$, $a + bx + cy + dz = 0$, $a + bx + cy + dz = 0$, $a + bx + cy + dz = 0$, $a + bx + cy + dz = 0$, $a + bx + cy + dz = 0$, $a + bx + cy + dz = 0$.

Having found the limit that surpasses the greatest positive root, call it $m$. And if you assume $y = m - x$, and for $a$ substitute $m - y$,
the equation that will arise will have all its roots positive; because w is supposed to surpass all the values of x, its roots affirmative; for, if x were greater than any negative value of w, it follows that w + w must be positive.

What is here said of the above cubic equation, may be easily applied to others; and of all such equations, two limits are easily discovered, viz. the quadratic, which is less than the least, and the cube, found as above, which runs to the greatest; but none of the equations, but the quadratic, give the roots of the equation. But besides these, other limits may be added to the roots, which may be found by the method of which, the reader may consult Maclaurin's Algebra.

LIMITATION, a certain time prescribed by statute, within which an action must be brought. The time of limitation is twofold; first in writs, by divers acts of parliament; secondly to make a title to any inheritance, and that is by the common law.

Limitation on penal statutes. —All actions, suits, bills, indictments, or informations, which shall be brought for any forfeiture upon any penal statute, made or to be made, whereby the forfeiture shall be paid to the crown, her heirs or successors, or shall be within two years after the offence committed, and not after two years; and all actions, suits, bills, or informations, which shall be brought for any forfeiture upon any penal statute, made or to be made, except the statutes of tithes, the benefit of which is to be saved, and which are to be saved, and which is to be saved, the prosecution must be within that time. 31 Eliz. c. 5.

Limitation in regard to personal actions of assault and battery, actions arising upon contract and trespass.

All actions of trespass, of assault, battery, wounding, imprisonment, or any of them, shall be commenced and sued within four years next after the cause of such actions or suits, and not after. 21 Jac. I. c. 16.

Actions of account, &c. —All actions of trespass quare clausum fremit, all actions of trespass, detinue, trover, and replevin, all actions of account, and upon the case (other than such accounts as concern the trade of merchant, between merchant and merchant, all actions of debt grounded upon any lading, or contract without specialty, that is, not being by deed or under seal) all actions of debt for arrears of rent, and all actions of assault, battery, wounding, and imprisonment, shall be commenced within the time and limitation as followeth, and not after; that is to say, the said actions upon the case (other than for slander), and the said actions for trespass, debt, detinue, and replevin, and the said actions for trespass quare clausum fremit, within six years after the cause of such action. 21 Jac. c. 16.

Exception in relation to infants. —It has been held, that if an infant during his infancy, by his guardian bring an action, the defendant cannot plead the statute of limitation, although the cause of action accrued six years before; and the words of the statute are, that after his coming of age, &c.

Exception in relation to merchants' accounts. —As to this exception, it has been matter of much controversy, whether it extends to all actions and accounts relating to merchants and merciaclers, or to actions of account open and current only. But it is now settled, that accounts open and current only are within the statute; and that therefore, if an account be stated and settled between merchant and merchant, and a sum certain agreed to be due to one of them, if in such case, he to whom the money is due, do not bring his action within the limited time, he is barred by the statute. 2 Mod. 312.

The receiver or administrator. —If a receiver money belonging to a person who afterwards died intestate, and to whom it takes out administration, and brings an action against him, which the plaintiff pleads the statute of limitations, and the plaintiff replies, and shows that administration was committed to him such a year, which was within six years; though six years are expired since the receipt of the money, yet not being so since the administration committed, the action is not barred by the statute.

Where a debt barred by the statute shall be revived. —Any acknowledgment of the existence of the debt, however slight, will take it out of the statute, and the limitation will then run from that time; and where an acknowledgment is ambiguous, it shall be left to the consideration of the jury, whether it amounts or not to such acknowledgment. 2 Durn. & East, 760.

It is clearly agreed, that if after the six years, the debtor acknowledges the debt, and promise payment, that this revives it, and brings it out of the statute: as if a debtor by promissory note, or simple contract, promises within six years of the action brought, that he will pay the debt; though this was barred by statute, and not revolved by the statute, for as the note itself was at first but an evidence of the debt, so that being barred the acknowledgment of the debt is a new evidence of the debt, and being proved, will maintain an action for recovery. 1 Salk. 28.

Limits of a planet, its greatest excursion from the ecliptic, or which is the same thing, the points of its greatest latitude by the plane of its orbit. 1 Salk. 28.

LIMITED PROBLEM, a problem that admits of one solution, as to make a circle pass through three given points, not lying in the same right line.
LINES on the plain scale, are the line of clari, line of vases, line of tangents, line of secants, line of semitangents, line of leages; the construction and application of which see under the words SCALE, SAILING, INSTRUMENTS, &c.

LINES on Gunter's scale. See Gun-

ten's SCALE.

LINES of the sector. See INSTRU-
MENTS.

LINES, in fortification, are those of ap-
pellant, capital, defense, circumvallation, contravallation of the base, &c.

To LINES a work, signifies to strengthen a rampart with a firm wall; or to encompass a parapet or most with good turf, &c.

LINES, in the art of war, is understood of the disposition of an army, ranged in order of battle, with the front extended as far as may be, that it may not be flanked.

LINES, is also understood of the disposition of a fleet on the day of engage-
ment.

Ship of the LINES, a vessel large enough to be drawn up in the line, and to have a place in the parallel sea-sight.

LINE, also denotes a French measure containing the twelfth part of an inch, or the hundred and forty-fourth part of a foot. Geometers conceive the line subdivided into infinitesimal. The French line answers to the English barleycorn.

LINEAR Numbers, in mathematics, such as have relation to length only; such is a number which represents one side of a plane figure. If the plane figure be a square, the linear number is called a root.

LINEAR PROBLEM, that which may be solved geometrically, by the intersection of two linear lines. This is called a simple problem, and is capable of a solution.

LINEN, in commerce, a well-known kind of cloth, chiefly made of flax. See LINUM, and WEAV.

LINE. SEE GADUS.

LINIMENT. See PHARMACY.

LINNAEUS, a genus of the class and order idiananica angiosperma. The cal is double; the cor. bell-shaped; the berry dry, three-
seeded. There is one species, a herb of Sweden.

LINNET. See FRINGILL.

LINSEED. The seed of the plant linum.

LINUM.

LINSPINS, in the military art, small pins of iron, which keep the wheel of a caisson or wagon on the axle-tree; for when the end of the axle-tree is put through he nave, the lenspin is put in, to keep the wheel from falling off.

LINT, the scrapings of linen: which is used in dressing wands, and is made up in various forms, as tents, dofts, pledgets, &c. See SURGERY.

LINUM, flax: a genus of the pentagynia order, in the pantehria class of plants; and in the natural method ranking under the 4th order, genus. The calyx is unsegmented; the petals are five; the capsule is quinquavalved and decumoloculare; and the seeds are solitary. There are 32 species, of which the most remarkable are

1. The ustilaginum, or common manunit flax.

2. The paremo, or perennial Siberian flax, with umbelate clusters of large blue flowers.

3. The cathart cum, or purging flax, a very small plant, not above four or five inches high: found wild upon chalky hills near in dry pleasure-gardens.

The first species is cultivated on the fields for the use of the manufacturers. The sec-

ond sort is chiefly ornamental. The vir-

tue of the third species is expressed in its title: its growth in water or wine of a handful of the seed (than) or a dram of them in substance when dried, is said to purge without inconvenience.

Of the cultivation of flax. A skilful flax-

 raiser always sows free, open, deep loam; and all grounds that produced the preceding year a good crop of turnips, cabbages, potatoes, barley, or broad clover; or have been formerly laid down rich, and kept for some time, are fit for the cultivation of flax. If the lines be sown early, and the flax not allowed to stand for a crop, a crop of tur-

nips may be got after the flax that very year; the second year a crop of rye or barley may be taken; and third year, grass-

seeds are sometimes sown along with the lineseed. Of preceding crops, potatoes and hemp are the best preparation for flax, if the ground is free and open, it should be turned in the autumn; if more moist as in clay or shallow, as it is not so salable, not deeper than two and a half inches. It should be laid flat, reduced to a fine gar-

den mould by good harrowing, and all stumps and stones should be carried off. Ex-

cept a little pegging for cold or sour ground, no other dung should be used pre-

paratory for flax, because it produces too many weeds, and throws up the flax thin and poor. Before sowing, the bulky clods should be broken, or carried up the ground; and stones, quickenings, and every other thing that may hinder the growth of the flax, should be carefully taken away. If the brighter in colour, and heavier the seed is, so much the better; that which when bruised appears of a light or yellowish green, and fresher in the heart, oily, and not dry, and smells and tastes sweet, and not harsh, is the best seed. Of the preceding year's growth, for the most part, answers best; but it seldom succeeds if kept another year. It ripens sooner than most other flax seed. Phialadelphia seed produces fine lint and a good size of the bolls, because it is sown thick, and answers best in wet cold soils.

The quantity of lineseed sown should be proportioned to the condition of the soil; for if the ground is in good heart, and the seed sown thick, the crop will be in danger of falling before it is ready for pulling. The time for sowing lineseed is from the middle of March to the end of April, as the ground and season answer; but the earlier the seed is sown, the less the crop interferes with the corn harvest. Late-sown lineseed may grow long, but the flax upon the stalk will be thin and puny.

Flax ought to be weeded, when the crop is about four inches long. In longer defer-

red, the weeds will also much break and bend the stalks, and will perhaps never recover their natural strength; and when the flax grows crooked, it is more liable to be hurt in the rippling and swaying. Quick-

cut grass should be taken up; for, being strongly rooted, the flax of it always ceases a great deal of the flax. If there is an appearance of a settled drought, it is bet-
ter to defer the weeding, than by that opera-
tion to expose the tender root of the flax to the drought.

In watering, a running stream wastes the flax, makes it white, and frequently carries off the raip of the flax; the quantity and motion of the water, also waste and whiten the flax, though not so much as running streams. Both rivers and lochs water the flax quicker than canals. The greater way the river or brook has run, the softer, and therefore the better, will the water be.

Springs, or short runs from hills, are too cold,
unless the water is allowed to stand long in the canal. Water from coal or iron is very bad for flax. A little of the powder of galls thrown into a glass of water will discover if it comes from minerals of that kind, by turning it into a dark colour, more or less tinge in proportion to the quantity of metal it contains. When the water is brought to a proper heat, small plants will be rising quickly in it, numbers of small insects and reptiles will be generating there, and bubbles of air rising up. If two flax plants are then held very tender, it must be gently handled. The thinner it is spread the better, as it is then more equally exposed to the weather. But it ought never to be spread during a heavy shower, as the ground will be washed and the harle too much, which is then excessively tender, but soon after becomes firm enough to bear the rains, which, with the open air and sunshine, cleans, softens, and purifies the harle to the degree wanted, and makes it blister from the boon. In short, after the flax has got a little firmness by being a few hours spread in dry weather, the more rain and sunshine it gets the better. If there is little danger of high winds carrying off the flax, it will be much the better for being turned about once a week. If it is not to be turned, it ought to be very thin spread. The spreading of flax and hemp, which requires a round hand, is a great deal of labor. The flax-riser should spread his first row of flax at the end of the field opposite to the point whence the most violent wind commonly comes, and ride over the crops foremost. He makes the root ends of every other row overlap the crop ends of the former row three or four inches, and binds down the last row with a rope, by which means the wind does not easily get below the lint to blow it away; and as the crop ends are seldom so fully watered as the root ends, the overlapping has an effect like giving the crop ends more watering.

A dry day ought to be chosen for taking up the flax; and if there is no appearance of high wind, it should be loosened from the heath or grass, and left loose for some hours, to make it thoroughly dry.

As a great quantity of flax can scarcely be wholly watered and grased, and as the different qualities will be better separated at lifting the flax off the grass; therefore at that time each different kind should be gathered together, and kept by itself; that is, all of the same colour, length, and grade.

The smaller the heath lint is made up in, the better for drying, and the more convenient for stacking, housing, &c., and in making up these heaths, as in every other operation upon flax, it is of great consequence that the lint be laid together as it grew, the root ends together, and the crop ends together. The profit on five acres of flax raised in Shropshire was 40s. 4d. 5d.

LION. See Felis.

LIPARIA, a genus of the diadymbia gynaecous class and order. The calv. is five-lobed; cor. wings two lobed, below; stam., the larger, with three shorter teeth; legume ovate. There are four species, shrubs of the Cape.

LIPPIA, a genus of the din]%numia gynoecous class and order. The calv. is four-toothed; the caps. one-celled, three-valved, two-seeded; seed one, two-celled. There are five species, shrubs of America.

LIQUAMBAR. See Sweet gum tree, a genus of the polyandria order, in the monogyna class of plants, commonly called Liquidambar: it is a deciduous tree, native of the rich moist parts of Virginia and Mexico. It will shoot in a regular manner to thirty or forty feet high, having its young twigs covered with a smooth light-brown bark, while those of the older are of a darker colour. The flowers are of a kind of saffron-colour; they are produced at the ends of the branches in May, and sometimes sooner; and are succeeded by large round brown fruit, which looks singular, but is thought by many to be no ornament to the tree. 2. The peregrinus, Canad. liquidambar, or spleenwort, is a native of the United States. The young branches of this species are slender, tough, and hardy. The flowers come out from the sides of the branches, like the former; and they are succeeded by small round pods which seldom ripen in England. These may be propagated either by seeds or layers.

The leaves of this tree emit their odoriferous particles in such plenty as to perfume the air—sometimes for many miles. The tree itself excites such a fragrant transparent resin, as to have given occasion to its being taken for the sweet storax. (See Styx.) These trees, therefore, are very proper to be planted singly in large grounds, that they may amply display their fine pyramidal growth, or to be set in places near seats, pavilions, &c. The resin was formerly of great use as a perfume, and is at present no stranger in the shops.

LIQUORICE. See Glycyrrhiza, and Materia Medica.

LIRODENDRON, the Tulip-tree, a genus of the polyandria order, in the monogyna class of plants; and in the natural method ranking under the 3rd order, caudatae. The calyx is triphyllous; there are nine petals; and the seeds are embittered in such a manner as to form a cone. There are two species; the tulipera, is best known here, and is a deciduous tree, native of most part of America. It rises with a large upright trunk, branching forty or fifty feet high. The trunk, which often attains to a circumference of thirty feet high, is covered with a grey bark. The leaves grow irregularly, and the branches from long quadrilateral. They are of a particular structure, being composed of three lobes, the middlemost of which is shortened in such a manner that it appears as if it had been cut off and hollowed out at the middle, and the sides rounded off. They are about four or five inches long, and as many broad. The flowers are produced with us in July, at the ends of the branches. The number of petals of which each is composed, like those of the tulip, is six; and these are spotted with green, red, white, and yellow. The flowers
are succeeded by large cones, which never ripen in England.

LIPHYTA, a genus of the pentandria monogynia class and order. The cal.

LITTHARUM, a genus of the diandria monogynia class and order. The cal.

LITHOPHYLUM, the name of Linnæus's third order of vegetables.

LITUS, a genus of the monogynia order, in the pentadria class; of plant.

LITHOSTRÆTUM, a genus of the Linnæus's third order of vegetables.

LITHOSPERMUM, a genus of the monogynia order, in the pentandria class; of plant.

LITHOZAMIAS, a genus of the Diandria monogynia class and order. The female cal.

LIVELIY. See Anatomy.

LIVELY of seisin, in law, signifies delivering the possession of lands, &c. to him who has a right to them. There are two kinds of lively and seisin; lively in law, which implies the deliverer being in view of the land, house, &c., or other thing granted, says to the feoffor, on delivery of the deed, "I give to you the house, &c., and to hold you and to your heirs, so go into the possession of the property accordingly." And lively in deed, is where the parties or the attorneys by them authorised, coming to the door of the house, or upon some part of the land, declare the occasion of their meeting before witnesses, read the deed, or its contents, and in case it be made by attorney, the letter of attorney is also read, after which, if the delivery is of a house, the grantor, or his attorney, takes the ring, key, or latch belonging to the door, or if it be a land, a turf, or clad of earth, and a twig of one of the trees, and delivering them with the deed to the grantee or his attorney, says, I A.B. deliver to you possession, and seisin of this message or tenement, &c. to hold to you, your heirs and assigns, according to the purport, true intent, and meaning of this indenture, or deed of feoff.

Loved; for a lease and release, a bargain and sale by deed intituled, are sufficient to vest the grantees with possession, without the formality of lively.

LIVYMEN OF LONDON, are a number of men selected from among the freemen of each company. Out of this body, the common council, sheriff, and other superior officers for the government of the city are elected, and among themselves the privilege of giving their votes for members of parliament, from which the rest of the citizens are excluded.

LIVES, or insurance of Lives. See Insurance.

LIXUUM. See LEXURN.

LIZARD. See Lacerta.

LOAD, or Lodge, in mining, a word used especially in the tin-mines, for any regular vein or course of their primary positions, which must commonly load means a metallic vein. It is to be observed, that mines in general are veins within the earth, whose sides receding from or approaching to each other, make them of unequal breadth in different places, sometimes forming large spaces, which are called holes; these holes are filled like the rest with substances, which, whether metallic, or of any other nature, are called lodes. These lodes, if the forming loads are reducible to metal, the loads are by the English miners said to be alive, otherwise they are termed dead loads.

The difference between death and life is then attempted by the crossing of a vein of earth or stone, or some other metalline substance; in which case it generally happens, that one part of the load is moved to a considerable distance on one side. A miner considers himself as a funeral corps, a flogging, and the part of the load which is moved, is by them said to be heaved. This fracture or heave of a load, according to Mr. Price, is produced by a subsidence or elevation of the strata from their primary situations, which he supposes to have been so horizontal or parallel to the surface of the earth, and therefore should more properly be called a depression than a heave. This subsidence or heave was produced by a necessary load to the miner, did not experience teach him that as the loads always run on the sides of the hills, so the part heaved is always moved toward the descent of the hill so that the miner's looking toward the ascent of the hill, and meeting a flogging, considers himself as working in the heaved part; whereas, cutting through the flogging, he works upon its back up the ascent of the hill, till he recovers the load, and vice versa.

LOAMS. See Husbandry.

LOANS, in political economy, sums of money, generally of large amount, borrowed from individuals or public bodies, for the service of the state. They are either compulsory, in which case they may be more properly termed requisitions; or voluntary, which is the only mode that can be frequently resorted to with advantage. Loans are sometimes furnished by public companies as a consideration for peculiar privileges secured to them; but are much more commonly advanced by individuals on a certain interest being allowed for the use of the money, either for a term of years, or until the principal shall be repaid.

The practice of borrowing money, for defraying part of the extraordinary expenses in time of war, had been adopted in other countries long before it was introduced into Great Britain; but it has been carried to a far greater extent here than by any other state in the world. From which the government has been enabled to raise the largest sums, has arisen entirely from the strict punctuality with which it has constantly made good all pecuniary engagements.

LUCULLUS, a name given to an officer who usually conducts negotiations of this kind on the part of the government, and the agreement is afterward confirmed by parliament; the governor and company of the bank of England, having of late years been usually appointed receivers of the contributions, for which they have an allowance, at a certain rate per million; and the sums received by them are paid into the exchequer, with a fair prospect of profit, and the cost.

The money appropriated to the payment of interest or annuities, is issued at the receipt of the exchequer to the chief cashier of the bank upon account, and he is enjoined to pay the same to the several subscribers in their due course. The bank detain their allowance for receiving the contributions out of the sums received, and likewise what they have allowed as dividends to their subscribers, till they receive the money before the times fixed for the several instalments.

When the parliament has voted the supplies, and the extent of the loan found necessary, the communication is usually made to the bank or stock exchange stating the particular stock on which the loan is to be made, and fixing a day for those who intend to bid for it to wait on the minor and艾维斯 of the bank, in the mean time each person forms his list of friends who are to take different proportions with him in case he succeeds. When the day comes, each party offers as low as he thinks he can venture to, with a fair prospect of profit, and the lowest offer is generally accepted. The only step to be taken by those who are not of the number just mentioned, and who may wish to take a share in the transaction, is to pay a subscription for a part of his subscription, which at first may sometimes be had without any premium, or for a very small one, for it cannot be presumed that each person, who have subscribed the whole sum to be raised, indeed, or can keep it, but that they propose to include in their subscriptions a great number of their connections and acquaintance. Sometimes the subscription lies open to the public to the bank, as in the instance of the loan of eighteen millions for the service of the year 1797, and then every person is at liberty to subscribe what he thinks proper, and if upon casting up the whole, there is a surplus subscribed, which has generally been the case, the sum each person has subscribed, is reduced in an equal proportion, so as to make in the whole the sum fixed by parliament. As soon as conveniently may be, after the subscription is closed, receipts are made out, and delivered to the subscribers, for the several sums by them subscribed; and for the convenience of sale, every subscriber of a considerable sum has sundry receipts for different proportions of his whole sum, by which means he can readily part with what sum he wishes proper to transfer; and in this way the assignment is drawn upon the back of the receipt, which being signed and witnessed, transfers the
LOANS.

From the difference in the terms of the loan, with respect to the capital created, the rate of interest it bears, and the different periods of the terminable annuities which have been granted with most of the loans, it is evident, that in order to form a proper comparison of the interest paid for the money borrowed at different periods, various conditions must be brought into some degree of uniformity; and the most obvious mode of doing this is, by converting that part of the terminable annuities into equivalent perpetual annuities; that is, into the additional interest, which must have been paid in lieu of such terminable annuities.

The rate of interest at which such conversion is made affects the result in some instances very materially; thus, the perpetual annuity, which is equal to an annuity of 10l. for 21 years, is at 3 per cent. 4l. 12s. 6d. but at 5 per cent. 4l. 16s. 3d.; and the perpetual annuity equal to an annuity of 10l. for 60 years, which at 3 per cent. is 8l. 6s. is at 5 per cent. 9l. 9s. 3d. from which it is evident, that, if the term of the annuities, granted during different periods, are all valued at the same rate of interest, the comparison will by no means be just; for if a high rate is adopted, the loans which have been obtained at the lowest interest will be set in an unfavourable light; and if, on the contrary, they are all valued at a low rate, the charge of those loans, for which the highest interest is paid, will appear less than really is. Nor is an average rate more proper for exhibiting the real difference in the terms on which the several loans have been obtained. The least objectionable mode appears to be to convert the rate of interest into perpetual annuities, according to the current rate of interest at the time when the annuities were granted, as it is upon the rate of interest that the proportionate value of an annuity for a certain term to the perpetuity depends; and in forming the following statements, the conversion has been made at the interest produced by money invested in the three per cents. according to the price of this stock at the times when the respective loans were settled: for, though by this means, the rate is, in each case, rather lower than it would have been had the interest produced by 4 or 5 per cent. stock been adopted, it is most probable, from the nature of the principal loans, that the stock which must have been given in lieu of a long annuity, would chiefly have been three per cents.; and, therefore, the interest equivalent to the long annuity should be found according to the interest produced by this stock.

It may also be proper to remark, that, as the terminable annuities have mostly been granted for a small part of the whole interest, particularly on the loans of the last war, the difference of a quarter or even half per cent., in the rate at which they are valued has in general but little effect on the whole rate per cent. of the loan. Thus, if the long annuity of the loan of 14,500,000l., in 1797, is valued at 6 per cent. (being the interest produced by 3 per cent. at that time) it makes the whole rate per cent. 6l. 6s. 10d.; but, if the long annuity is valued at 5½ per cent. it will be 6l. 6s. 9½d.; at 5½ per cent.

Thus, the interest paid, however, focuses the real burden of each loan to the country, and is the circumstance to be chiefly attended to in all comparisons of the whole present advantage or disadvantage of the terms on which the public debts have been contracted at different periods.

During the reign of Queen Anne, loans were chiefly raised on annuities for 99 years, till 1711, when, by the establishment of the South Sea company, a variety of debts were consolidated and made a permanent capital, bearing 6 per cent. interest. About this period lotteries were also frequently adopted for raising money for the public service, under which form a considerable premium was given, in addition to a high rate of interest. This mode of raising money was followed in 1712, 1713, and 1714. In the latter year, though the interest paid was equal to only 5l. 7s. 2d. per cent. on the sum borrowed, the premium allowed was upwards of 34l. per cent.; but as peace was restored, and the legal rate of interest had been reduced to 5 per cent., it seemed that a larger premium was allowed, for the sake of appearing to borrow at a moderate rate of interest.

In the reign of George I., the interest on a considerable part of the public debts was reduced to 5 per cent. and the few loans that were raised at a small amount: that of the year 1720 was obtained at little more than 4 per cent. interest.
About 1730 the current rate of interest was 5 per cent.; and in 1736, government was limited to 9 per cent. per annum. The extraordinary sums necessary for defraying the expenses of the war which began in 1739, were at first obtained from the sinking fund and the lottery; a payment from the bank, in 1742, rendered by only a small loan necessary in that year, which was obtained at little more than 3 per cent. interest. In the succeeding years the following sums were raised by loan:

Loans of the seven years war.

1737 - 2,000,000 - 3 12 0
1738 - 3,000,000 - 3 14 3
1739 - 5,000,000 - 3 6 0
1740 - 6,000,000 - 3 10 9
1741 - 8,000,000 - 3 13 7
1742 - 12,000,000 - 4 10 9
1743 - 12,000,000 - 4 10 9
1744 - 3,000,000 - 4 4 2

Loans of the American war.

1776 - 2,000,000 - 3 9 8
1777 - 5,000,000 - 4 5 2
1778 - 6,000,000 - 4 18 7
1779 - 7,000,000 - 5 18 10
1780 - 12,000,000 - 5 18 10
1781 - 12,000,000 - 5 11 1
1782 - 13,500,000 - 5 18 1
1783 - 12,000,000 - 4 13 9
1784 - 6,000,000 - 5 6 1

Loans of the war with the French republic.

1793 - 4,500,000 - 4 3 4
1794 - 11,000,000 - 4 10 7
1795 - 18,000,000 - 4 15 8
1796 - 18,000,000 - 4 14 9
1797 - 7,500,000 - 4 12 2
1798 - 15,000,000 - 5 14 1
1799 - 18,000,000 - 5 6 1
1800 - 17,000,000 - 6 4 0
1801 - 3,000,000 - 5 12 5
1802 - 15,500,000 - 5 5 0
1803 - 20,500,000 - 4 14 2
1804 - 28,000,000 - 5 5 5

Loans of the war with the French empire.

1803 - 12,000,000 - 5 2
1804 - 14,500,000 - 5 9 2
1805 - 22,500,000 - 5 3 2
1806 - 20,000,000 - 4 10 7

LOASA, a genus of the polyandria monogynia class and order. The caly is five-leafed; cor. five-petalled; nect. five-leaved; caps. four-foliaged, one-celled, three-celled, many-seeded. There is one species, an animal of South America.

LOBE. See Anatomy.

LOBELIA, cardinal-flower, a genus of the monogynia order, in the syngnesia class of plants, and in the natural method ranking under the 9th order, campanaceae. The calyx is quinquenatus; the corolla monopetalous and irregular; the capsule inferior, bilocular or unilocular; there are five petals in the corolla, but only four of them are cultivated in our gardens, two of which are hardy herba- ceous plants for the open ground, and two

shrubby plants for the shade. They are all fibrous-rooted perennials, rising with erect stems of two to six feet high, ornamented with oblong, oval, spear-simped, simple leaves, and spikes of beautiful monopetalous, somewhat tinged, five-petalled flowers, of scarlet, blue, and violet colours, and numerous aborted fruits, and cuttings of their stalks. The tender kind require the common treatment of other exotics. They are natives of America, from which they are introduced in England.

The root of the species called the sphyllumata (see Plate Nat. Hist. fig. 292) is an article of the materia medica. This species grows in most places in Virginia, and bears our winters. It is perennial, has an erect stalk three or four feet high, blue flowers, a milky juice, and a rank smell. The root consists of white fibres about two inches long, resembles tobacco in taste, which remains on the tongue, and is apt to excite vomiting. It is used by the North American Indians as a specific in the venereal disease. The benefit, however, to be derived from this article has not, as far as we know, been confirmed either in Britain or by the other nations who have made admission of this herb, likewise to other instruments. The office, therefore, which in other locks is performed by the extreme point of the key, is here accomplished by a lever, which, when it approaches the bolt till every part of the lock has undergone a change of position. The necessity of this change to the purposes of the lock, and the absolute impossibility of effecting it otherwise, without the proper key, are the points to be ascertained.

Plate Lock and Loom, fig. 4, represents a mortice lock, made under the patent which Mr. Stansbury took out in 1805, for various purposes, and which is the springleatch, as in common; the end B of this is bent, and has a frame D screwed to it, carrying a roller E; against this roller a wedge F called a pusher, shown separately in fig. 5, acts, the spindle G on which this pusher is fixed, slides through holes in the side-plate of the lock, so as to have no shake, and on each end is fastened a handle; by this arrangement it is plain that the handle of the wedge is pushed from without the door, its wedge E will act against the roller E, fig. 4, draw back the bolt A, and release the door; a continuation of the same motion opens it. The operations from within the room are the same, except that the handle of the pusher must be pulled instead of pushed; but as it is on the other end of the spindle, the operation on the wedge and bolt is the same.

For the convenience of persons not acquainted with the new method, the bolt may be drawn back by turning the handle, as in the common lock, ii is a piece of metal, figs. 4 and 5, which has a round collar a above, and to this is applied b, which work in holes in the side-plates of the lock, so as to turn easily round; this piece has a hole through it, large enough to admit the pusher to move up and down, and having in one side thereof admits the wedge F; so that when the spindle is turned round, one of the two arms d of this piece, acts against the arm b of the bolt A, fig. 4, and draws back the bolt at the same time, in the common way. In order to reduce the friction against the bolt, in shutting the door, a small roller e, fig. 1, is applied to it. In lieu of the slip-
If this sheet is cut out, the second order of the conic sections, viz., either the parabola, the circle, ellipse, or hyperbola: if an equation, therefore, is given, whose locus is of the second degree, and it is required to draw the conic section which is the locus thereof, first draw a parabola, ellipse, or hyperbola, so as that the equation expressing the nature thereof may be as compound as possible, in order to get general equations or formulas, by examining the peculiar properties whereof we may know which of these formulas the given equation ought to have regard to; that is, which of the conic sections will be the locus of the proposed equation. This known, compare all the terms of the proposed equation with the terms of the general formula of that conic section, which you have found will be the locus of the given equation; by which means you will find which section is the equation given.

An equation, whose locus is a conic section, is given, and the particular section whereof it is the locus is required; all the preceding terms of this section being brought over to one side, so that the other is equal to nothing, there will be two cases.

Case I. When the rectangle \(xy\) is not in the given equation. 1. If either \(y\) or \(x\) is in the same equation, the locus will be a parabola, ellipse, or hyperbola, in the equation with the sign, the lines will be an ellipse or a circle. 3. If \(x\) or \(y\) have different signs, the locus will be an hyperbola, or a hyperbola opposite sections regarding their diameters.

Case II. When the rectangle \(xy\) is in the given equation. 1. If neither of the squares \(x^2\) or \(y^2\) or their product one, is in the same, the locus of it will be an hyperbola between the asymptotes. 2. If \(y\) and \(x\) are therein, having different signs, the locus will be an hyperbola regarding its diameters. 3. If both the squares \(x^2\) and \(y^2\) are in the equation, you must free the square \(xy\) from fractions; and then the locus will be an hyperbola, when the square of \(x\) or \(y\) multiplying \(xy\), is equal to the fraction multiplying \(xy\); or an ellipse, or circle, when the same is less; and an hyperbola, or the opposite sections, regarding their diameters, when greater.

LOCUST. See Gryllus.

LOGBOARD, in military affairs, is a work raised with earth, gibbons, fascines, woolpacks, or matelots, to cover the besiegers from the enemy's fire, and to prevent their losing a place which they have gained, and are resolved, if possible, to keep. For this purpose, when a logboard is to be made on the glades, covered way, or in the breach, there must be great provision made of fascines, sand-bags, &c. in the trenches; and during the action, the pioneers with fascines, sand-bags, &c. should be making the logboards at their leisure, or at such a time and in an advantageous manner as possible from the opposite bastion, or the place most to be feared.

LOEINGIA, a genus of the class and order Tritoncea monogynia. The calyx is five-leaved; corolla five-petalled; capsule one-celled, three-valved. There is one species, an annual of Spain.

LOESELIA, a genus of the dicotyledonous angiospermous class of plants, the flower of which is monoeocious and unisexual at the limb; the fruit is a twilled capsule, with several angulated seeds in each cell. There is one species, a herb of South America.

LOG, in naval affairs, is a flat piece of wood, shaped somewhat like a drawer, with a piece of lead fastened to its bottom, which makes it stand or swim upright in the water. To this log is fastened a long line, called the log-line; and this is commonly divided into certain spaces, or log length, by knots, which are pieces of knotted twine inerced between the strands of the line; which, shew, by means of a half-minute glass, how many of these spaces or knots are run out in half a minute. They commonly begin to count at the distance of about 10 fathons or 60 feet from the log; so that the log, when it is hoven overboard, may be out of the eddy of the ship's wake before they begin to count; and for the ready discovery of this point of commencement, there is commonly fastened at it a red rag.

The log being thus prepared, and hoven overboard, the log-line, and the line veered out by the helm of a real, as the ship sails, will, shew how far the ship has run in a given time, and consequently her rate of sailing.

Hence it is evident, that as the distance of the knots bears the same proportion to a mile as half a minute does to an hour, whatever number of knots the ship runs in half a minute, the same number of miles she will run in an hour, supposing the ship to sail with the same degree of velocity during that time; and therefore, in order to know her rate of sailing, it is the general way to have the log every hour; but if the force or direction of the wind and weather, they do not continue the same during the whole hour, or if there has been more sail set, or any sail handed in, by which the ship has sailed faster or slower than she did at the time of having the log, there must then be an allowance made for it accordingly.

LOGBOARD, a table generally divided into five columns, in the first of which is entered the time of the day; in the second the course steered; in the third, the number of knots run on the reel each time of having the log; in the fourth, from what point the wind blows; and in the fifth, observations on the weather, variation of the compass, &c.

LOGBOOK, a book ruled in columns like the log-board, into which the account on the log-board is transcribed every day at noon; whence, after it is corrected, &c. it is entered into the journal. See LOG-JOURNAL.

LOGWOOD, in commerce. See HEMATOXYLUM.

Logwood is used by dyers for dying blacks and blues.

LOGARITHMIC, in general, something belonging to logarithms. See LOGARITHMS.

LOGARITHMIC CURVES, on the line AN (Plate Miscell., fig. 153) both ways indispensably extermated, and taken, AC, CF, EG, GI, HL, on the right hand, and AE, CE, &c. on the left, all equal to one another, and if at the points P, g, c, e, G, i, l, be erected to the right line AN, the perpendiculars PG, GA, CB, ED, EF, GI, IK,
L. M, which let be continually proportional, and represent numbers, viz. AB, 1; CD, 10; EF, 100, &c. shall we have two progressions of lines, arithmetical and geometrical: for the lines AC, AE, AG, &c. are in arithmetical progression, or, as 1, 2, 3, 4, 5, &c. and so represent the logarithms to which the geometrical lines AB, CD, EF, &c. do correspond. For since AC is triple of the right line AG, and the right line GH shall be in the third place from unity, if CD is in the first; so likewise shall LM be in the fifth place, since AL = 3 AC. If the extremities of the progression, D and E, are joined by the right lines, the figure SBNML will become a polygon, consisting of more or less sides, according as there are more or less terms in the progression.

In the parts AC, CE, EG, &c. are bisected in the points \( \xi, \eta, \zeta \), and there are again raised the perpendiculars \( cd, ef, gh, li, \) which are mean proportions between \( AB, CD \); \( CD, EF \), &c. then there will arise a new set of proportions, whose terms beginning from that which immediately follows unity, are double of those in the first series, and the difference of the terms is becomes less, and approaches nearer to a ratio of equality. For, following, in this new series, the right lines AL, AC, express the distances of the terms LM, cd, from unity, viz. since AL is ten times greater than AC, LM shall be the tenth term of the series from unity; and because this is three times greater than \( AC \), \( ef \) will be the third term of the series if \( cd \) is the first, and there shall be two mean proportions between \( AB \) and \( ef \); and between \( AB \) and \( LM \) there will be nine mean proportions. And if the extremities of the lines \( bd, df, ef \), &c. are joined by right lines, there will be a new polygon made consisting of more or shorter sides than the first.

If, in this manner, mean proportions are continually placed between every two terms, the number of terms at last will be made so great, as also the number of the sides of the polygon, as will be greater than any given number, or to be infinite; and every side of the polygon so lessened, as to become less than any given right line; and consequently the polygon will be changed into a curve-line, or into a curved-line figure, as is the case in the first case, it may be conceived as a polygon whose sides are infinitely small and infinite in number. A curve described after this manner, is called logarithmic.

It is manifest, from this description of the logarithmic curve, that all numbers at equal distances are continually proportional. It is also plain, that if there are four numbers, \( AB, CD, \) \( \xi, \eta \), \( M, L \), such that the distance between the first and second, is equal to the distance between the third and fourth, let the distance from the second to the third be what it will, these numbers will be proportional to the distances \( AC, CD, \xi M, L \), equal, \( AB \) shall be to the increment of \( \xi D \), as \( 1K \) is to the increment of \( 1T \). Wherefore, by composition, \( AB : CD : : 1K : M L \). And conversely, if four numbers are proportional, the distance between the first and second shall be equal to the distance between the third and fourth.

The distance between any two numbers, is called the logarithm of the ratio of those numbers; and, indeed, does not measure the ratio itself, but the number of terms in a given series of geometrical proportions, proceeding from one number to another, and defines the number of equal ratios by which the greater may be divided into, and shew, the products and quotients of the latter.

LOGARITHMS are numbers so contrived and adapted to other numbers, that the sums and differences of those numbers correspond to, and show, the products and quotients of the latter.

Or, more generally, logarithms are the numerical exponents of ratios; or a series of numbers in arithmetical progression, answering to another series of numbers in geometrical progression.

Thus,
\[ 0, 1, 2, 3, 4, 5; \text{Indices, or logarithms.} \]
\[ 1, 2, 3, 4, 5; \text{Ind. or log.} \]

Thus, if a fraction is required, the logarithm of its numerator will be found, and that of its denominator multiplied, and their sum will be the logarithm of the quotient.

Thus, the series 1, 2, 3, 4, 5, &c. is the geometrical progression applied to the calculation of numbers, and will, for all practical purposes, be sufficient, because the operations of addition are the most frequent in calculations, and the principle of resemblance is sufficient for finding the differences of such numbers, and for the computation of any other calculations required; and those numbers are easily found and applied, and are sufficient for all calculations, and are for that reason preferred to any other numbers for that purpose.

LOGARITHMS are more generally considered as numbers proportional to those of any other series in which the sum of the terms is, and the difference of the terms is, constant. And such an increasing series is continued by each term being added to the last term, and the last term increased by the original difference, until the number of terms is such as will answer the purpose. And thus the logarithms of the numbers 1, 2, 3, 4, &c. are numbers proportional to the numerical series of the same numbers, and such as will answer the same purpose for the calculation of numbers.
LOGARITHMS.

numbers such terms of that series as are nearest to them, and their indices for the logarithms. But then, to construct logarithms in this manner, to suit an exact number, and degree of exactness, as would be necessary to make them of any considerable use, is next to impossible, because of the almost infinite labour and time it would require. This, however, is an introduction for understanding the method of the noble inventor, who undoubtedly first took the hint of making logarithms from the consideration of the indices of a geometrical series; and by means of the principles and known properties of these progressions he first formed his tables, and advanced them to the practical purposes intended.

To find the logarithm of any of the natural numbers, 1, 2, 3, 4, 5, &c., according to the method of Napier. — Let the geometrical series, 1, 10, 100, 1000, &c. and apply to it the arithmetical series 1, 2, 3, 4, &c. as logarithms. 2. Find a geometric mean between 1 and 10, 10 and 100, or any other two adjacent terms of the series between which the number proposed lies. 3. Between the means, thus found, and the nearest extreme, find another geometric mean, in the same manner; and so on, till you are arrived within the proposed limit of the number whose logarithm is sought. 4. Find as many arithmetical means as you desire, by the same process as you found the geometric ones, and the last of these will be the logarithm answering to the number required.

Example. Let it be required to find the logarithm of 9.

Here the numbers between which 9 lies are 1 and 10.

First, then, the log. of 10 is 1, and the log. of 1 is 0, therefore \( \log \frac{10}{2} = 0.5 \) is the arithmetical mean, and \( \log (1 \times 10) = 1 \) is the geometric mean; whence the logarithm of 5 is obtained. Secondly, the log. of 10 is 1, and the log. of 5 is 0.777; therefore \( \log \frac{10}{5} = 0.75 \) is the arithmetical mean, and \( \log (10 \times 5) = 1.5777 \) is the geometric mean; whence the logarithm of 10 is obtained.

Thirdly, the log. of 10 is 1, and the log. of 5 is 0.777; therefore \( \log \frac{10}{5} = 0.75 \) is the arithmetical mean, and \( \log (10 \times 5) = 1.5777 \) is the geometric mean; whence the logarithm of 10 is obtained.

Fourthly, the log. of 10 is 1, and the log. of 5 is 0.777; therefore \( \log \frac{10}{5} = 0.75 \) is the arithmetical mean, and \( \log (10 \times 5) = 1.5777 \) is the geometric mean; whence the logarithm of 10 is obtained.

Fifthly, the log. of 10 is 1, and the log. of 5 is 0.777; therefore \( \log \frac{10}{5} = 0.75 \) is the arithmetical mean, and \( \log (10 \times 5) = 1.5777 \) is the geometric mean; whence the logarithm of 10 is obtained.

Sixthly, the log. of 10 is 1, and the log. of 5 is 0.777; therefore \( \log \frac{10}{5} = 0.75 \) is the arithmetical mean, and \( \log (10 \times 5) = 1.5777 \) is the geometric mean; whence the logarithm of 10 is obtained.

And, proceeding in this manner, after 25 extractions, the logarithm of 5 is obtained. This process may be continued till the logarithm of 9 is found, and it is sufficiently exact for all practical purposes.

Vol. II.
To reduce Powers by Logarithms.---Multiply the logarithm of the number given, by the index of the power required, the product will be the logarithm of the power sought.

Example. Let the cube of 22 be required by logarithms. The logarithm of 22 = 1.360150, which multiplied by 3, is 4.080450, the logarithm of 32768, the cube of 22. But in raising powers, viz. squaring, cubing, &c. of any decimal fraction by logarithms, it must be observed, that the first significant figure of the power be put so many places below the place of units, as the number of digits in the logarithm wants of 10, 100, &c. multiplied by the index of the power.

To extract the Roots of Powers by Logarithms.---Divide the logarithm of the number by the index of the power, the quotient is the logarithm of the root sought.

To find Means Proportional between any two numbers, find the logarithm of one, and subtract the logarithm of the other, from it, the number answering to the difference, is the mean proportional required.

Example. Let three mean proportional be sought, between 100 and 1000.

Logarithm of 100 = 2.000000
Logarithm of 1000 = 3.000000

Divide by 3.000000 2.000000

Log of the least term 100 added 3.000000

Log of the 1st mean 101.467384 2.000000
Log of the 2d mean 102.956014 2.000000
Log of the 3d mean 104.467048 2.000000
Log of the greatest term 106. 2.000000

LOGIC.---The professional business of logic is to explain the nature of the human mind, and the proper manner of conducting its several powers, in order to the attainment of truth and knowledge.

There are two fundamental prophecies of logic: the first, that the logic of the least term, have endeavored first to define and describe the several faculties and operations of the human mind, as perception, judgment, memory, invention, &c. The second is to lay down rules for correct reasoning and argument. Every act of the judgment they term a proposition, and all propositions are either affirmative or negative. All questions or arguments they reduce to syllogisms; that is, from two axioms or propositions (called terms, in the technical language) laid down, they deduce a third, or conclusion, and the previous propositions they divide into major and minor. Thus, let the question be, whether God is an intelligent being? Here the major or principal proposition proceeds from the word intelligent, and the minor respects God. They would then arrange the syllogism as follows:

Affirmative

Minor

Major

Conclusion.

Let God have disposed creation in right and perfect order;

Therefore God is an intelligent being.

3. They next class or arrange the different kinds of syllogisms according to the nature of them. Propositions are not only affirmative and negative, but they are also particular or universal. These syllogisms will vary, not only as the major or minor proposition is negative or affirmative, but as either is an universal or particular affirmative.
chalky, or sandy soils. It is advantageously cultivated along with clover, and springs earlier than other grasses, supplying food for cattle at a time when it is most difficult to be obtained. - Cattle, sheep, and, eat it; goats are not fond of it.

2. The temulentum, or white dandel, grows spontaneously in ploughed fields. If the seeds of this species are matted with barley, the ale soon occasions drunkenness; mixed with bread-corn, they produce but little effect, unless the bread is eaten hot.

LONCHITTS, spleenwort, a genus of the cryptogamia class of plants, the fructifications of which are arranged into fleshy filaments, and disposed separately under the surfaces of the leaves. There are five species. The leaves of this plant are of use in healing wounds, and in preventing inflammations of them: they are also used against the spleen. The root is aperient and diuretic.

LONGEVITY, long life. The duration of human life is a subject so universally interesting, that instances of persons who have considerably exceeded the usual term of life have at all times attracted notice, although very few attempts have been made to ascertain the circumstances under which life may be prolonged to its greatest extent. Buffon, d'Arsonval, d'Herblay, d'Herbelin, and a few others who have noticed this subject, appear to have considered but a very small number of the instances of longevity which have occurred. Mr. J. Easton, in order to supply better materials for others, published, a few years since, a much greater collection of instances of this kind, though probably but a small part of what have actually occurred. His list consists of 1712 persons, who are stated to have died at the following ages:

<table>
<thead>
<tr>
<th>Age (years)</th>
<th>Persons</th>

1712

Such a number of instances would furnish many useful conclusions; but most accounts of this kind contain little more than the name, age, and place of the death of the person mentioned, from which little or no information can be gained. Sir J. Sinclair, in an Essay on Longevity, has endeavoured to excite a more general interest on this subject, which has by no means been investigated with the attention it deserves.

That long life is principally on account of the laws of nature, appears an indisputable fact; but from all appearances which have been made, it likewise appears, that there are other circumstances which may considerably influence the life of men, and are perhaps the most certain is descent from long-lived ancestors. Dr Rush, of Philadelphia, remarks, that he has not found a single instance of a person who lived to be 80 years old, of whom this was not the case; and the accounts collected by others strongly confirm this observation.

The climate of some countries has been supposed to be much more favourable to longevity than others: thus Mr. Whitehurst, asserted, that Englishmen in general were longer-lived than North Americans; and Mr. W. Barlow, endeavoured to prove the contrary: but whatever inferences of this kind national partiality may attempt to support, more extensive observations will in general confirm the conclusion, that although longevity evidently prevails more in certain districts than in others, and those regions which lie within the temperate zones are best adapted to promote long life, yet it is by no means confined to any particular district, nor can remarkable instances of it be produced both from very hot and very cold countries. It is highly probable that the human frame is so constituted as to adapt itself easily to the atmosphere and peculiarities of the country in which it receives life, or even into which it is afterwards removed. Thus France and Sweden are countries differing materially in soil and climate: the general age of life of the inhabitants in both is very different; yet the usual rate of mortality has been found nearly the same in both. Men can live equally well under very different circumstances. It is a small change that machines for the health of the inhabitants than others; and the cause of this superiority is chiefly a free circulation of air, uncontaminated with the noxious vapours and exhalations which destroy its purity in other parts, as remarkable instances of it almost universally found more healthy than low and muddy places, or than close and crowded cities.

From a list of 145 persons who are recorded to have lived to the age of 120 years and upwards, it appears, that more than half were inhabitants of Great Britain and Ireland. Of these, 63 of England and Wales, 23 of Scotland, 29 of Ireland, and 30 of other countries.

The number of instances in Scotland, compared with those in England and Ireland, shews by this account to have been more than twice the proportion of the population, which certainly seems to shew that the climate of the former is very favourable to long life. The great proportion of inhabitants of Great Britain and Ireland, though perhaps arising in some measure from circumstances of great age not being so generally noticed and recorded in other places, at least shews, that these countries are not unavourable to longevity.

It is a fact pretty well established, that more males are born than females; it is also well known, that in almost every form which animal life assumes, the male appears to possess a smaller degree of bodily strength to the female. From these circumstances it might be expected that the number of males living would be found greater than that of the females, and that in general the latter did enjoy a greater duration of life. On the contrary, however, has been asserted, and evidence produced which appeared to justify such an opinion; but it seems probable, that in forming the accounts from which the number of females living appeared greater than that of the males, sufficient attention was not paid to the number of males engaged chiefly abroad in the army and navy, and of the emigrations to foreign parts being chiefly of males. That the male constitution is naturally more durable than that of females, may be inferred from the list more referred to of 145 persons, who have attained unusually great age, more than two-thirds of the number being males. Dr. Hufeland remarks, that the equilibrium and pliability of the female body seems, for a certain time, to give it some advantage, and to render it less susceptible of injury from destructive influences than that of men; but that male strength is, without doubt, necessary to arrive at a very great age. More women are, however, much longer-lived; and if the registers of mortality, from which tables of the probability of the duration of human life are formed, were more extensive, and comprehended a greater number of years, so as to lend the instances of great longevity, the difference between the value of male and female lives would appear less than it is supposed to be, and probably the sum of life of each sex would nearly to equality.

The form of the individual appears to be of considerable importance: moderate-sized and well-proportioned persons have certainly the best chance of long life. There are, however, a few instances, of a different description having attained considerable age. Mary Jones, who died in 1783, at Worm, in Shropshire, aged 100, was only two feet eight inches in height, very middling and small; and James McDonald, who died near Cork in the year 1760, aged 117, was seven feet six inches high.

Matrimony, if not entered into too early, appears to be very conducive, both to a long life, the proportion of unmarried persons attaining great age, being remarkably small; Dr. Rush says, that in the course of his enquiries, he met with only one person beyond eighty years of age, who had never been married. This is a very limited remark; Mrs. Malton, who died in 1733, aged 105; Ann Kerney, who died the same year, aged 110; Martha Dunridge, who died in 1752, in the 100th year of her age, and never married, who died in 1753, aged 104, had never been married: and in the list prefixed to Sir John Sinclair's Essay on Longevity, of pensioners in Greenwich hospital, who were upwards of eighty years of age, there are sixteen who never were married: the same list, however, contains five times as many persons who had been married, and other accounts are in a still greater proportion.

The Chinese erect triumphal or honorary arches to the memory of persons who have lived, a century, thinking, that without a sober and virtuous life it is impossible to attain so great an age. Temperance is certainly the best security of health; and no man can reasonably expect to live long who impairs the vital powers by excess, which converts the most natural and beneficial enjoyments into the most certain means of destruction. The few instances of individuals who, notwithstanding their licentious mode of life, have attained considerable age, cannot be put in comparison with the immense number whose lives have been materially shortened.
LONGITUDE.

Suppose I examine the rate of a watch for 30 days; on some of those days I find it has gained, and on some it has lost: add together all the quantities it has gained, and suppose they amount to 17°; and together all the quantities it has lost amount to 15°; then upon the whole, it has gained 2° in 30 days; and this is called the mean rate for that time; and this divided by 30, gives 0°.133 for the mean daily rate of gaining: so that if the watch had been exactly regular, 0°.133 every day, at the end of the 30 days it would have gained just as much as it really did gain, by sometimes gaining and sometimes losing. Or you may get the difference between what the clock was too fast or too slow on the first and last days of observation, if it be too fast or too slow on each day; but take the sum, if it is too fast on one day and too slow on the last day, &c; the difference is the mean rate of gaining. But if the watch was too fast on the first day 18°, and too fast on the last day 32°, the difference is 14° and the mean daily rate of gaining, is 0°.463, the mean daily rate of gaining.

Thus, if the watch was too fast on the first day 18°, and too fast on the last day 32°, the difference is 14° and the mean daily rate of gaining, is 0°.463, the mean daily rate of gaining. But if the watch was too fast on the first day 18°, and too fast on the last day 32°, the difference is 14° and the mean daily rate of gaining, is 0°.463, the mean daily rate of gaining.

In the year 1726, Mr. John Harrison pro-
LONGETHE.

duced a time-keeper of his own construction, which did not err above one second in a month for ten years together; and in the year 1736 he had a machine tried in a voyage to and from Lisbon, which was the means of correcting an error of almost a degree and a half in the compass. He returned, and in 1739 published a paper on the subject. His own experiments were supported by those of his contemporaries, and it is a great question whether any improvement in the art of time-keeping was ever made by any other person. He had also a very great exactness in the regulation of his time-keepers, for he had them adjusted at the time of the day, when the moon was new, and he had no more than a few minutes of the mean time, for which this last time-keeper was sent down to the Royal Observatory at Greenwich, to be tried in consequence of his success. Mr. Harrison received public encouragement to proceed, and he made three other time-keepers, each more accurate than the former, which were tried successively in the years 1739, 1758, and 1791; the last of which proved so much to his own satisfaction, that he applied to the commissioners of the longitude to have this instrument tried in a voyage to the West Indies according to the directions of the statute of the 12th of Anne above cited. Accordingly, Mr. William Harrison, son of the inventor, embarked in November 1781, on a voyage for Jamaica, and in the beginning of the 17th year of his age, he returned to England with the time-keeper, in March 1782, when he found that it had err'd in the fourth month, no more than 1° 40' 45" in time, or 285 minutes of longitude; whereas the act required that the act should be corrected by the geographical miles, or minutes of a great circle, in such a voyage. Mr. Harrison now claimed the whole reward of 20,000l., offered by the said act, but some doubts arising in the minds of the commissioners, as to the true situation of the island of Jamaica, and the manner in which the time at that place had been found, as well as to Portsmouth, and it being further suggested by some, that although the time-keeper happened to be right at Jamaica, and after its return to England, it was by no means a proof that it had been always so in the intermediate time; another trial therefore was therefore proposed, in a voyage to the island of Barbadoes, in which precautions were taken to obviate as many of these objections as possible. Accordingly the commissioners previously sent one of their own persons to make astronomical observations; and, by the aid of their time-keeper, which, when compared with other corresponding ones made in England, would determine beyond a doubt, its true situation; and Mr. William Harrison again set out with his father's time-keeper, in March 1764, the watch having been compared with equal altitudes at Portsmouth before he set out, and he arrived at Barbadoes about the middle of May; where, on comparing it again by equal altitudes of the sun, it was found to shew the difference of longitude between Portsmouth and Barbadoes to be 3° 35m. 3s.; the true difference of longitude between these places, by astronomical observation, being 3° 3m. 20s.; so that the error of the watch was 38s., or 10° 45' 20" of longitude. In consequence of this and the former trials, Mr. Harrison received one moiety of the reward offered by the 12th of queen Anne, after explaining the principles on which his watch was constructed, and delivering this, as well as the three former, to the commissioners of the longitude for the use of the public; and he was promised the other moiety of the reward, when other time-keepers should be made.
still further improved under his direction, by the
life Mr. Charles Mason, by several new
equations, and the whole computed to tenths of a second. These tables, when
compared with the above-mentioned series of ob-
servations, a proper allowance being made for the
ternal error of observation, seem always to give the
longitude in the heavens correctly within 30 seconds of a degree;
which greatest error, added to a possible error of one minute in taking the longitude
differences from the sun or a star at sea, will at
a medium only produce an error of 42 minutes of longitude. To facilitate the use of
these tables, Dr. Maskelyne proposed a nauti-
cal Ephemeris, the scheme of which was
adopted by the commissioners of longitude,
and first executed in the year 1767, which
from that time has been regularly continued.
But as the rules that were given in the
appendix to one of these publications, for cor-
recting the effects of refraction and parallax,
were thought too difficult for general use,
they have been reduced to tables. So that,
by the help of the ephemerides, these tables,
and others that are also provided by the
Board of Longitude, the calculations relating
to the longitude, which could not be per-
formed by the most expert mathematician
in less than four hours, may now be com-
puted with great ease and accuracy in half an hour.

As this method of determining the longitude
depends on the use of the tables an-
nually published for this purpose, those who
wish for further information are referred to
the instructions that accompany them, and
particularly to those that are annexed to the tables requisite to be used with the Astro-
nomical and Nautical Ephemerides.

4th. The phenomena of Jupiter's satellites have commonly been preferred to those
of the moon, for finding the longitude; because
they are less liable to parallaxes than these
are, and besides they afford a very conno-
sognous observation whenever the planet
is above the horizon. Their motion is very
very rapid, and may be calculated for every hour.

Now, to find the longitude by these satel-
ilites: with a good telescope observe some of
their phenomena, as the conjunction of two of
them, or of one of them with Jupiter, &c.
and at the same time find the hour and minute,
from the altitudes of the stars, or by
means of a clock or watch, previously regu-
lated for the place of observation; then, con-
sulting tables of the satellites, observe the
time when the same appearance happens in
the meridian of the place for which the tables
are calculated; and the difference of time,
as before, will give the longitude.

The eclipses of the first and second of Jupi-
ter's satellites are the most proper for this
purpose; and as they happen almost daily, they
afford a ready means of determining the
longitude of places at land, having indeed contributed much to the modern improve-
ments in geography; and if it were possible to
observe them with proper telescopes, in a
ship under sail, they would be of great ser-
vice in ascertaining its longitude from time
to time. To obviate the inconvenience to
which these observations are liable from the
motion of the ship, Mr. Irwin has written
what he called a marine chair: this was tried
by Dr. Maskelyne, in his voyage to Barba-
dos, when it was found that no benefit
could be derived from the use of it. And
indeed, considering the great power requi-
site in a telescope proper for these ob-
servations, and the violence as well as irregulari-
ties in the motion of the ship, it is
that the complete management of a telescope
on board ship will always remain among the
desiderata in this part of nautical science.

And further, since all methods that depend
on the phenomena of the heavens, have also
this other defect, that they cannot be ob-
served at all times, this renders the improve-
ment of timekeepers of the greater impor-
tance.

LONICERA, honeysuckle, a genus of the
monogynia order, in the pentandria class
of plants. The corolla is monopetalous and ir-
regular; the berry polyspernum, bilocular,
and inferior. There are 19 species, of which
the most remarkable are:

1. The alpigena, or upright red-berried
honeysuckle, rises with a shrub, short, up-
right stem, four or five feet high.

2. The cereum, or blue-berried hone-
ysuckle, has a rather shrub-like
stem, which is commonly 4 or five feet
high, and many white flowers proceeding
from the sides of the branches.

3. The nigra, or black-berried upright
honeysuckle, with a shrubby stem three or
four feet high, and white flowers succeed-
ning by single and distinct black berr-
ies.

4. The tartarica, or Tartarian honeysuckle,
with a shrubby upright stem, three or four
feet high, heart-shaped opposite leaves,
and white flowers succeeded by red ber-
rries, sometimes distinct, and sometimes
double.

5. The dicrilla, or yellow-flowered Area-
cadian honeysuckle, with shrubby upright
stems, to the height of three or four feet,
and clusters of pale yellow flowers,
appearing in May and June, and sometimes
continuing till autumn, but rarely ripeing
seeds here.

6. The xystostoma, or fly honeysuckle,
with a strong shrub stem, branching erect
to the height of seven or eight feet, and erect
white flowers proceeding from the sides of
the branches.

7. The symphoricarpos, or shrubby St.
Peter's-wort, with a shrubby rough stem,
four or five feet high, and small greenish
flowers.

8. The perennialum, or common climb-
ing honeysuckle, has two principal varieties,
viz. The English wild honeysuckle, or wood-
bine of our woods and hedges, and the Dutch
or German honeysuckle, with a shrubby de-
clinated stalk, and long trailing purplish
branches, forming large beautiful red flow-
ers of a fragrant odour, appearing in June
and July.

9. The caprifolium, or Italian honeysuckle,
with shrubby terminated stalks, or by
long slender trailing branches, terminated by
verdant or whitish white clusters of close-sit-
ing flowers, very fragrant, and white, red,
and yellow colours.

10. The camporum, or evergreen trump-
eter-flowered honeysuckle, with a shrubby de-
clinated stalk, sending out long slender trailing
branches, terminated by naked ver-
dicillate spikes, of long, unreflected, deep-
scarlet flowers, very beautiful, but of little
fragrance.

LOOF, in the sea language, is a term used
in various senses; thus the loof of a ship
is that part of her aloft which lies just before
the chest-tree; hence the guns which lie
there are called loof-pieces: keep your loof,
signifies, keep the ship near to the wind:
to close by the wind: loof up, is to keep nearer
the wind: to spring the loof, is when a ship
that was going large before the wind, is brought
close by the wind.

LOOM-TACKLE, is a tackle in a ship which
serves to lift goods of small weight in or out
of her.

LOOKING-GASSES. See Optics.

LOOM, the weaver's frame, a machine
whereby several distinct threads are woven
into one piece. Looms are of various struc-
tures, accommodated to the various kinds of
materials to be woven, and the various man-
ner of weaving them, viz. for woollens, silks,
and cloths ; and sometimes for gowns, and other
works, as tapestry, ribands, stockings, &c.

See Weaving.

The weaver's loom-engine, otherwise called
the Dutch loom-engine, was brought into use
from Holland to London, in or about the
year 1676.

The lower compartment of Plate Lock and
Loom, represents a loom for weaving silks or
other plain work. A, fig. 6, is a roll called
the loof, on which the warp is wound as it is
wove; at one end it has a ratchet-wheel a,
and a click to prevent its running back; at
the same end it has also four holes in it, and
is turned by putting a stick in these holes; at
the other end a roller b, on which the yarn is wound; this has two small
cords bb wrapped round it, the ends of
which are attached to a bar d, which has a
weight D hung to it; by this means a fric-
tion is caused, which prevents the roll turn-
ing by accident. EF are called lambs; they
are composed of two sticks eF, between
which are fastened a great number of threads;
which are called the warp, as passed; the
first thread of the warp goes through
the loops of the lambs E, the next attached to
the lamb F; and so on alternately; by this
means, when the weaver presses down one of
the treadles with his foot, and raises the other,
one lamb draws up every other thread,
and the other sinks all the rest, so as to make
an opening between the sets of thread; LL
is a frame moving up a centre at the top of
the frame of the loom; the longer part of
this frame is shewn in fig. 8; LL are the two
uprights of the frame, / is the bar that con-
nects them, M is a frame carrying a great
number of pieces of split reeds or sometimes fine
wire at equal distances; between these threads
of the warp are passed; the frame M is
supported by a piece of wood m called the
shuttle-race, which is fastened into the front of the pieces LL; each end of this piece has boards nailed to the sides, so as to form troughs NO; at a small distance above each trough are fixed two very smooth wooden pieces mn; their use is to guide the two pieces py, called peckers or drivers; to each of these pieces a string is fastened, and these strings are tied to a piece of wood, which the weaver holds in his hand, and by matching the stick to either side, draws the peckers forward very quick, and gives the shuttle, fig. 7, (which is to be laid in the trough before the pecker) a smart blow, and drives it along across the race as into the other trough, where it pushes the pecker along to the end of the wire, ready for the next stroke which throws it back again, and soon. Fig. 7 represents the under side of the shuttle on a larger scale. LOOP, in the iron works, denotes a part of a large morse through the middle of it, in which is placed a quill a containing the yarn b, in a piece of glass, called the eye of the shuttle, with a body, cd, through which comes the thread of the frame LL with its left; presses his foot on one of the treadles G1, which by means of the lambs EF, as before described, divides the warp; he then snatches the stick PI and by that means throws the shuttle, fig. 7, which unwinds the thread in it, and leaves it lying between the threads of the warp; he then relieves the shuttle before he keeps down, and presses down the other, while he draws the frame LL towards him, and then returns it. The use of this is to beat the last thread thrown by the shuttle close up to the one that was thrown before it by the split peckers M, fig. 8, which has brought the frame LL back to its original position, and again divided the warp by the shuttle, he throws the shuttle again: when he has in this manner finished about 12 or 14 inches of the piece, he will have the roll A with the stick, as before described. Some very expert weavers will throw the shuttle and perform the other operations at the rate of 120 times per minute.

Loom-gale, a gentle easy gale of wind, in which a ship can carry her topsails on.

LOOP, or a piece of a saw or block of cast iron, broken or melted off from the rest.

LOPHIUS, fishing-frog, toad-fish, or sea-devil, a genus of the branchiosseous order of fishes, whose head is in size equal to all the rest of the body. There are three species, the most remarkable of which is the piscatorius, or common fishing-frog, an inhabitant of the British seas. This singular fish grows to a large size, some being between four and five feet in length; and Mr. Pennant mentions one taken near Scarborough, whose mouth was a yard wide. The fishermen on that coast have a great regard for this fish, from the end of the season it is a great enemy to the dog-fish; and whenever they take it with their lines, set it at liberty. The head of this fish is much larger than the whole body, is round at the circumference, and flat above; the mouth of prodigious widthiness. The under jaw is much longer than the upper; the jaws are full of slender sharp teeth; in the roof of the mouth are two or three rows of the same. On each side the upper jaw is two sharp spines, and others are scattered about the upper part of the head. The body grows slender near the tail, the end of which is quite even. The colour of the upper part of this fish is dusky; the lower part white; the skin smooth.

LORANTHUS, a genus of the monocotyledonous order, in the hexadernia class of plants, and in the natural method ranking under the 14th order, aggregata. The genus is inferior; there is no calyx; the corolla is sessile and revolute; the stamens are at the top of the petals; the berry is monospermous. There are 18 species, natives of America.

LORD. See Peer.

LORD'S DAY. All persons not having a reasonable excuse shall resort to their parish church or chapel (or to any congregation of religious worship allowed by thetoleration act) on every Sunday, on pain of punishment by the censures of the church, and of forfeiting 1s. to the poor for every offence; to be levied by the churchwardens by distress, by warrant of one justice.

The hundred shall not be answerable for any robbery committed on the Lord's day.

No carrier shall travel, or drover drive cattle, on the Lord's day, under the penalty of 20l.

No person upon the Lord's day shall serve or execute any writ, process, warrant, order, judgment, or decree (except in cases of treason, felony, or breach of the peace), but the service thereof shall be void.

LOTTERIES are declared to be public nuisances, 5 Geo. I. c. 9; but for the public service of the government, lotteries are frequently established by particular statutes, and managed by special officers and persons appointed.

By statute 42 Geo. III. c. 54, lottery-office keepers are to pay 50l. for every licence in London, Edinburgh, and Dublin, or within twenty miles of either, and 10l. for every licence in every other place. Any unlicensed person shall deposit 30 tickets with the receiver-general of the stamp-duities, or licence to be void.

By statute 22 Geo. III. c. 47, lottery-office keepers must take out a licence; and officers are to be open only from eight in the morning to eight in the evening, except the Saturday evening preceding the drawing. The sale of chances and shares of tickets, by persons not being proprietors thereof, is prohibited under penalty of 50l.; and by 42 Geo. III. c. 119, all games or lotteries called little goes, are declared public nuisances, and all persons keeping any office or place for any game or lottery, not authorized by law, shall forfeit 500l. and be deemed rogues and vagabonds. The proprietor of a whole ticket may nevertheless insure it for its value only, with any licensed office for the whole time of drawing from the time of insuring, under a bona fide agreement without a stamp.

LOTUS, or birds-foot trefoil, a genus of the deciduous order, in the diadelphia class of plants, and in the natural method ranking under the 32d order, papilionaceous. The legume is cylindrical, and very erect, the end closing upwards longitudinally; the calyx is tubular. There are 23 species, but only six are usually cultivated in our gardens.

1. The siliquous, or winged pea, has trailing, slender, branchy stalks, about a foot long, with trifoliolate oval leaves, and from the weaver legumes, large, yellow, or scarlet, red-figured flowers, one on each footstalk, succeeded by tetragonal solitary pods, having a vernaceous wing or lobe, running longitudinally at each corner. It flowers in June and July; and the seeds ripe in autumn.

2. The crucifer, or Cretan silvery lotus. 3. The Jucundus, or black lotus of St. James's island. 4. The hisbatus, or hairy Italian lotus. 5. The doreynium, white Austrian lotus, or double-twig of Montpellier. 6. The ecuils, with yellow flowers.

The first species is a hardy annual. The other species may be propagated either by seeds or cuttings, but require to be kept in pots or boxes in the greenhouse during the winter seasons.

LOTUS, or Knights of St. Louis, the name of a military order in France, instituted by Louis XIV. in 1693.

LOUSE. See Pediculus.

LOXIA, a genus of birds of the order of passerines, the distinguishing characters of which are: the bill is strong, convex above and below, and very thick at the base; the nostrils are small and round; the tongue is as if cut off at the end; the toes are four, placed three before and one behind, excepting one species, which has only two toes before and one behind. The most remarkable are:

1. The cur' rostra, or common cross-bill, is about the size of a lark, is known by the singularity of its bill, both mandibles of which turn outwards, the general colour of the plumage in the male is a red or lead, inclining to rose-colour, and more or less mixed with brown; the wings and tail are brown; the legs black. The female is the same colour, but tends to a chocolate or brown, blended with brown in those parts where the male is red. This species is a constant inhabitant of Sweden, Germany, Poland, Switzerland, Russia, and several parts of Africa, where it breeds, but migrates sometimes in vast flocks; it is now and then the case in respect to England; for though in some years a few are met with, yet in others it has been known to visit us by thousands, sitting on such spots as are planted with pines, for the sake of the seeds, which are its natural food; it is observed to hold the cone in one claw like the parrot, and to have all the actions of that bird when kept in a cage. It is also found in North America and Greenland; and is said to make its nest in the highest parts of the fir-trees, fastening it to the branch with the resinosous matter which exudes from the trees.

2. The coccothraustes, or hawfinch, is in length seven inches. This species is ranked among the British birds; but only visits this country occasionally, and for the most part in winter, and is never known to breed here. It is more plentiful in France. It feeds on oak and elm seeds, &c., and is noted for the great strength of the bill, it cracks the stones of the fruit of the haws, cherries, &c., with the greatest ease.
3. The pyrrhula, or bullfinch, is so generally known as almost to supersede description. This species is common in most parts of the Continent of Europe, throughout Russia and Siberia, at which last place it is caught for the table. In winter it approaches gardens and orchards, and has been generally stipulated for making havoc among the buds of trees. It is of a very brilliant black, with oyster or greenish white, and is very destructive when once their entrances are gained; however, it would appear, that the object of these birds is not the bud, but "the worm in the bud," and that this species, in conjunction with various other species of small birds, are the destroyers of every hope of fruit, on any trees, bringing forward a numerous race already in a caterpillar state, that now issue from their concealments, and make their excursion along the budding branches, and would probably, under the most favorable circumstances, make those useful instruments for its preservation, whose young are principally fed by eating caterpillars. The bullfinch, in its wild state, has only a plain note; but when tame, it becomes remarkably musical, and will whistle at any time after a pipe, or to whistle any notes in the best manner; it seldom forgets what it has learned; and will become so tame as to come at call, perch on its master's shoulders, and in some cases, think nothing of affixing a superficial lesson. They may be also taught to speak, and some thus instructed are annually brought to London from Germany.

4. The cardinals, or cardinal grosbeak, is near eight inches in length. The bill is stout, and of a pale-red colour; the irides are hazel; the head is greatly crested, the feathers rising up to a point when erect; round the eye are found black and red rings, and the rest of the bird is of a fire-red. The female differs from the male, being mostly of a reddish brown. This species is met with in several parts of North America, and has attained the highest degree of brilliant notice, not only for the fineness of its song, the note of which resembles that of the nightingale.

5. The orix, or grenadier grosbeak, is about the size of a house-sparrow. The forehead is red-brown, and the upper surface of the breast and belly the same; the wings are brown, with pale edges; and the rest of the body of a beautiful red colour. These birds are inhabitants of Saint Helen; they are also in plenty at the Cape of Good Hope, where they frequent wetery places that abound with reeds, and among which they are supposed to make their nests. If, as is supposed, this is the same with Kolben's finch, he says that the nest is of a peculiar construction, made of reeds with small twigs, interwoven very closely and tightly with cotton, and divided into two apart nests with but one entrance, the upper for the male, the lower for the female, and is so tight as not to be penetrated by any weather. He adds, that the bird is scarlet only in the summer, being in the winter wholly ash-coloured. These birds, seen among the green reeds, are said to have a wonderful effect: for, from the brightness of their colours, they appear like so many scarlet lilies. See Plate Nat. Hist. fig. 253.

6. The penalis, or penalis grosbeak, (the toady-bird of Fryer) is about the size of the house-sparrow; the bill is black; the irides are yellow; the head, throat, and fore-part of the neck, of a beautiful red; the back, black, and tail, are black; the wing-covers, brown, edged with white; quills brown, with greenish edges; and legs a dull red; the wings reach half-way on the tail. This species inhabits Abyssinia, and frequents woods, and is a solitary species.

According to Linnaeus there are 48 species of the loxia.

7. The Bengalensis, or Bengal gros beak, is a trifle bigger than a house-sparrow; the female lays three or four eggs.

8. The Bengali gros beak, is about the size of a bullfinch; the general colour of the body above is a rufous brown, the under parts whitish. It inhabits the interior country of the Cape of Good Hope, and is found in a wild state, or in gardens in the same islands. These birds, according to our author, live together in large societies, and their mode of multiplication is extremely uncommon. They lay in a species of mound, which is of an uncommon size. In one described by Paterson, there could be no less a number than from 800 to 1000 resting under the same roof. He calls it a roof, because it perfectly resembles a roof of a thatched house, and the ridge forms an angle so acute and so smooth, projecting over the entrance of the nest below, that it is impossible for any reptile to approach them. The industry of these birds, in the construction of this roof (by an author) to that of the bee: throughout the day they appear to be busily employed in carrying a line species of grass, which is the principal material they employ for the purpose; in some cases, it is so well covered, as well as for additions and repairs. Though my short stay in the country was not sufficient to satisfy me by ocular proofs, that they added to their nest as they annually increased in numbers, still from the many trees which I have seen hewn down with the weight, and others which I have observed with their boughs completely covered over, it would appear that this is really the case. When the tree which is the support of this aerial city is obliged to give way to the increase of weight, it is obvious that they are no longer protected, and are under the necessity of rebuilding in other trees. One of these deserted nests I had the curiosity to break down, so as to inform myself of the internal structure of it, and found it equally ingenuous with that of the external. There are many entrances, each of which forms a regular street, with neat rows of sided rooms at about two inches distant from each other.

9. The tridactyla, or three-toed grosbeak, (the gufo balato of Buffon) has only three toes, two before and one behind. The bill is toothed on the edges; the head, throat, and fore-part of the neck, are of a beautiful red; the other part of the neck, back, and tail, are black; the wing-covers, brown, edged with white; quills brown, with greenish edges; and legs a dull red; the wings reach half-way on the tail. This species inhabits Abyssinia, and frequents woods, and is a solitary species.

According to Linnaeus there are 48 species of the loxia.

LOZENCE, Lozange, rhombus, in geometry, a triangle or parallelogram, figure consisting of four equal and parallel sides, two of which opposite angles are acute, and the other two obtuse; the distance between the two obtuse ones being always equal to the length of one side; when the sides are unequal, this figure is called a rhomboid.

LOZENCE, in heraldry, a rhombus, or figure of equal sides, but unequal angles.

LOZENGIE, in pharmacy, the same with what is usually called the lozenge.

LUCANUS, stag chaffer, a genus of insects of the order coleoptera: the generic character is, antennae clavated, with compressed tip, divided into lamellae on the inner face; jaws strongly expanded, elongated, and toothed. The principal species is the lucanus cervus, commonly known by the name of the stag-beetle, or stag-chaffer. It is the largest of all the European coleopterous insects, sometimes measuring nearly two inches and a half in length, from the tip of the jaws to the end of the body. Its general colour is a deep chestnut, with the thorax and head, which is of a sparrow form, of a blacker cast; and the legs and under-parts are chestnut-colour, excepting that the wings and the wings, which, except during flight, are concealed under the shells, are large, and of a fine pale yellowish-brown. This remarkable insect is chiefly found in the neighbourhood of oak-trees, delighting in the sweet exudation or honey-dew so frequently observed on the leaves. Its larva, which perfectly resembles a caterpillar, is sometimes found in nearly two inches and a half in length, in the hollows of oak-trees, residing in the fine vegetable mould usually seen in such cavities, and feeding on the softer parts of the decayed wood. It is of very considerable size, and the shell-bones are reddish-brown in colour; and when stretched out at full length, measures nearly four inches. When arrived at its full size, which, according to some, is hardly sooner than the fifth or sixth year, it flies, by frequently turning itself, and moistening it with its glutinous saliva, a smooth oval hollow in the earth, in which it lies, and afterwards remaining perfectly still for the space of near a month, winters itself in its skin, and commences pupa or chrysalis... It is now of a shorter form than before, of a rather deeper colour, and exhibits in a striking manner the rudiments of the large extended jaws and broad head, conspicuous in the perfect insect: the legs are also proportionally larger and longer than in the larva state. The ball of earth in which this chrysalis is contained is considerably larger than a hen's egg, and of a glistening surface, but perfectly smooth and polished within. The chrysalis lies about three months before it gives birth to the complete insect, which usually emerges in the months of July and August. The time, however, of this insect's
growth and appearance in all its states varies much, according to the difference of seasons. It is not very uncommon in many parts of England.

The commonly supposed female differs so much in appearance from the male, that it has by some been considered as a distinct species. It is not only smaller than the former, but totally destitute of the long and large ramified jaws, instead of which it has a pair of very short curved ones, slightly dentilicated or denticulated on one side: the head is also of considerably smaller diameter than the thorax. In point of colour it resembles the former.

The exotic species of this genus are mostly natives of the cold regions, in particular, frequently found in Virginia, is so nearly allied to the English stag-beetle as hardly to differ, except in having fewer denticles or divisions on the jaws.

A highly esteemed species has lately been discovered in New Holland. This differs from the rest in being entirely of a beautiful golden-green colour, with short, sharp-pointed, denticulated jaws of a brilliant coppery-colour. The breadth of the width of the insect is rather more than an inch. There are seven species of the lucanus.

LUCIDA, in astronomy, an appellation given to several fixed stars on account of their surpassing brilliancy, as a star of the second magnitude in the northern crown; the lucida hydra, or cor hydrae; and the lucida lyra, a star of the first magnitude in that constellation.

LUDWIGIA, a genus of the monogyne order, in the tetragonia class of plants, and in the natural method ranking under the 17th order, calycanthaceae. The corolla is tetra- petal; the capsule tetragonal, quadrilateral, inferior, and polyperspermous. There are four species, annuals of the West Indies.

LUES. See Medicine.

LUMBAGO. See Medicine.

LUMBICRUS, the worm, in zoology: a genus of insects belonging to the order of vernum intestinus. The body is cylindrical, annulated, with an elevated belt near the middle, and its side. One of the uterus is the genus coreus, a star of the second magnitude in the northern crown; the lucida hydra, or cor hydrae; and the lucida lyra, a star of the first magnitude in that constellation.

LUMBICRUS, the worm, in zoology: a genus of insects belonging to the order of vernum intestinus. The body is cylindrical, annulated, with an elevated belt near the middle, and its side. the form given to it. It is generally rolled into cylinders of a convenient size. These are to be applied, by folding them, to the joints of the veins of England, which ought to be perfectly dry; because the least moisture would prevent the lute from adhering. When the joints are closed with this fat-lute, the whole is to be covered with slips of linen seconded with lute and with veils of gauze. These slips are to be fastened with pack-thread. The second lute is necessary to keep on the fat-lute, because the latter remains soft, and does not become solid enough to stick on closely.

Ground lissead made into a paste with water makes also a very useful lute for most occasions.

LUTHERANS, the Christians who follow the opinion of Martin Luther, one of the principal reformers of the church in the sixteenth century. See Gregory's Church History, vol. ii.

LYCÉON. See Surgery.

LYCHNIS, campion, a genus of the pentapigmy order, in the pentadactyla class of plants, and in the natural method ranking under the 23rd order, Caryophyllaceae. The plants are, in general, compact and smooth; there are five unguiculate petals, with the segments of the limbs almost bident; the capsule quinquilocular. There are 12 species, the principal are, 1. The chalybean, or clavate Lyc. 2. The diurna; the varieties are, the common single red-flowered bachelor's button, double red, double white, and single white-flowered. The double variety is the only one ornamented in their bloom; the flowers large, very double, and continue long in blow; the single red sort grows wild by ditch-sides and other moist places of England, from which the doubles were accidentally obtained by culture in gardens. 3. The viscaria, or viscous German Lyc., commonly called catch-fly. Of this also there are varieties with single red flowers, with double red flowers, and with white flowers. The double variety is considerably the most eligible for general culture, and is propagated in plenty by parting the roots. All the varieties of this species emit a glutinous liquid matter from their stalks, flies happening to light on them sometimes stick and entangle themselves, whence the plant obtains the name catch-fly. 4. The flos coccii, cocciflorus Lyc. used for the cultivation of Lyc. Cus. mossa, a genus of the natural order of muco, belonging to the Caryophyllaceae class of plants. The anthers are bivalved and sessile; there are no calyptrae. There are there species, of which the following are remarkable: 1. The clavatum, or common club-moss, is common in dry and mountainous places, and in fir forests. The stalk is prostrate, branched, and creeping from a foot to two or three yards long; the radications are formed of lacerated segments, in some varieties reliefed. The powder is believed to be the seeds, which through a microscope appear of a spheroidal form, and to be annexed to elastic hairs. 5. The Lyc. Cus. mossa, a genus of the natural order of mucus, belonging to the Caryophyllaceae class of plants. The anthers are bivalved and sessile; there are no calyptrae. There are there species, of which the following are remarkable: 1. The clavatum, or common club-moss, is common in dry and mountainous places, and in fir forests. The stalk is prostrate, branched, and creeping from a foot to two or three yards long; the radications are formed of lacerated segments, in some varieties reliefed. The powder is believed to be the seeds, which through a microscope appear of a spheroidal form, and to be annexed to elastic hairs. 6. The Lyc. Cus. mossa, a genus of the natural order of mucus, belonging to the Caryophyllaceae class of plants. The anthers are bivalved and sessile; there are no calyptrae. There are there species, of which the following are remarkable: 1. The clavatum, or common club-moss, is common in dry and mountainous places, and in fir forests. The stalk is prostrate, branched, and creeping from a foot to two or three yards long; the radications are formed of lacerated segments, in some varieties reliefed. The powder is believed to be the seeds, which through a microscope appear of a spheroidal form, and to be annexed to elastic hairs.

LYCOPODIS, a genus of the monogynia order, in the pentadactyla class of plants, and in the natural method ranking under the 41st order, Asperifolia. The corolla has an incurved tube. There are eight species, chiefly annuals.

LYCOPODIS, a genus of the monogynia order, belonging to the diadactyla class of plants, and in the natural method ranking under the 42nd order, Cardiactylaceae. The corolla is quadrifid, with one of the segments reniform; the stamina standing asunder, with four free stamens. There are three species, of which the water-lehornes might probably be of use in dyeing.

LYCENUS, a genus of the monogynia order, in the dendraclava class of plants, and in the natural method ranking under the fourth order, Gramina. The spatha or sheath is monoplyphenous; there are two corola of the same genus; the nut is biliocular. There is one species, a grass of Spain.

LY DIAN STONE, in mineralogy, is commonly intersected by veins of quartz. Fracture even, and sometimes inclining to concave. Specific gravity, 2.96. Powdery, black, or greyish black. This stone, or one similar to it, was used by the Etruscans as a touchstone. They drew the metal to be examined along the stone, and judged of its purity by the colour of the streak. On this account it was called Bauxite, the Etruscan. It was called the Lydian stone, as being found in the river Molosius in Lydia.

LYMPH. See Anatomy, and Physiologist.

LYNX. See Felis.

LYRE, lyra, a musical instrument of the string kind, much used by the ancients.

LYRE, lyra, in astronomy, a constellation of the Lower hemisphere, the number of whose stars, in Ptolemy's and Tycho's catalogues, are only 10, but 19 in the British catalogue.

LYRIC. See Poetry.

LYSIMACHIA, Loosestrife, a genus of the monogynia order, in the pentadactyla class of plants, and in the natural method ranking under the 20th order, Rotenaceae. The corolla is rotund, the calyx, beaked. There are three species, but only four are commonly cultivated in gardens. These are hardy herbaceous perennials and biennials, rising with erect stalks from inches to two or three feet in height, and terminated by spikes and clusters of monopetalous, rosetted, five-petalled spreading flowers of white and yellow colours. The mugunmul, or yellow moneywort, or herb jevoperuse, is particularly beautiful.

LYTHRIUM, purple Loosestrife, a genus of the monogynia order, in the dendraclava class of plants, and in the natural method ranking under the 17th order, Calycanthaceae. The calyx is short, the corolla long, and there are six petals inserted into it; the capsule is biliocular and polyspernum. There are 18 species, of which the most remarkable is 1. The salicaria, or common purple Loosestrife, with oblong leaves, is a native of Britain, and grows very naturally by the sides of ditches and rivers. 2. The hispanus, or Spanish Loosestrife, with a hyssop leaf, grows naturally in Spain and Portugal. The flowers are larger than those of the common sort, and make a fine appearance in the month of July, when they are in beauty.
M. The twelfth letter of our alphabet. As a numeral it stands for mille, a thousand; and with a dash over it, thus M, for a thousand times a thousand, or 1,000,000. Used as an abbreviation M. signifies Marinus, Marcus, Maurus, Maximus; and M. and M. for manumitter bond; Mag. Eq. magister equitum; Mag. Ml. magister militum; M. M. P. magnum magnificat poestate; M. A. magister articulus; M. S. into subscript, and M. S. S. manuscripts, in the plural form the prescribers of physicians, M. stands for manipulus, a handful; and sometimes for missiles, or mixtura.

MAB, a genus of the triandria order, in the discus, or the stigmas, the perianthium of the male is triusth; that of the female is as in the male; the fruit is a plum two-celled, superior. There is one species, a tree of the Friendly Islands.

MACROLOBIUM, a genus of the monocotyledonous, or milk-seed family. The caryx is one-seeded; corolla none. There are two species, called plicepod, shrubs of the West Indies.

MACRONE, MACRONE, an application given to a horticultural kind of poetry, made up of a jumble of words of different languages, and words of the vulgar tongue Latinized.

MACRE, the second or covering of the kernel of the nutmeg, is a thing of the nutmeg and branched substance, of an ocelalous nature and a yellowish colour; being met with in flakes of an inch and more in length, which are divided, in a multitude of ramifications. It is of an extremely fragrant, aromatic, and agreeable flavour, and of a pleasant, but acid and ocealous taste. See MYRTICALE.

MACEANION, in pharmacy, is an infusion or soaking ingredients in water, or any other liquid, in order either to soften them, or draw out their virtues. MACHINE. See MECHANICS.

MACKREL. See SEAFISH.

MACROQUEL, a genus of the class and order pentandria monognay. The cor. is bell-shaped; the capsule two-celled, two-valved; seeds imbricate. There are three species, small trees of the West Indies.

MACULE, in astronomy, are dark spots appearing on the luminous surface of the sun. They are produced by the action of the sun on the outer parts of the sun, and are visible in the sun's disk. The solar maculae are dark spots of an irregular and changeable figure, observed in the face of the sun. These were first observed in November and December of the year 1610, by Galileo in Italy, and Hariot in England, unknown to, and independent of, each other, soon after they had made or procured telescopes.

There have been various observations made of the phenomena of the solar macule, and hypotheses invented for explaining them. Many of these macule appear to consist of heterogenous parts: the darker and denser being called, by Hevelius, nuclei, which are encompassed as it were with atmospheres, somewhat rarer and less obscure; but the figure, both of the nuclei and entire macule, is variable. These macule are often subject to sudden mutations. In 1644 Hevelius observed a small thin macule, which in two days time grew to ten times its bulk, appearing also much darker, and having a larger nucleus; the nucleus began to fail sensibly before the spot disappeared; and before it quite vanished, it broke into four, which resolved into many, but were not sensible upon the first appearance in the middle parts; that they contract themselves near the limb, and the middle appear larger; that they often run into one in the disc, though separated near the centre; that many of them first appear in the middle, and many disappear there; but that none of them deviate from their path near the horizon; whereas Hevelius, observing Mercury in the sun near the horizon, found him too low, being depressed 27° beneath his former path.

From these phenomena are collected the following consequences:

1. That since Mercury's depression below his path arises from his parallax, the macule having no parallax from the sun, are much nearer than that planet.

2. That since they rise and disappear again in the middle of the sun's disc, and undergo various alterations with regard both to bulk, figure, and density, they must be formed de novo, and again dissolved about the sun; and hence some have inferred, that they are a kind of solar clouds, formed out of his exhalations, and if so, the sun must have an atmosphere.

3. Since the spots appear to move very regularly about the sun, it is hence inferred, that it is not that they really move, but that the sun revolves round his axis, and the spots accompany him, in the space of 27 days, 12 hours, 20 minutes.

4. Since the sun appears with a circular disk in every situation, his figure, as to sense, must be spherical.

The magnitude of the surface of a spot may be estimated by the time of its transit over a hair in a fixed telescope. Galileo estimates some of the spots larger than both Asia and Africa put together; but if he had known more exactly the sun's parallax and distance, as they are known now, he would have found some of those spots much larger than the whole surface of the earth. For in 1612 he observed a spot so large, that it could be plainly visible to the naked eye, and therefore it subtended an angle of about a minute. But the earth, seen at the distance of the sun, would subtend an angle of only about 17'; therefore the diameter of the spot was to the diameter of the earth, as 102 to 17, or 33 to 1 nearly; and consequently the surface of the spot, if circular, to a great circle of the earth, as 124 to 1, and to the whole surface of the earth, as 124:4, or nearly 3 to 1. Gessendus observed a spot whose breadth was 96 of the sun's diameter, and which therefore subtended an angle at the eye of a navigator, a half, and consequently its surface was above seven times larger than the surface of the whole earth. He says he observed above 40 spots at a time, without being able to diminish the light of the sun.

In the year 1779 there was a spot on the sun which was large enough to be seen by the naked eye. It was divided into two parts, and must have been 300 miles in diameter. Various opinions have been advanced concerning the nature, origin, and situation of the solar spots; but the most probable seems to be that of Dr. Wilson, professor of practical astronomy in the university of Glasgow. By attending particularly to the different phases presented by the umbra, or shady zone, of a spot of an extraordinary size that appeared on the sun, in the month of November 1779, during its progress over the solar disc, Dr. Wilson was led to form a new and singular conjecture on the nature of these appearances; which he afterwards greatly strengthened by repeated observations. The results of these observations, it is the opinion of the sun is that the solar macule are cavities in the body of the sun; that the nucleus, as the middle or dark part has usually been called, is the bottom of the excavations; and that the umbra, or shady zone surrounding it, is the shadow sides of the cavity. Dr. Wilson, besides having satisfactorily ascertained the reality of these immense excavations in the body of the sun, has also pointed out a method of measuring the depth of them. He estimates, in particular, that the nucleus or bottom of the large spot above-mentioned, was not less than a semidiameter of the earth, or about 4000 miles below the level of the sun's surface, while its other dimensions were of a much larger extent. He observed that a spot near the middle of the sun's disc is surrounded equally on all sides with its umbra; but that when, by its apparent motion over the sun's disc, it comes near the western limb, that part of the umbra which is next the sun's centre gradually diminishes in breadth, till near the edge of the limb it totally disappears; whilst the umbra on the other side of it is little or nothing altered. After a semi-revolution of the sun on his axis, if the spot appear again, it will be on the opposite side of the disc, or on the left hand, and the part of the umbra which had before disappeared is now plainly to be seen; while the umbra on
the other side of the spot seems to have vanished in its turn, being hid from the view by the upper edge of the excavation, from the declivity of the mound, and its parts right with respect to the eye. But as the spot advances on the sun’s disc, this umbra, or side of the cavity, comes in sight; at first appearing narrow, but afterwards gradually increasing in breadth, as the spot moves towards the middle of the disc. These appearances perfectly agree with the phases that are exhibited by an excavation in a spherical body, revolving on its axis, the bottom of the cavity being painted black, and the sides lightly shaded.

Dr. Herschel supposes that the spots in the sun are mountains on its surface, which considering the great attraction exerted by the sun upon bodies placed at its distance, and the slow revolution it has about its axis, he thinks may be more than 300 miles high. He says, that in August 1797, he examined the sun with several powers, from 90 to 500, and found all the black spots are the opaque ground or body of the sun, and that the luminous part is an atmosphere which being broken, gives a glimpse of the sun itself.

MADDER. See RUBIA.

MADNESS. See MEDICINE.

MADREPORA, in natural history, the name of a genus of submarine substances; the character of which is, that they are almost of a stony hardness, resembling the coral, and are usually divided into branches, and pervious by many holes or cavities, which are frequently of a stellar figure.

In the Linnéan system, this is a genus of Lithophyta: the animal that inhabits it is called Madrepora. It comprehends 30 species. According to Donati, the madrepora is like the coral as to its hardness, which is equal to bone or marble; its colour is white when polished; its surface is slightly wrinkled, and the wrinkles run longitudinally of the branches; in the centre there is a sort of cylinder, which is often pierced through its whole length by two or three holes. From this cylinder are detached about 17 lamina, which run to the circumference directly in straight lines; and are transversely intersected by other lamina, forming many irregular cavities; the cells, which are composed of these lamina, range into a circle, are the habitations of little polypes, which are extremely tender animals, generally transparent, and variegated with beautiful colours.

M. de Puysson, observes, that those writers who only considered the figures of submarine substances, denominated that class of them which seemed pierced with holes, pera, and those the holes of which were large they called madrepora. He defines them to be all those marine bodies which are of a stony substance; but which have but one apparent opening at each extremity, furnished with rays that proceed from the centre to the circumference. He observes that the body of these kind of the madrepora, whose flesh is so soft that it divides upon the gentlest touch, fills the centre; the head is placed in the middle, and surrounded by several feet or claws, which fill the extremity of the partitioned observatory of this substance, and are at pleasure brought to the head, and are furnished with yellow papillae.

He discovered that its head or centre was lifted up occasionally above the surface, and often contracted and dilated itself, like the pupil of the eye, so as to all its claws moved, as well as its head or centre. When the animals of the madrepora are destroyed, its extremities become white. In the madrepora, he says, the surface of the cavity, and the substance is of a stony but more loose texture than the coral. This is formed, like other substances of the same nature, of a liquor which the animal discharges: and he further says that the specific species of the polype of the madrepora which are produced singly, and others in clusters. See Plate Nat. Hist. tigs. 239 and 237; and ZOOPHYTAE.

MADREPORITE, a mineral found in the valley of Russbach in Salzburg, and which obtained its name from its resemblance to madrepora. Colour in some parts black, in others dark grey. Found in large rounded masses. Fracture even to the conchoidal. Lustre greasy, passing to the silky. Brittle: moderately heavy. streak grey; it is composed of 93.00 carbonate of lime. 0.30 carbonate of magnesia. 7.65 carbonate of iron. 0.50 charcoal. 4.50 silica in sand.

99.75.

MADR, in the military art, a long and broad plank of wood, used for supporting the earth in mining and carrying on a sap, and in making coffers, caponiers, galleys, and for many other uses at a siege. Madriers are also used to cover the mouths of petards after they are loaded, and are fixed with the petards to the gates or other places designed to be forced open.

MEMACTERION, the fourth month of the Athenian year, consisting of only 29 days, and answering to the latter part of September and the beginning of October.

MAGAZINE, a place in which stores are kept, or arms, ammunition, provisions, &c. Every fortified town ought to be furnished with a large magazine, which should contain stores of all things requisite to enable the garrison and inhabitants to hold out a long siege, and in which smiths, carpenters, wheelwrights, bakers, &c. may be employed in making every thing belonging to the artillery, as carriages, wagons, &c.

MAGAZINE, powder, is that place where the powder is kept in very large quantities.

Authors differ greatly both in regard to situation and construction; but all agree, that it ought to be arched, and bomb-proof. In fortifications they are frequently placed in the rampart; but of late they have been built in different parts of the town. The first powder-magazines were made with Gothic arches; but M. Vauban, finding them too weak, constructed them in a semicircular form, whose dimensions are 60 feet long, within 25 broad; the foundations are eight or nine feet thick, and eight feet high from the foundation to the spring of the arch; the door is two feet from the ground, which keeps it from dampness.

One of our engineers of great experience, some time since observed, that after the centres of semicircular arches are struck, they settle at the crown, and rise up at the

menhurcs, even with a straight horizontal extrados; and still much more so in powder-magazines, where the top is formed like the roof of a house, by two inclined planes joining in an angle over the top of the arch, to give a proper descent to the rain; which effects are exactly what might be expected according to the true theory of arches. Now, as this shrinking of the arches must be attended with very ill consequences, by breaking the texture of the cement after it has been in some degree dried, and also by opening the joints of the masonry on one end, a remedy is provided for this inconvenience, with regard to bridges, by the arch of equilibriation in Dr. Hutton’s book on bridges; but as the ill effect is much greater in powder-magazines, the same ingenious gentleman proposed to find an arch of equilibriation for them also, and to construct it when the span is 20 feet, the pitch or height 10 (which are the same dimensions as the semicircle), the inclined exterior walls at top forming an angle of 113 degrees, and the height of their angular point above the top of the arch equal to seven feet.

MAG, or MAGIAN, an ancient religious sect in Persia, and other Eastern countries, who maintained, that there were two principles, the one the cause of all good, the other the cause of all evil; and abominating the erection of images, worshipped God only by fire, which they looked upon as the brightest and most glorious symbol of Ormades, or the good God: as darkness is the truest symbol of Ahriman, or the evil God. The sect still subsists in Persia, under the denomination of gauv.

MAGIC LANTERN. See OPTICS.

MAGIC SQUARE, in arithmetic, a square figure made up of numbers in arithmetic proportion, so disposed in parallel and equal ranks, that the sums of each row, taken either perpendicularly, horizontally, or diagonally, are equal: thus,

Natural square. Magic square.

1 7 3 1
2 5 9 2
3 1 7 3
4 5 9 4

5 4 3 5
6 1 9 6
7 9 1 7
8 2 3 8

Magic squares seem to have been so called, from their being used in the construction of talismans.

MAGNA CHARTA, the great charter of the liberties of England, and the basis of our laws and privileges.

This charter may be said to derive its origin from king Edward the Confessor, who granted several privileges to the church and state, by charter; these liberties and privileges were also granted and confirmed by king Henry I., by a celebrated great charter the abridgment of which was confirmed or reenacted by king Henry II. and king John. Henry III., the successor of this last prince, after having caused twelve men to make enquiry into the liberties of England in the reign of his predecessor, granted a new charter, which was the same as the present Magna Charta; this he several times confirmed, and as often broke; till in the thirty-seventh year of his reign, he went to Westminster-hall and there in presence of the clergy and bishops, who held lighted candles in their hands, Magna Charta was read, the king all
the while holding his hand to his breast, and at last solemnly swearing faithfully and
invocably to observe all the things therein contained, &c.; then the bishops extinguishing
the candles, and throwing them on the ground, cried out, "Thus let him be extin-
guished," and Thadd, who violates this charter." It is observed, that notwithstanding
the solemnity of this confirmation, king Henry, the very next year, again invaded
the rights of his people, till the barons entered into a war against him; but, after
various success, he confirmed this charter, and the charter of the forest, in the fifty-
second year of his reign. This excellent charter, of equitable and beneficial to the
subject, is as follows, viz.: by the 25 Edw. I. it is ordered, that it shall be taken as the common law;
and by the 41 Edw. III. all statutes made
against the liberties are declared void.

MAGNESIA. About the beginning of the eighteenth century, a Roman cannon was
exposed a white powder to sale at Rome as a cure for all diseases. This powder he
bought and kept; and by the manner of preparing it a profound secret; but in 1703
Valenții informed the public that it might be obtained by calcining the lithiwm which
remains after the preparation of nitre; and two years after, sticking in his discovery that
might be precipitated by potass from the mother-
llei of niter. This powder was generally
supposed to be fine, till Frederic Hoff-
man observed that it formed very different combinations with water. But little was
known concerning its nature, and it was even confounded with lime by most chemists, till
Dr. Black made his celebrated experi-
ments on it in 1773. Margarett published a disserta-
tion on it in the Philosophical Transactions, in
the 1773, in which he collected the observations of these two philosophers, and which he en-
riched also with many additions of his own. Bothi and Bergman published a valu-
able dissertation on it in 1773.

As magnesia has never yet been found native in a state of purity, it may be pre-
pared in the following manner: sulphat of magnesia is heated in a clay crucible, stained
the sulphuric acid, exists in sea-water, and in
many springs, particularly in some about Epsom; from which circumstance it was
formerly called Epsom salt. This salt is to be
dissolved in water, and half its weight of potas-
s oxide added. The magnesia is immediately
precipitated, because potass has a stronger
affinity for sulphuric acid. It is then to be
washed with a sufficient quantity of water
and dried.

Magnesia thus obtained is a very soft white powder, which has very little taste, and is
totally destitute of smell. Its specific gravity is about 2.3. It converts delicate vegetable
bodies (paper for instance, stained the petals of the mallow) to green.

It is not melted by the strongest heat to which it has been possible to apply; but M. Darct
observed that, in a high temperature, it becomes somewhat agglutinated. When
formed into a cake with water, and then exposed to a violent heat, the water is gradually
driven off, and the magnesia contracts in its dimension; at the same time, it acquires
the property of shining in the dark when rubbed upon a hot iron plate.

It is almost insoluble in water; for, ac-
cording to Mr. Kirwan, it requires 7900
times its weight of water at the temperature
of 60° to dissolve it. It is capable, however,
of combining with water in a solid state; for 100 parts of magnesia, thrown into water,
and then dried, are increased in weight to 111.5 parts. Even when combined with car-
bonic acid (for which it has a strong affinity) it is capable of absorbing and retaining 15
times its own weight of water without letting
it go a drop; but on exposure to the air, this
water evaporates, though more slowly than it would from lime.

Magnesia has never yet been obtained in a crystallized form.

When exposed to the air, it attracts carbo-
ic acid gas and water; but exceedingly
slowly. Buttin left a quantity of it for two
years in a porcelain cup mettely covered with
paper; its weight was only increased 1.47
part.

Magnesia does not combine with oxygen; nor is it altered by any of the compounds
into which oxygen enters. The only one of the simple combustibles with which it can
be united is sulphur. No person has hitherto
succeeded in forming a phosphuret of mag-
nesia. The sulphuret of magnesia may be
formed by exposing a mixture of two parts of magnesia and one part of sulphur, to a
light at a distance. The result is a yellow
powder, slightly agglutinated, which unites very little sulphuret hydrogen gas,
when thrown into water. A moderate heat
is sufficient to drive off the sulphur.

Magnesia does not combine with azote, but forms a yellow oxide. It also forms a
compound called muriat of magnesia. It has no action upon the meals; nor does it
combine, as far as is known at present, with the metallic oxides, unless some intermediate
substance is present. It does not combine with the fixed alkalis, neither are its proper-
ties altered by these bodies; but it has a strong propensity to enter into triple com-
positions with ammoniac.

It is capable of forming to little affinity between magnesia and barytes; at least no mixture
of the two earths is fusible in the strongest heat which it has been possible to apply.

Mr. Kirwan has shewn that there is but little affinity between strong magnesia and water.
They do not melt when exposed to a strong
heat, at least when the stroniant exceeds
or equals the magnesia.

Equal parts of lime and magnesia, mixed
together, and exposed by Lavassier to a
very violent heat, did not melt; neither did
they melt when Mr. Kirwan placed them in
the temperature of 130° Wedgewood.

The affinities of magnesia, according
to Borken, are as follows:

Magnesia is used in medicine, to remove
heavy affections.

MAGNETISM. The nature i magnet, or
loadstone, is a hard mineral body of a dark
brown, or almost black colour, and when
examined, is found to be an ore of iron. It is
met with in various countries, generally
in iron mines, and of all sizes and forms.

This singular substance was known to the
antients; and they had remarked its peculiar
property of attracting iron, though not appear
that they were acquainted with the wonderful property which it also has, of
returning to the pole when suspended, and left
at liberty to move freely.

Upon this remarkable circumstance the
mariners' compass depends, an instrument
which gives us such innumerate advantages over
the antients. It is this which enables the
mariners to conduct their vessels through
vast oceans out of the sight of land, in any
given direction; and this directive property
also guides the miners in their subterranean
excavations, and the traveller through de-
serts otherwise impassable.

It is not precisely known when and by
whom this directive property of the magnet
was discovered. The ancients and nearly all the accounts seem to prove, that it was
known early in the 13th century; and that the
person who first made mariner's compasses, at
least in Europe, was a Neapolitan of the
name of Friar, or John de Gugio, or Giusa,
or Giusa.

The natural loadstone has also the qua-
lity of communicating its properties to iron
and steel, when and on which it is placed and touched, as it is called, by the
loadstone, they are denominated artificial
magnets.

These artificial magnets are even capable of
being made more perfect than the na-
tural ones; and as they can be made of any
form, and are more convenient, they are
now universally used, so that the loadstone
or natural magnet is only kept as a curiosity.

All magnets, whether natural or artificial,
are distinguished from other bodies by the
following characteristics, which appear to be
inseparable from their nature; so that no
body can be called a magnet, unless it is
possessed of all these properties:

1. A magnet attracts iron.
2. When a magnet is placed so as to be
at liberty to move freely in every direction,
it's end points towards the poles of the earth,
which is generally, by very much more powerful than the
other.
3. When the north pole of one magnet
is presented to the south of another magnet,
these ends attract each other; but if the
south pole of one magnet is presented to the
north pole of another, or the south pole of
one to the north pole of another, these ends
will repel each other.

From these criteria, it is easy to determine
the names of the poles of a magnetic bar,
by applying it near a suspended magnet whose
poles are known.

4. When a magnet is situated so as to be
at liberty to move itself with sufficient free-
dom, its two poles do not lie in a horizontal
direction, but it generally inclines one of
them towards the horizon, and of course it
elevates the other pole above it. This is
Magnetism.

When a piece of iron is brought within a certain distance of a magnet, it becomes attracted, in fact, itself, having the polarity, the attractive and repulsive properties for other iron, &c.; that part of it which is nearest to the south pole of the magnet, becoming a north pole, and the opposite part a south pole, or vice versa, according to the end of the magnet presented. Thus if A B, Plate Magnetism, fig. 1, be an oblong piece of iron, and be brought near the north pole N of the magnet N S, then this piece of iron will be drawn towards the magnet while standing in the same position, will have all the properties of a real magnet, and its end A will be found to be a south pole, while the end B is a north pole.

Soft iron, when placed within the influence of a magnet, easily acquires these properties; but they last only while the iron remains in that situation, and when it is removed its magnetism vanishes immediately. But with iron containing carbon, and particularly with steel, the contrary holds, as the iron or the steel is, the more permanent is the magnetism which it acquires from the influence of a magnet; but it will be in the same proportion more difficult to render it magnetic, and therefore more easily to destroy it.

If a piece of soft iron, and a piece of hard steel, both of the same shape and size, are brought within the influence of a magnet at the same distance, it will be found that the soft iron is attracted more powerfully, and appears more powerfully magnetic, than the steel; but if the magnet is removed, the soft iron will instantly lose its acquired properties, whereas the hard steel will preserve them for a long time, having become an artificial magnet.

Neither the magnetic attraction nor repulsion is in the least diminished, or at all affected, by the interposition of any sort of bodies, except iron, or such bodies as contain iron.

The properties of the magnet are not affected either by the presence or by the absence of air. Heat weakens the power of a magnet, but the power of the heat, is not quite to its former degree. A white heat destroys it entirely, or very nearly so; and hence it appears, that the powers of magnets must be varying continually. C. Cavalli observed, that heat, either red or white heat, is not attracted by the magnet; but the attraction commences as soon as the redness begins to appear.

The attractive power of a magnet may be considerably improved by suspending a weight of iron to it by its power of attraction, which may be gradually increased; and also by keeping it in a proper situation, viz. with its north pole towards the north, and its south pole towards the south, and always keeping it in this situation. On the contrary, this power is diminished by an improper situation, and by keeping too small a piece of iron, or no iron at all, appended to it.

In these northern parts of the world, the north pole of a magnet has more power than its south pole; whereas, the contrary effect has been said to take place in the southern parts.

Amongst the natural magnets, the smallest generally possess a greater attractive power in proportion to their size than those of a larger size. It frequently happens, that a natural magnet, cut off from a larger lodestone, will be able to lift a greater weight of iron than the original lodestone itself.

As both magnetic poles together attract a much greater weight than a single pole; and as the two poles of a magnet generally are in opposite parts of its surface, in which case it is almost impossible to adapt the same piece of iron to both poles at the same time; therefore it has been commonly practised to adapt two broad pieces of soft iron to the poles of the stone, and to let them project on one side of the stone; for those pieces having the same poles be applied to and, and to the piece of iron or weight may be easily adapted. Those two pieces of iron are generally fastened upon the stone by means of a brass or silver box. The number is fixed, as it is said, by an art, and the two pieces of iron are called the armature.

Fig. 1 represents an armed magnet, where A B is the lodestone; C D, C D', are the armature, or the two pieces of soft iron, to the position of which, a D D', the iron weight F is applied. The dots E C D C D' represent the brass box, with a ring at E, by which the armed magnet may be suspended.

Artificial magnets, when straight, are sometimes armed in the same manner; but they are frequently made in the shape of a horse-shoe, having their poles at the truncated extremities, as at N and S, fig. 3, in which case it is evident that they want no armature.

Most probably the magnet attracts iron only; but when it is considered how universally iron is dispersed throughout nature, it is evident that a vast number of bodies must on that account be attracted by the magnet more or less forcibly, in proportion to the quantity and quality of the iron they contain; it is evidently to be observed, what a small portion of iron will render a body subject to the influence of the magnet.

The polarity of the magnet. — Every magnet has a south and a north pole, which are opposite to one another; one is called the north, and the other, the south; and we say that a magnet is polarised, when a north and a south pole are produced in it. The North is always directed towards the north, the South to the south, and can never be reversed; and it is the property of the magnet that renders it so useful to navigators. When a magnet is kept suspended freely, so that it may turn freely, a north and south pole, by looking at the position of it, can steer his course in any required direction. Thus, if a vessel steered towards a certain place which lies exactly westward of that from which it set out, the navigator must direct it to, that its course may be always at right angles with the direction of the magnetic needle of his compass, keeping the north end of the magnet on the right-hand side, and of course, the south end on the left-hand side of the vessel; for as the needle points north and south,
and the direction is east and west, the intended course of the vessel is exactly perpendicular to the direction of the needle. A little reflection will show how the vessel may be steered in any other direction.

An artificial magnet fitted up in a proper box, for the purpose of guiding the direction of a traveller, is called a magnetic needle, and the whole together is called the mariner's compass.

Although the north pole of the magnet in every part of the world, when suspended, points towards the poles of the earth, the south pole of the earth is not the north pole of the magnet, but the north pole of the magnet is the south pole of the earth. The angle in which it deviates from due north and south, is called the angle of declination, or the declination of the magnetic needle, or the variation of the compass; and this declination is said to be east or west, according as the north pole of the needle is eastward or westward of the extremities of the magnetic needle.

This deviation from the meridian is not the same in all parts of the world, but is different in different places, and it is even continually varying in the same place. For instance, it is not the same in London as at Paris, or as in India; and the declination in London, or in any other place, is not the same at this time as it was some years ago. This declination from the meridian is so various, that it may be said to change, even in one or two hours time: and this is not owing to the construction of the magnetic needle; for in the same place, and at the same time, all true magnetic needles point north and south in the same way.

The declination from the meridian, and the variation of this in different parts of the world, are very uncertain, and cannot be foretold; and this is the only method of ascertaining them. This circumstance forms a great impediment to the improvement of navigation. It is true, that great pains have been taken by navigators and other observers, to ascertain the declination in various parts of the world, and such declinations have been marked in maps, charts, books, &c.; but still, on account of the constant change to which this variation is liable, these can only serve to confirm the law of this variation or fluctuation being yet not determined, though various hypotheses have been formed for that purpose. When the variation was first observed, the north pole of the magnetic needle declined eastward of the meridian of London; but it has since that time been changing continually towards the west; so that in the year 1657 the magnetic needle pointed due north and south. At present, it declines and is towards the south, and it seems to be still advancing towards the west.

Before volcanic eruptions and earthquakes, the magnetic needle is often subject to very extraordinary perturbations. It is also agitated before and after the appearance of the aurora borealis.

The magnetic inclination, or dip of the needle.—If a needle which is accurately balanced, and suspended so as to turn freely in a vertical plane, in a horizontal plane, the north pole will be depressed, and the south pole elevated above the horizon: this property is called the inclination, or dip of the needle, and was discovered by Robert Norman, about the year 1739.

Take a globular magnet, or, which is more easily procured, an oblong one, like 8 N, fig. 4; the extremity N of which is the north pole, or the dipole of the magnet, and A its middle or equator; place it horizontally upon a table C D; then take another small oblong magnet u s (viz. a bit of steel wire, or a small sawing-needle magnetized), and suspend it by means of a fine thread tied to its middle, so as to remain in an horizontal position, when not disturbed by the vicinity of iron, or other magnet. Now if the same small magnet, being held by the upper part suspended at a distance from the middle of the large magnet, will be found to be inclined in the same manner to its middle, so as to remain in an horizontal position, without being disturbed by the vicinity of iron, or other magnet. Now if the same small magnet, being held by the upper part suspended at a distance from the middle of the large magnet, will be found to be inclined in the same manner to its middle, so as to remain in an horizontal position, without being disturbed by the vicinity of iron, or other magnet.

If the geographical poles of the earth (that is, the ends of its axis), coincided with its magnetic poles; or even if the magnetic poles were constantly at the same distance from them; the inclination of the needle, as well as its declination, would always be the same; and hence, by observing the direction of the magnetic needle in any particular place, the latitude and longitude of that place might be ascertained; but this is not the case, for the magnetic poles of the earth do not coincide with its real poles, and they are also constantly shifting their situation; hence the magnetic needle changes continually, not only in its horizontal direction, but likewise in its inclination, according as it is removed from one place to another, and also while it remains in the very same place.

This change of the dip in the same place, however, is very small. In London, about 1576, the north pole of the dipping needle stood 7° 50′ below the horizon; and in 1753, it stood at 7° 3′; the whole change of inclination, during so many years, amounted to less than a quarter of a degree.

There are various methods of giving the magnetic property to steel or iron. In some cases, it appears to be acquired without the use of any magnets.

If you take a bar of iron three or four feet long, and hold it in a vertical position, you will find that the bar is magnetic, and will act upon another magnet; the lower extremity of the bar attracting the south pole, and repelling the north pole. If you invert the bar, the polarity will be instantly reversed; the extremity which is now lower, will be found to be a north pole, and the other extremity will be a south pole. A bar of hard iron, or steel, will not answer for the above experiment, the magnetism of the earth not being sufficient to magnetic it.

Bars of iron that have stood in a perpendicular position, are generally found to be magnetic; as fire-irons, bars of windows, &c.

If a long piece of hard iron is made red-hot, and then left to cool in the direction of the magnetic line, it becomes magnetic.

Striking an iron bar with a hammer, or rubbing it with a file, while held in this direction, likewise renders it magnetic. And electric shock produces the same effect; and lightning often renders iron magnetic.

A magnet cannot communicate a degree of magnetism stronger than that which itself possesses; but two or more magnets, joined together, may communicate a greater power to a piece of steel, than either of them possesses singly: hence we have a method of constructing very powerful magnets, by first constructing, during magnetic needles, and then joining them together to form a compound magnet, and to act more powerfully upon a piece of steel.

1. Place two magnetic bars, A, B, fig. 5, in a line with the north, or marked end of one, opposed to the south, or unmarked end of the other; but at such a distance from each other, that the magnet to be touched may rest with its marked end on the unmarked end of the other.
end of A, and its unmarked end on the marked end of B; then apply the north end of the magnet E, and the south end of D, to the middle of the bar C, which is intended to be raised as in the figure: draw E and D asunder along the bar C, one towards A, the other towards B, preserving the same elevation; remove E and D a foot or two from the bar C, and raise it off the ends, then bring the north and south poles of these magnets together, and apply them again to the middle of the bar C as before; repeat the same process five or six times, then turn the bar, and apply the opposite surfaces in the same manner, and afterwards the two remaining surfaces; by this means the bar will acquire a strong fixed magnetism.

2. Place the two bars which are to be touched to each other; and unite the ends by two pieces of soft iron, called supporters, in order to preserve, during the operation, the circulation of the magnetic matter: the bars are to be placed so that the marked ends (fig. 6), may be opposite the unmarked end B; then place the two attracting poles G and I on the middle of one of the bars to be touched, raising the ends, so that the bars may form an angle of two or three degrees; the ends G and I of the bars are to be separated two or three tenths of an inch from each other. Keeping the bars in this position, move them slowly over the bar A B, iron to end to the other, going end to end, and about fifteen times. Having done this, the poles of the bars (i.e. the marked end of one is always to be against the unmarked end of the other), are removed by the operation on the bar CD, and then on the opposite faces of the bars. The touch thus communicated may be further increased, by rubbing the different faces of the bars with sets of magnetic bars, displayed as in fig. 7.

In these operations all the pieces should be well polished, the sides and ends made quite flat, and the angles quite square. A magnet bent so that the two ends almost meet forms a horseshoe magnet, fig. 3.

To render it magnetic, place a pair of magnetic bars against the ends of the horse-shoe, with the south end of the bar against that of the horse-shoe, and the north end towards the north end of the bar to which is to be the south; the contact or lifter of soft iron, to be placed at the other end of the bars. Also rub the surfaces of the horse-shoe with a pair of bars placed in the form of a compass, or with another horseshoe magnet, turning the poles properly to the poles of the horse-shoe magnet; being careful that these bars never touch the ends of the straight bars. If the bars are separated suddenly from the horse-shoe magnet, its force will be considerably diminished; to prevent this, slip on the lifter, or support, to the end of the horse-shoe magnet, but touching the sides; otherwise, that it may not touch the bars; the bars may then be taken away, and the support slid to its place.

Magnetism is best communicated to compass needles by the following method: Prepare a pair of magnetic bars, not less than six inches in length. Fasten the needle down on a board, and with a magnet in each hand draw them from the centre upon the needle outwards; then raise the bars to a considerable distance from the needle, and bring them perpendicularly down upon the centre, and draw them over again. This operation repeated five or six times will magnetize the needle, and its ends will point to the poles contrary to those that touched them.

Over one end of a combined horse-shoe magnet, of at least two in number, and six inches in length, draw from its centre that half of the needle which is to have the contrary pole to the end of the magnet; raise the needle to a considerable distance, and draw it over the surface of the end about twenty times at least, and the same for the other half, will sufficiently communicate the power.

A set of bars are exceedingly useful for magnetizing other bars, or needles of compasses, &c. their power may also be increased when lost or impaired by mismanagement, &c. A set of such bars, viz. six bars and the two iron conductors, may be put in a box, taking care to place the north pole of one contiguous to the south pole of the next, and that contiguous to the north pole of the third, &c. as shewn in fig. 8. After which, if we need not describe how a knife, or any piece of steel, &c. may be rendered magnetic, or in what manner a weak magnet may be rendered more powerful. But it may perhaps be necessary to say something concerning the communication of magnetism to crooked bars like A B C, fig. 9.

Place the crooked bar flat upon a table, and to its extremities apply the magnetic bars curving after the magnetism, with the conductor or piece of soft iron F G; then to its middle apply the magnetic bars placed at an angle: or you may use two bars only, placed as shewn in fig. 9, and stroke the crooked bar with them from end to end, following the direction of that bent bar; so that on one side of it the magnetic bars may stand in the direction of the dotted representation I K. In this manner, when the steel A B C has been rubbed a sufficient number of times on one side, it must be turned with the other side upwards; &c.

In communicating magnetism, it is best to use weak magnets, and more that are stronger afterwards; but you must be very careful not to use weak after strong magnets. A magnet loses nothing of its own power by communicating to other substances, but is rather improved.

Every kind of violent percussion weakens the power of a magnet. A strong magnet has been entirely deprived of its virtue, by receiving several smart strokes of a hammer; but whatever damages or distorts the internal pares of a magnet will injure its magnetic force.

Fill a small dry glass tube with iron filings, press them in rather close, and then touch the tube as iron may be made into a bar, and the tube will attract a light needle; shake the tube, so that the situation of the filings may be disturbed, and the magnetic virtue will vanish. Magnets should never be handled with their north or south poles together; for when they are thus placed, they diminish and destroy each other's power. Magnetic bars should therefore be always left with the opposite poles laid against each other, or by connecting their opposite poles by a bar of iron. The power of a magnet is increased by letting a piece of iron remain attached to one or both of its poles, A, since magnetism should therefore be applied to both.

The difference of steel in receiving magnetism is very great, as is easily proved by touching in the same manner, and with the same number of strokes, two pieces of similar size, but of different kinds. With some sorts of steel, a few strokes are sufficient to impart to them all the power they are capable of receiving; other sorts require a longer operation; sometimes the magnet again; this renders them more than a small degree of magnetism.

A piece of spring-tempered steel will not retain as much magnetism as hard steel; soft steel, if hot, but those which are used for observing the daily variation, are made a little longer, and their extremities point the variation upon an arch or circle properly divided and allayed to the box.

The best shape of a magnetic needle is represented in figs. 10 and 11; the first of which shews the upper side, and the second shews a lateral view of the needle, which is of steel, having a pretty large hole in the middle, to which a conical piece of an iron or steel, adapted by means of a brass piece O, into which the agate-cap (as it is called) is fastened. Then the apex of this hollow cap rests upon the point of a pin P, which is fixed in the centre of the box, and upon which the needle, being properly balanced, turns very nimbly. For common purposes, these needles have a conical perforation made in the steel itself, or in a piece of brass which is fastened to the middle of the needle.

A mariner's compass, or compass generally used on board of ships, is represented in fig. 12. The box, which contains the card or compass, needle, is circular in form, and either of wood, or brass, or copper. It is suspended within a square wooden box, by means of two concentric circles, called gimbalbs, so fixed by cross axes a n, n, to the two boxes (see the plan, fig. 13), that the inner one, or compass-box, shall retain a horizontal position in all motions of the ship, whilst the outer or square box is fixed with respect to the ship. The compass box is covered with a pane of glass, in order that the motion of the card may not be disturbed by the wind. What is called the
MAG

MAG

MAG

in the magnetic line. The degrees of inclination are shown upon a divided circle, in the centre of which the needle is suspended. Fig. 10 represents a dipping-needle of the simplest construction. A B is the needle, the axis of which F E is secured upon the middle of two lateral bars C D, C D, which are made fast to the frame that contains the divided circle A B K. This machine is fixed on a stand G; but, when used at sea, it is suspended by a ring H, so as to hang perpendicularly. When the instrument is furnished with a stand, a spirit-level G is generally annexed to it, and the stand has three screws, by which the instrument is situated so that the centre of motion of the needle, and the division of 90° on the lower part of the divided circle, may be exactly in the same line, perpendicular to the horizon. See L M N.

The first experiments which follow, are principally intended to illustrate the theory.

Ex. 1. The method of discovering whether a body is attractable by the magnet or not, and whether it has any polarity or not, or which is its south, and which its north pole, is so easily performed by a few words; for by approaching an object to the body in question (which, if necessary, may be set to swim upon water), or by presenting the body in question to either extremity of a suspended magnetic needle, the desired object may be obtained.

Ex. 2. Tie two pieces of soft iron wire, A B, A B, fig. 17 and 18, each to a separate thread, A C, A C, which join at top, and forming them into a loop, suspend them so as to hang perpendicularly in the marked end D fig. 19, which is the north pole of a magnetic bar just under them, and the wires will immediately repel each other, as shown in fig. 19; and this divergency will increase to a certain limit, according as the magnet is brought nearer, and vice versa. The reason of this phenomenon is, that by the action of the north magnetic pole D, both the extremities B, B, of the wires, acquire the same direction, which causes the wires to repel each other; and the extremities, A, A, acquire the north polarity, in consequence of which they also repel each other.

If instead of the north pole D, you present the south pole of the magnetic bar, the repulsion will take place as before; but now the extremities B, B, acquire the north, and the extremities A, A, acquire the south polarity.

On removing the magnet, the wires, if of soft iron, will soon collapse, having lost all their magnetic power; but if steel wires, or common sewing-needles be used, they will continue to repel each other after the removal of the magnet; the magnetic power being retained by steel.

Ex. 3. Lay a sheet of paper flat upon a table, strew some iron filings upon it, place a small magnet among them; then give a few gentle shocks to the table, so as to shake the filings, and observe that they dispose themselves about the magnet N S, as shown in fig. 20; the particles of iron clunging to one another, and forming themselves into lines, which at the very poles N S, are in the same direction, and in the middle area of the magnet; a little sideways of the poles they begin to bend, and then they form complete arches, reaching from some point in the northern half of the magnet, to some other point in the southern half.

Ex. 4. Place a magnetic bar A B, fig. 21, and that one of its poles may project a short way beyond the table, and weigh it down, or lay weights upon it to make its weight C to it; then take another magnetic bar, D E, like the former, and bring it parallel to, and just over the other, at a little distance, and with the contrary poles towards each other; in consequence of which the attraction of B will be diminished, and the iron C, if sufficiently heavy, will drop off, the magnet A B being then only able to support a smaller piece of iron. By bringing the magnets still nearer to each other, the attraction of B will be diminished still farther; and, when the two magnets come quite into contact (provided they are equal in power), the attraction between B and C will vanish entirely.

MAGNETIC TE, whatever be the number of parts locally extended, or that has several dimensions; as a line, surface, solid, etc. The apparent magnitude of a body is that which is measured by the visual angle, formed by rays drawn from its extremities to the eye; so that whatever things are seen under the same or equal angles, appear equal, and vice versa.

MAGNOLIA, a genus of the polygynous order, belonging to the polyandrous class of plants; and in the natural method ranking under the 22d order, coniferae. The calyx is triplicate; there are nine petals; the capsules bilabed and imbricated; the seeds pendulous, and in the form of a berry.

There are seven species: the principal are,

1. The glaucus, or small magnolia, a native of Virginia, Carolina, and other parts of North America; it most places it rises from seven or eight to fifteen or sixteen feet high, with a slender stem. The wood is white and spongy, the flowers are produced at the extremities of the branches, are white, composed of six compound petals, and have an agreeable scent. 2. The grandiflora, or great magnolia, is a native of Florida and South Carolina. It rises, to the height of eighty feet or more, with a straight trunk upwards of two feet diameter, leaving a regular head. The leaves resemble those of the laurel, but are larger, and continue green throughout the year. The flowers are produced at the ends of the branches, and are of a purple-white colour. 3. The tripetala, or umbrella tree, is a native of Carolina; it rises, with a slender trunk, to the height of sixteen or twenty feet; the wood is soft and spongy; the leaves remarkably large, and composed of circular circles, somewhat resembling an umbrella, whence the inhabitants of those countries have given it this name. The flowers are composed of ten or twelve white petals, that hang down without any order. The leaves drop off at the beginning of winter. 4. The acuminate, with oval, spear-shaped, pointed leaves, is a native of the inland parts of North America. The leaves are near eight inches long, and five broad, ending in a point. The flowers come out early in the spring, and are composed of twelve white.
The seeds are sown in the spring and the plants are harvested in the fall. The crystals formed are then harvested and dried in the sun. The dried crystals are then ground into a fine powder, which is ready for use in gardens and parks.

Malachite is a green copper carbonate mineral that is often used in gardens as a natural fertilizer. It is a popular choice for gardeners because it is easy to grow and is safe for plants. It is also known for its unique crystal formation, which makes it a popular choice for collectors.

The active ingredient in malachite is copper carbonate, which is a natural source of copper. Copper is an essential nutrient for plants, as it is necessary for the production of chlorophyll, which is essential for photosynthesis.

Method of Preparation

1. Choose a spot in your garden where you want to use the malachite. This could be a garden bed, a flowerbed, or a rock garden.

2. Ensure that the soil in the area is well-drained and enriched with organic matter. This will help the malachite to break down and release its nutrients more effectively.

3. Mix the malachite powder with water to create a slurry. This will help to distribute the nutrient across the soil.

4. Apply the slurry to the soil, making sure to cover the entire area you want to fertilize.

5. Water the area after applying the slurry to help the nutrients to be absorbed by the plants.

6. Repeat this process every few weeks to ensure that the plants receive a consistent supply of nutrients.

Benefits of Malachite Fertilizer

- Malachite is a natural source of copper, which is essential for plant growth.
- It helps to improve soil structure and fertility.
- It is safe for use around plants and flowers.
- It is a good choice for gardeners who prefer to use organic fertilizers.

Potential Side Effects

- Malachite can be toxic to some plants, so it is important to use it with caution.
- It may also be harmful to pets and children if left in an accessible area.

Conclusion

Malachite is a popular choice for gardeners looking for a natural fertilizer. It is easy to grow and is safe for plants. With its unique crystal formation, it is also a popular choice for collectors. However, it is important to use it with caution and to follow the appropriate safety guidelines to ensure that it is used effectively and safely.
This acid bears a strong resemblance to the citric, but differs from it in the following particulars: 1. The citric acid shoots into fine crystals, but this acid does not crystallize. 2. The salt formed by the citric acid with lime is almost insoluble in boiling water; whereas the salt made with mallee acid and the same basis is readily soluble by boiling water. 3. Malic acid precipitates mercury, lead, and silver, from the nitrous base, and by a dissolu-
tion of gold when diluted with water; whereas citric acid does not alter any of these solutions. 4. Malic acid seems to have a less affinity than citric acid for lime; for when a solution of lime in the form of a boiler, with a salt formed from volatil'e alkali and citric acid, a decomposition takes place, and the latter acid combines with the lime, and is precipitated.

MALABLE, a property of metals, whereby they are capable of being extended under the hammer.

MALOE, a genus of the class and order monadophila polyanthia. The calyx is double, outer three-leaved; arils glomerate, one-seeded. There are two species, herbs of Tuscany, Italy.

MALPIGHIUS, Barbadhes cherry, a genus of the trigonia order, in the decandala class of plants, and in the natural method ranking under the fam. Trigoniaceae, the calyx is pentalophous, with deltiform pores on the outside at the base. There are five petals, roundish and unguculated; the berry unilocular and spermospermous. There are 18 species, all of them shrubbery of the warm and hot regions of America, rising with branchy stems from 8 to 10 feet high, ornamented with oval and lanceolate entire leaves, and large pentalophous flowers, succeeded by red, cherry-shaped, edible berries, with an acid and palatable flavour; and which in the West Indies, where they grow naturally, are used instead of cherries. Three of the species are reared in our gardens, and form a nice variety in the stove. They retain their foliage throughout the year; and begin to flower about the end of autumn, continuing in constant succession till the spring; after which they frequently produce and ripen their fruit, which commonly equals the size of a cherry. The flowers are of a pale-red or purple colour.

MALT, barley prepared, to fit it for making a potable liquor called beer, or ale, by stopping it short at the beginning of vegetation.

In making malt from barley, the usual method is to steep the grain in a sufficient quantity of water, for two or three days, till it swells, becomes plump, somewhat tender, and tinges the water of a brownish, or reddish-brown. Then this water being drain-
ed away, the barley is removed being drained away, the barley is removed and left to steep in cold water, from 7 to 10 feet; the temperature of the water being kept at the boiling point, the malt tea spontaneously heats, and begins to grow, shooting out first the radicle; and if continued, continues, then the palum, spire, or blade. But the proper stoppage short at the eruption of the radicle, otherwise the barley would be spoiled. In order to stop it, they spread the wet cloth thus over a large floor, and keep turning it once in four or five hours, for the space of two days, laying it somewhat thickly each time. After this, it is again thrown into a large heap, and there suffered to grow sensibly hot to the hand, as it would usually in 24 hours; then, being spread again, and cooled, it is thrown upon the kiln, to be dried crisp without scorching.

MALVA, kni-ghts of, otherwise called hospitale of St. John of Jerusalem, a religious and military residence is in the island of Malta. The order consists of three estates, the knights, chaplains, and ser-

vants at arms; there are also priests of the churches, friars-servants who as-

sist at the offices, and donnes or demiceross; but these are not reckoned constituent parts of the body: the government of the order is mixt, being partly monarchical, and partly aristocratic; the grand master is sovereign.

The knights forming this order consisted of eight different languages, but between the English having withdrawn themselves. None are admitted into this order but such as are of noble birth: the knights are of two sorts, the one, who are not fit to be candidates for the dignity of grand master, and grand-crosses, and those who are only knights as-

sistants; they never marry. The 'knights are received into this order, either by under-

taking the oaths prescribed by statutes, or by dispensation.

MALTHA, in antiquity, a kind of ce-

ment of which there were two sorts, native and factitious; one of the latter sort, much in use, consisted of pitch, wax, plaster, and gum. Another kind used by the Romans in their aqueducts, was made of lime slaked in wine, incorporated with melted pitch, and fresh fire. Natural maltha is a kind of bitu-

men, with which the Atlantics plaster their walls; and which being once set on fire, makes it burn more fiercely. See Bitumen.

MALVA, the mallow, a genus of the po-

yanthia order, in the monadophila class of plants, and in the natural method ranking under the 37th order, columnare. The calyx is double; the exterior one triphylous; the aril truncate, or oblong, with spermospermous. There are 34 species, consisting of herbaceous perennial, biennials, and annuals, for medical, economical, and ornamental uses. The leaves of the common mallow are reckoned the first of the four essential herbs; they were formerly in some esteem as food; at present decompositions of them are sometimes employed in dysenteries, heat, and sharpness of urine, and in general for obtaining acrimonious humours; their prin-
cipal use is in collicit glutyns, cataplasmata, and fonamentata. The leaves enter the official decocction for glutyns, and a conserve prepared from them. Several pieces of malva, macerated like herb, afford a thread superior to hemp for spinning, and which is said to make more beautiful cloths and stuff than even flax. These species are in Europe, and are called Atriplex; from the former, which affords stronger and longer fibres, cords and twine have also been made. From the native likewise a new sort of paper has been fabricated by M. de l'Ise.

MANATEE, in anatomy, the breasts of a female.

MAMMALIA, in natural history, the first class of animals in the Linnaean system, divided into seven orders. See Mammalia.

MAMMILLARY, See Anatomy.

MANATI, in zoology. See Trichekus.

MANCA, was a square piece of gold coin, commonly valued at 30 pence; and mancusa was as much as a bank of silver, having the name from muncu cussa, being coined with the hand (Leg. Cannt.). But the manca and mancusa were not always of that value; for sometimes the former was valued at six shil-

lings, and the latter at two.

MANDAMUS, is a writ issuing in the king's name out of the court of king's bench, and directed to any person, corporation, or inferior court of judicature commanding to some particular thing thereto specified, as appointing to their office and duty.

A writ of mandamus is a high prerogative writ of, on a most extensive remedial nature, and may be issued to a judge within their own jurisdiction, and to compel them to execute their jurisdiction, whether such jurisdiction arises from a mod-

ern charter, subsists by custom, or it is created by act of parliament, yet being in sub-

sidium, has of late been exercised in a variety of instances.

Mandamus was also a writ that lay after the year and a day (where, in the meantime, the writ called the donum extremum had not been sent out) to the escheator, commanding him to enquire of what lands held by

knight-service the tenant died seized, &c.

MANIPUS, was also a writ to charge the

sheriff to take into the king's hands all the lands and tenements of the king's widow, who, against her oath formerly given, mar-

ries without the king's consent. See Reg. 592.

MANNA, a genus of the class and order tetractria monogynia. The calyx is eight-leaved; corolla four-clit; capsule inferior, two-valved, one-celled; seeds imbric-

ate, unilocular. There are three species, apart of the West Indies.

MANGANESE. 1. The dark-grey or brown mineral called manganese has been long known and used in the manufacture of glass. A mine of it was discovered in England by Mr. Boyle. A few experiments were made upon this mineral by Glauber in 1659,
and by Waitz in 1785; but chemists in general seem to have paid but very little attention to it. The greater number of mineralogists, though much puzzled what to make of it, agreed in placing it among iron ores: but Pott, who published the first chemical examination of this mineral in 1740, has succeeded in that it contains scarcely any iron, Cronstedt, in his System of Mineralogy, which appeared in 1782, assigned it a place of its own, on the supposition that it consisted chiefly of a peculiar earth. Linnan examined it anew in 1763; and in the year 1768, which appears in the Viennese set of oxide experiments, in order to prove that a peculiar metal might be extracted from it. The same idea had struck Bergman about the same time, and induced him to request of Scheele, in 1771, to procure a sample of manganese. Scheele's dissertation on it, which appeared in 1774, is a masterpiece of analysis, and contains some of the most important discoveries of modern chemistry. Bergman himself published a dissertation on it the same year; in which he demonstrates that the mineral, then called manganese, is a metallic oxide. He accordingly made several attempts to reduce it, but without success; the whole mass either forming the form of scoria, or yielding only small separate globules attracted by the magnet. This difficulty of fusion led him to suspect that the metal was in quest of a strong analogy to platinum or gold, and at that time Dr. Gallus, who was making experiments on the same mineral, actually succeeded in reducing it by the following process: he fused a crucible with charcoal-powder well moistened with water, put into it some of the mineral formed into a ball by means of oil, then filled up the crucible with charcoal-powder, heated another crucible over it, and exposed the whole for about an hour to a very high heat. At the bottom of the crucible was found a metallic button, or rather a number of small metallic globules, equal in weight to one-third of the mineral employed. It is easy to see by what means this reduction was accomplished: the charcoal-powder separated the oxygen from the oxide, and the metal remained behind. The metal obtained, which is called manganese, was farther examined by Ihleman in 1782, Hielm in 1785, and Bind-bergen in 1788 and 1789.

Manganese, when pure, is of a greenish-white colour, and has a good deal of brilliancy. Its texture is granular. It has neither taste nor smell. Its hardness is equal to that of iron. Its specific gravity is 7.000. It is very brittle; of course it can neither be hammered, nor drawn out into wire. Its tenacity is unknown. It requires, according to Morvey, the temperature of 160° Wedgewood, and by Pott, 177°; so that, platinum excepted, it is the most infusible of all the metals. When reduced to powder it is attracted by the magnet, owing probably to a small portion of iron from which it can with difficulty be parted.

II. Manganese, when exposed to the air, attracts oxygen more rapidly than any other body, phosphorus excepted. It loses its lustre almost instantly, becomes grey, violet, brown, and at last black. These changes take place still more rapidly if the metal is heated in an open vessel.

This metal seems capable of combining with three different proportions of oxygen, and of forming three different oxides, the white, the red, and the black.

The protoxide or white oxide may be obtained by dissolving the black oxide of manganese in nitric acid by adding a little sugar. The sugar attracts oxygen from the black oxide, and converts it into the white, which is dissolved by the acid. Into the solution pour a quantity of potash; the protoxide precipitates in the form of a white powder. It is composed, according to Bergman, of 80 parts of manganese and 20 of oxygen. When exposed to the air it soon attracts oxygen, and is converted into the black oxide.

The deutoxide or red oxide may be obtained by dissolving the black oxide in sulphuric acid, without the addition of any combustible substance. When black oxide of manganese is dissolved in sulphuric acid, is heated in a retort, a great quantity of oxygen gas comes over, while the oxide, thus deprived of part of its oxygen, dissolves in the acid. Distil to dryness, and pour water over it, and filter. A red-coloured solution is obtained, consisting of the sulphate of manganese dissolved in water. On the addition of an alkali a red substance precipitates, which is the red oxide of manganese. According to Bergman it is composed of 74 parts of manganese and 26 of oxygen. This oxide likewise attracts oxygen when exposed to the atmosphere, and is converted into the black oxide.

The peroxide of black oxide of manganese exists abundantly in nature; indeed it is almost always in this state that manganese is found. It has been observed that the apellation manganese itself was originally applied. It may be formed very soon by exposing the metal to the air. This oxide, according to Fourcroy, is composed of 60 parts of manganese and 40 of oxygen. When heated to redness in an earthen retort it gives out abundance of oxygen gas, which may be collected in proper vessels. By this operation it is reduced nearly to the state of red oxide, but it is exposed to the air, and more or less oxidised. Occasionally, it absorbs a new dose of oxygen; and thus the same process may again be repeated. No oxygen gas can be obtained from the white oxide; a proof that its oxygen is ten is retained. A larger affinity than any other body is by the addition of oxygen which constitutes the black oxide. Seguin has observed, that in some cases the black oxide of manganese emits, before it becomes red, a quantity of azotic gas. When long exposed to a strong heat it assumes a green colour. In that state it is whitened by sulphuric acid, but not dissolved. A very violent heat fuses this oxide, and converts it into a green-coloured glass.

III. Manganese does not combine with hydrogen. When dissolved in sulphuric acid a black spongy mass of carburet of iron is left behind. Hence it has been supposed capable of combining with carbon; but it is more probable that the carbon is combined with the iron, which is almost always present in manganese. It seems pretty clear, however, that carburet of iron is capable of combining with this metal, and that it always forms a part of steel.

Bergman did not succeed in his attempt to combine manganese with sulphur; but he formed a sulphureted oxide of manganese, by combining eight parts of the black oxide with three parts of sulphur. It is of a green colour, and gives out sulphureted hydrogen when acted on by a fluid. It cannot be doubted, however, that sulphur is capable of combining with manganese; for Frois has found native sulphur of manganese in that ore of tellurium which is known by the name of orde of Nagrope.

Phosphorus may be combined with manganese by melting together equal parts of the metal and of phosphoric glass; or by dropping phosphorus upon red-hot manganese. The phosphure of manganese is of a white colour, brittle, granulated, disposed to crystallize, not altered by exposure to the air, and more fusible than manganese. When heated the phosphorus burns, and the metal is oxidized.

IV. Manganese does not combine with either of the simple combustibles.

V. Manganese combines with many of the metals, and forms with them alloys which have been but very imperfectly examined.

It unites readily with copper. The compound, according to Bergman, is very malleable, its colour is red, and it sometimes becomes green by age. Grelin made a number of experiments to ascertain whether this alloy could be formed by fusing the black oxide of manganese along with copper. He partly succeeded, and proposed to substitute this alloy instead of the copper of arsenic, which is used in the arts.

It combines readily with iron; indeed it has scarcely ever been found quite free: from some mixture of that metal. Manganese gives iron a white colour, and renders it hard. It combines also with tin, but scarcely with zinc.

It does not combine with mercury nor with bismuth. Grelin found that manganese cannot be alloyed with bismuth without great difficulty; and that it unites to antimony very imperfectly. Chemists have not attempted to combine it with gold, platinum, silver, nickel, nor cobalt.

VI. The affinities of manganese, and of its white and red oxides, are, according to Bergman, as follows:

MANGIFERA, the mango-tree, a genus of the monegynia order, in the pentandria class of plants, and in the natural method ranking with those of which the order is doubtful. The corolla is pentapetalous; the plum kidney-shaped. There are three species, the principal of which is a native of many parts of the East Indies, whence it has been transplanted to Brazil, and other warm parts of America. It grows to a large size.
the wood is brittle; the bark tough when old; the leaves are seven or eight inches long, and more than two inches broad. The flowers are produced in loose panicles at the ends of the branches, and are succeeded by large oblong kidney-shaped plums. This fruit, which is a long and slender thorn; the stem is small; the thorn narrow; the whole body, except beneath, covered with broad, but sharp-pointed, scales, which are straited throughout their whole length: the tail is more than twice the length of the body, and tapers gradually to the tip. The legs are very short, scaled like the body, and on each of the feet are four claws, of which those on the fore feet are stronger than those of the hind. The colour of the whole animal is dark brown, with a cast of yel-

lowish, and with a glossy or polished surface.

The manis tetradactyla grows to the length of five feet, measuring from the tip of the nose to the extremity of the tail.

2. Manis, a genus of quadrupeds of the order of bony animals, with slaty, or greyish, or greyish-brown, or very dark brown, or black, or very dark yellow, or yellow, or a kind of yellowish brown, tongue cylindrical and extended; mouth narrowed into a snout; body covered with scales. The genus manis presents an appearance not less extraordinary than that of the genera or amamiola; being covered on every part, except on the belly, with extremely strong and large homy scales, constituting a suit of armour still more powerful than in the following genus, and capable of defending the animals, when rolled up, from the assaults of the most fierce enemies. This external covering, together with the uncommon length of the body and tail, gives an aspect so much resembling that of a lizard, that these creatures are commonly known by the title of scaly lizards: they may be allowed, however, in a general view of the animal kingdom, to form a kind of shade or link of approximation between the proper viviparous quadrupeds and the true lizards.

They are animals of a harmless nature, and feed in the same manner as the ant-eaters, by thrusting out their very long tongue into the nests of ants and other insects, and expelling their prey by suddenly retracting it, leaving no teeth, and differing from the

ant-eaters in scarcely any other circumstance than that of their scaly integument. They are found in India and the Indian islands.

1. Manis tetradactyla, long-tailed manis. This animal, known in India by the name of the platenigan, is of a long and slender body, and tapers gradually to the tip. The legs are very short, scaled like the body, and on each of the feet are four claws, of which those on the fore feet are stronger than those of the hind. The colour of the whole animal is dark brown, with a cast of yel-lowish, and with a glossy or polished surface.

The manis tetradactyla grows to the length of five feet, measuring from the tip of the nose to the extremity of the tail.

2. Manis, a genus of quadrupeds of the order of bony animals, with slaty, or greyish, or greyish-brown, or very dark brown, or black, or very dark yellow, or yellow, or a kind of yellowish brown, tongue cylindrical and extended; mouth narrowed into a snout; body covered with scales. The genus manis presents an appearance not less extraordinary than that of the genera or amamiola; being covered on every part, except on the belly, with extremely strong and large homy scales, constituting a suit of armour still more powerful than in the following genus, and capable of defending the animals, when rolled up, from the assaults of the most fierce enemies. killed his antagonist, it was made manslaughter in both. Again: there were two men in a room quarrelling; a brother of one of them standing at the door, who could not get in, cried out to his brother to make him sure, and the brother killed his antagonist: it was likewise manslaughter in both.

But if any person shall stab another, not having his weapon drawn, or not struck his first, so that he dies within six months, although he be not in mortal aboriginal, it is felony, by the jurisdiction of the place.

This crime, though felony, is within benefit of clergy; and the offender shall be burnt in the hand, and forfeit all his goods and chattels; but by stat. 19 Geo. III. c. 74, it is made lawful for the court to commute this punishment for a moderate fine and imprison-ment.

MANTELETS, in the art of war, a kind of moveable parapets, made of planks about three inches thick, nailed one over another, to the height of almost six feet, generally carried on wheels upon little wheels, so that in a siege they may be driven before the pioneers, and serve as blinds to shelter them from the enemy's small shot.

MANTIS, a genus of insects of the order Hemiptera. The generic character is, head unstriated, armed with joints or spines; thorax setaceous; legs, in most species, composed, serrated beneath, and furnished with a single claw and a setaceous, lateral, jointed foot; hind legs smooth, formed for walking. This is one of the most singular genera in the whole class of insects; and imagination itself can hardly conceive shapes more strange than those ex-hibited by some particular species. See Pl. Nat. Hist. fig. 259.

The chief European kind is the mantis oratoria of Linnaus, or camel cricket, as it is often called. This insect, which is a stranger to the British isles, is found in most of the warmer parts of Europe, and is entirely of a beautiful green colour. It is nearly three inches in length, of a slender shape, and in its general sitting posture is observed to hold up the two fore legs, slightly bent, as if in an at-titude of prayer: for this reason the super-inction of the vulgar has conferred upon it the religious name of the hollow eye; and a popular notion has often prevailed, that a child or traveller having lost his way would be safely directed by observing the quarter to which the animal pointed when taken into the hand. In its real disposition it is very far from sanctity, preying with great rapacity on any of the smaller insects which fall in its way, and for which it lies in wait with anxious avidity in the posture at first mentioned, seizing them with a sudden spring when within its reach, and devouring them. It is also of a very venomous nature; and when kept with others of its own species in a state of capiti-ality, will attack its neighbour with the utmost violence, till one or the other is destroyed in the contest.

Among the Chinese this quarrelsome property in the genus mantis is turned into a similar entertainment with that afforded by fighting cocks and quails.

The mantis praecia is a native of many parts of Africa, and is the supposed idol of the Hottentots, which those superstitious people are reported to hold in the highest veneration, the person on whom the adored insect happens to light being considered as favoured by the distinction of a celestial visitant, and regarded ever after in the light of a saint. This species is of the same general size and shape with the M. oratoria, and is of a beautiful green colour, with the thorax ciliated or spined on each side, and the upper wings each marked in the middle by a semitransparent spot, resembling the notch by which is the extremity of the circle; and that the lines drawn to measure the latitude, which are parallel to each other, or nearly so, must, in order to preserve as nearly as possible the proportions of the points of intersection with the meridians, form segments of circles, of which no two are parallel or concentric.

There may be as many different projections as there are points of view in which a globe can be seen, but geographers have generally chosen those which represent the poles at the top and bottom of the map; these, from the delineation of the lines of latitude, longitude, are called the stereographic, orthographic, and globular projections.

We do not propose to detain the reader with a description of all the projections, some of which are so numerous (for the purpose of correctly representing maps) as to be consigned entirely to oblivion. But as the projection of maps is a pleasing and instructive exercise, and indeed indispensable necessary to the right understanding of geo-graphy to students, we shall describe the manner of constructing the map of the world.

With regard to the stereographic projection it may be observed, that among the various positions assignable to the eye, there are three, which, in a position plane, give the eye the plane is placed either in the points D, fig. 1, or removed to an infinite distance; and hence this projection is liable to the great errors of distorting the form of the countries represented upon it much more than is necessary.

The only advantage is, that of the lines of latitude and longitude intersect each other at right angles.

The being observed by that excellent astronomer, Mr. de la Hire, he invented a re-modify for the inconvenience, by assigning to the eye a position at the point O, fig. 1, the distance of which from the globe is D equal to the radius of the globe, and hence the right line GO, which bisects the qua-adrant EC, also bisects the radius EC, and produces the similar triangles OFG, and ODE; and thus the other parts of the quad-rant DC, and in the manner of the whole semicircle ACE, are represented in the projection nearly proportionable to each other, and to sense perfectly so. The delineation of the earth and sea upon this projection (which, as coming to a true repre-sentation of the globe, is called the globular projection), is equal to the stereographic in point of facility, and vastly superior to it in point of truth.

Geometrical construction of the globular projection.—From the centre C, fig. 2, with any radius, as CB, describe a circle; draw the diameters AB, and BD, 90, at perfect right angles to another, and divide them into equal parts, and divide each of the equal parts into nine equal parts, each of which contains degrees; if the scale admits of it, every one of these divisions may be sub-divided into degrees; next, to draw the meridians, suppose the meridian 80° W. of Greenwich, we have given the two poles 90, and makes one of the meridians be supposed equal in length to the half of the periphery (which is not quite two-thirds), it follows of course, that the countries delineated upon, or near, these lines, must be reduced to somewhat less than two-thirds of the length of the actual extent, which lie at the extremity of the circle; and that the lines drawn to measure the latitude, which are parallel to each other, or nearly so, must, in order to preserve as nearly as possible the proportions of the points of intersection with the meridians, form segments of circles, of which no two are parallel or concentric.
for the arc
80° 80° 80° 80° the radius \( r = \) 18.44
70° 70° 70° 70° = 36.88
60° A 60° A 60° A 60° = \( A \). Arctan = 48.16
50° 50° 50° 50° \( \theta = \) 65.3
40° 40° 40° 40° = 87.11
30° 30° 30° 30° = 108.13
20° 20° 20° 20° = 128.60
10° 10° 10° 10° = 148.32

(2) The Stereographic Projection of the Sphere on the Plane of a Meridian.

Draw a circle NESW, fig. 4, and the two diameters of it at right angles with each other.

Divide the arc of each quadrant into nine equal parts.

From the point P, draw dotted lines to each point of division on the arc WN.

The intersections made by this means on the meridian CN, mark the line of semantigons, which must also be set off on the other three semidiameters, CS, CW and CE.

Draw likewise two dotted lines from E to 23° 1° and 66° 32° for the tropic and polar arcs, which must also be set off on the semidiameter CS.

Each point of intersection on GN, and the corresponding points on the arcs WN and EN, are the three points through which the arcs of latitude must pass; and their centres will be in the line NS produced.

Take the radius of the same circle for a scale; divide it into nine equal parts, and each of those parts into ten other parts, as before.

The following table exhibits the length in those parts of the radius, which must be taken to describe each respective arc.

For the arc
80° 80° 80° 80° the radius \( r = \) 15.77
70° 70° 70° 70° = 31.54
60° A 66° A 66° A 66° = \( A \). Arctan = 39.18
50° 50° 50° 50° \( \theta = \) 51.96
40° 40° 40° 40° = 63.52
30° 30° 30° 30° = 75.12
20° 20° 20° 20° = 86.13
10° 10° 10° 10° = 96.85

The two polar points N, s, and the semitangent on CE, mark the three given points through which each meridian line must pass, and the following table gives the length of each radius to describe the meridian arc.

For the arc N,S, the radius \( s = \) 91.4
S.N. = 95.78
N.S. = 104
S.N. = 117.5
N.S. = 140
S.N. = 157.5
N.S. = 160
S.N. = 175.5
N.S. = 190
S.N. = 200
N.S. = 215.5

(3) The Globular Projection of the Sphere on the Plane of the Equator.

On the centre P, fig. 5, draw the circle WNE, to represent the equator.

Draw the two diameters, WE and NS, at right angles to each other.

Divide the arcs of the four quadrants into nine equal parts; each of the parts will be equal to ten degrees.

Number them from N towards P, 10, 20, 30, 40, 50, &c.

On the centre P draw circles passing through those points of division, which will be the circles of latitude.

For the arc, set off 283° from P towards N; do the same at N towards P, for the other arc.

Through each of those points draw an oblique circle.

Draw diameters from the divisions on one half of the circumference to the corresponding divisions on the opposite one, to represent the meridians, and this will complete the projection.

(4) The Stereographic Projection of the Sphere on the Plane of the Equator.

Draw the circle NW, S, E, fig. 6, and the two diameters at right angles with each other.

Divide the arcs of each of the four quadrants into nine equal parts; subdivide each of those parts into ten degrees; number those degrees 10, 20, 30, &c.

Divide the latitudes from the divisions on one side of the circumference to the corresponding divisions on the other, which will represent the meridians.

For the parallels of latitude, project a line of semitangents as directed in the 3d case.

On the centre P describe circles passing through the semitangents, which will complete the diagram.

Note. The foregoing methods of projecting the sphere are the best. There is another method sometimes used, viz. the projection on the plane of the horizon when any assumed place is considered as the centre; but as this method is rarely used, it need not be elucidated.

The orthographic projection is in fact so erroneous, that it is never adopted for that purpose, and applied only to dialing.

The gnomonical projection is only applicable to dialing.

We shall now point out the advantage and disadvantage of Mercator's projection.

A method has been found to obviate some of the difficulties attending all the circular projections by one, which, from the person who first used it (though not the inventor), is called Mercator's projection. In this there are some but right lines; all the meridians are equidistant, and continue so through the whole extent; but, on the other hand, in order to obtain the true bearing, so that the compass may be applied to the map or chart for the purpose of navigation, the spaces between the parallels of latitudes (which in truth are equal, or nearly so) are made to increase as they recede from the equator in a proportion which, in the high latitudes, becomes prodigiously great.

The great advantages peculiar to this projection are, that it always retains its true bearing with respect to all other places; the distances may be measured with the greatest exactness by proper scales, and all the lines drawn upon it are right lines; for these reasons it is much adopted in drawing maps or charts for the use of navigators.

We shall now show the method of this kind of projection.

Mercator's or Wrigh's projection of maps.—Draw the line AB, fig. 7, and divide it into as many degrees as your map is to contain in longitude, suppose 90°. At the extremities A and B raise perpendiculars, to which draw parallel lines at every single, fifth, tenth, or twentieth degree of the equator, for the meridians; as in the figure, where they are drawn at every tenth degree. This done, put one foot of the compasses in the point A, and extending the other to the point in the first meridian at B; or, for greater exactness, to some more distant point, as B 90°, etc., describe the quadrant F, which divide into nine equal parts, and drawn lines from A to each point of the division; or, to avoid scoring the paper, the scribe can cut the first meridian GH, at every tenth degree's distance. Lastly, because the distances of the parallels from one another are marked.
To use this table, divide the assumed degree into sixty parts by a diagonal line, fig. 9; look for the number of miles answering to the degree of lat. 49, which is 39, 36, say 39°, which take off the scale, fig. 9, at a, and set off four times from C towards B, and the same from C towards A. The top meridian is 50° of lat. opposite which, in the table, is 33, 53, say 33°, which take from the scale, fig. 9, at b, and set off four times from D towards E, and the same from D towards F. Draw the meridians to the corresponding divisions at top and bottom, of which 0 is the meridian of London. Second. When the meridians and parallels are correctly marked, proceed to project a map of Europe by this method:

[Diagrams and text discussing the projection process, with references to the use of the table and the projection method, including the use of meridians and parallels to represent geographical features and distances.]
Marble, polishing of, is performed by first rubbing it well with a freestone, or sand, till the strokes of the axe are worn off, then with pumice-stone, and afterwards with emery.

Marbling, in general, the painting anything with veins and clouds, as to represent those of marble. Marbling of books or paper is performed thus: Dissolve four ounces of gum-arabic into two quarts of fair water; then provide several colours mixed with water in pots or shells, and with pencils peculiar to each colour, sprinkle them by way of mixture upon the gum-water, which must be put into a trough, or some broad vessel; then with a stick curl them, or draw them out in long lines, and let them dry in the air. Having done this, hold your book or books close together, and only dip the edges in, on the top of the water and colours, very lightly; which done, take them off, and the plain impression of the colours will remain above upon the leaves; and as well the ends as the front of the book in the like manner. Marbling books on the covers is performed by forming clouds with aquafortis, or spirit of nitre, fringed with ink, and afterwards glazing the covers.

Marcgravia, a genus of the polyandra monogyne class of plants, the corolla whose of consists of a single petal, of a conico-oval figure; and its fruit is a glbose berry, with a single cell, containing a great number of very small seeds. There is one species, a shrub of the West Indies.

Marcianita, a genus of thecryptogama class of plants, the corolla of which is monopetalous, tubular, and shorter than the cup; in the lower cavity of which are contained several naked seeds, of a roundish but compressed figure. There are seven species, five of them British.

Marcionites, Christians in the second century, thus denounced from their leader Marcion, who maintained that there were two principles or gods, a good and a bad one.

Marcosians, a sect of Christians in the second century, so called from their leader Marcus, who represented the Supreme God as consisting of two natures, but a quaternity, viz. the indigible, silence, the father, and truth.

Mare. See Eaurus.

Margaritiera, a genus of the dicra octandra class and order. The male calyx is four-toothed; corolla four-petalled; female calyx and corolla as above; styles four or five. There is one species, a native of Surinam.

Marica, a genus of the trignia monogyne class and order. The calyx is six-parted; stigma petal-form, trident; capsule three-celled; inferior. There is one species, a fleshy bulb of China.

Marilla, a genus of the class and order polyandra monogyne. The calyx is five-leafed; corolla five-petalled; capsule four-valved, many-seeded; stigma simple. There is one species, a native of the West Indies.

Mark, knights of St., an order of knighthood in the republic of Venice, under the last of the doges. The insignia of the order are, gules, a lion winged or, with this device, "Pax tibi Marce evangelista." This order is never conferred but on those who have done signal service to the commonwealth.

Mark, or Mar, also denotes a weight used in several states of Europe, and for several commodities, especially gold and silver. In France, the mark is divided into 8 oz. or 64 drachms, or pennyweights, or 160 esterlines, or 300 marks, or 635 lbs., or 4608 grains. In Holland the mark weight is also called troy-weight, and is equal to that of France. When gold and silver are sold by the mark, it is divided into 24 carats, or parts. Mark is also used among us for a money of account, and in other countries for a coin. The English mark is two-thirds of a pound sterling, or 13s. 4d. and the Scotch mark is of equal value in Scotch money of account. In the 17th century, to mark goods, or label them, which was usual in Amsterdam, is also a money of account, equal to one-third of the rix-dollar, or to the French livre: each mark is divided into 16 solds-lubs. Mark-lubs is also a Danish coin equal to 10 solds-lubs. Mark is also a copper and silver coin in Sweden.

Market. A market is less than a fair, and is commonly held once or twice a week. According to lrancon, one market ought to be held in the midst of the town, and a half and a third of it; but no market is to be kept within seven miles of the city of London; but all butchers, victualers, &c. may hire stalls and standings in the fleshmarkets there, and sell meat and other provisions, four days in a week. Every person who has a market is entitled to receive toll for the things sold in it; and, by antient custom, for things standing in the market, though they are sold: but impeding a market in any other manner than it is granted, or exporting of tolls or fees where none are due, they may be forfeited.

In London every shop in which goods are exposed for sale is covered over, excepting such things only as the owner or proprietors trade in: though the sale is in a warehouse, and not publicly in the shop, the property is not altered. But if goods are stolen from one, and sold out of the market over, the property is not altered, and the owner may take them wherever he finds them. 5 Rep. 83.

If a man buy his own goods in a market, the contract shall not bind him, unless the property had been previously altered by a former sale.

Marle. A mixture of carbonat of lime and clay, in which the carbonat considerably exceeds the other ingredient, is called marle. Its structure is earthy. Opaque, sometimes in powder. Specific gravity from 1.6 to 2.877. Colour usually grey, often tinged with other colours. Effervesces with acids. Some marles crumble easily to a powder when wet; others retain their hardness for many years. Marles may be divided into two varieties: 1. Those which contain more silica than alumina. 2. Those which contain more alumina than silica.

Marlow has called the first of these siliceous, the second argillaceous marle. Attention should be paid to this distinction when marles are used as a manure.

Marle, bituminous, is found in different parts of Germany. Colour greyish or brownish. Used for paving. It is also used to make stepping-stones, pavers, flat or waved. Opaque. Feels soft. Easily broken. Moderately heavy. Effervesces with acids. Burns before the blowpipe, leaving black scorish.

Marly, or marly, are tared white skins, or long widths or lines of untwisted hemp, dipped in pitch or tar, with which cables and other ropes are wrapped round, to prevent their fretting and rubbing in the blocks or pulleys through which they pass. The same serves in artillery upon ropes used for rigging guns, usually put up in small parcels called skins.

Marmotte. See Mus.

Marquise. See Letters of Marquise.

Marquetry, or Inlaid work, is a curious work composed of several fine hard pieces of wood, of various colours, fastened in thin slices on a ground, and sometimes enriched with other matters, as silver, brass, tortoiseshell, &c.; and by these means the art is now capable of imitating any thing; whence it is by some called the art of painting in wood.

The ground upon which the pieces are to be arranged, and the glue is usually of well-dried oak or deal; and is composed of several pieces glued together, to prevent its warping. The wood to be used in marquetry is reduced into leaves of the thickness of a line, or the 12th part of an inch, and is either of its natural colour, or stained, or made black to form the shades by other methods: this some perform by putting it in sand heated very hot over the fire; others by steeping it in lime-water and sublimates; and others in oil of sulphur. The wood being of the proper colours, the contours of the pieces are formed according to the parts of the design they are to represent: this is the most difficult part of marquetry, and that which requires the most patience and attention.

The two chief instruments used in this work are a saw and a wooden vice, which has one of its claps fixed, and the other movable, which is opened in a line by a foot, by means of a cord fastened to a treacle.

Marquis, a title of honour, next in dignity to that of duke, first given to those who commanded the marches, that is, the borders and frontiers of countries.

Marqueses were not known in England till the reign of king Richard II. and the year 1387.

Marriage, a contract, both civil and religious, between a man and a woman.

Taking marriage in the light of a civil contract, the law treats it as it does all other contracts: allowing it to be good and valid in all cases where the parties, at the time of making it, were, in the first place, willing to contract; secondly, able to contract; and, lastly, actually did contract in the proper forms and solemnities required by law. 1 Black. 433.

By several statutes a penalty of 100£ is inflicted for marrying any persons without banns or licence. But by 25 G. II. c. 33, if any person shall solemnize matrimony without banns or licence obtained from some persons having authority to grant the same, or in any other place than a church or chapel where
MARROW. See Anatomy.

MARRUBIUM, white horhound, a genus of the gynopetria order, is highly esteemed for its medicinal properties, and in the natural method ranking under the 43rd order, verticillatae. The calyx is salver-shaped, rigid, and ten-striated; the upper lip of the corolla bifid, linear, and straight. There are 16 species, 3 of which is the vulgar, a native of Britain, growing naturally in waste places, and by ways-sides near towns and villages, but not common. It has a strong and somewhat musky small, and bitter taste. It is reputed antimonial and resolvent; an infusion of the leaves in water, sweetened with honey, is recommended in asthma and phthisical complaints, and most other diseases of the breast and lungs.

MARS, in astronomy, one of the superior planets, is round the sun in an orbit between those of the earth and Jupiter. See Astronomy.

MARSHAL, in its primary signification, means an officer who has the command or care of horses; but it is now applied to officers who have very different employments, as Earl-marshals, knight-marshals, or marshal of the King's house.

Marshall of the king's bench, an officer who has the custody of the king's bench pleas in Southwark. This officer is obliged to give his attendance, and to take into his custody all persons committed by that court.

Marshall of the exchequer, an officer to whom that court commits the king's debtors.

MARSHALLEA, a genus of the class and order syngeasia polygium aquilus, little known.

Marshall, a coat, in heraldry, is the disposal of several coats of arms belonging to distinct families, in the same escutcheon or shield, together with their ornaments, bats, and appurtenances.

MARSHALSEA-court, a court of record, originally instituted to hear and determine cases between the servants of the King's household and others within the verge of the court, and of a value of trespass, where either party is of the King's family; and of all other actions personal, wherein the parties are the King's servants; but the court has also power to try all personal actions, as debt, trespass, slander, trover, action on the case, &c., between party and party, the liberty whereof extends 12 miles east and west of Whitehall. The judges of this court are the steward of the King's household, and high-marshall for the time being; the steward of the court, or his deputy, is generally an eminent counsel.

If the cause of importance is brought into this court, it is generally removed into the court of the King's bench or common pleas by a habeas corpus cum causa.

MARSILEA, a genus of the cryptogamia class of plants, without any corolla or cup in the flowers, and placed among an oblong conic body; the fruit is of a roundish figure, consisting of four cells, in each of which are contained several roundish seeds. There are three species.
The master is also answerable for any injury arising by the fault or neglect of his servant when executing his master's business, 6 T. R. 659: but if there is no neglect or default in the servant the master is not liable. Esp. Rep. 533.

If a smith's servant lanes a horse whilst shoeing him, or the servant of a surgeon makes a wound worse, in both cases an action for damages will be against the master, and not against the servant. But the damage must be done while the servant is actually employed in his master's service, otherwise he is liable to answer for his own misbehavior or negligence.

A master is likewise chargable if his servant casts any dirt, &c. out of the house into the common street; and so for any other nuisance occasioned by his servants, to the damage or annoyance of any individual, or the common nuisance of his master's property. Lord Raym. 764.

A servant is not answerable to his master for any loss which may happen without his wilful neglect; but if he is guilty of fraud or gross negligence, an action will lie against him by his master.

A master is not liable in trespass for the wilful act of his servant; as by driving his master's carriage against another, done without the direction or consent of his master, no person being in the carriage when the act was done. But he is liable to answer for any damage arising to another from the negligence or unskilfulness of his servant acting in his employment. M'Kinnon v. Crickitt, Mich. 41 G. III.

MASTER OF ARTS, is the first degree taken up in foreign universities, and for the most part in those of Scotland, but the second in Oxford and Cambridge; candidates being admitted to it till they have studied seven years in the university.

MASTER IN CHANCERY. The masters in chancery are assistants to the lord chancellor and master of the rolls; of these there are some ordinary, and others extraordinary: the masters in ordinary are 12 in number, some of whom sit in court every day during the term, and have referred to them interlocutory orders for stating accounts, and computing damages and theike; and they also administer oaths, take affidavits, and acknowledgments of deeds and recognizances. The masters-extraordinary are appointed to act in the country, in the several counties of England, beyond 10 miles distant from London; by taking affidavits, recognizances, acknowledgments of deeds, &c. for the case of the suits of the court.

MASTER OF THE FACULTIES, an officer under the archbishop of Canterbury, who grants licences and dispensations.

MASTER OF THE HORSE, a great officer of the crown, who orders all matters relating to the king's stables, races, bred of horses, and commands the equerries and all the other officers and tradesmen employed in the king's stables. His coaches, horses, and attendants, are the king's, and bear the king's arms and livery.

MASTER OF THE ORDNANCE, a great officer, who has the chief command of the king's ordinance and artillery.

MASTER OF THE ROLLS, is an assistant to the lord chancellor of England in the high court of chancery; and in his absence hears causes there, and gives orders. His salary is 1,200 l. a year.

MASTER OF A SHIP, the same with a captain in a merchantman; but in a king's ship he is an officer who inspects the provisions and stores, and acquaints the captain with what is not good, takes particular care of the discipline of the ship and crew, and gives directions for stowing the hold; he navigates the ship under the directions of his superior officer; sees that the log and log-book are duly kept; observes the appearance of coasts; and navigate down his journal any new shoals or rocks under water, with their bearing and depth of water, &c.

MASTER AT ARMS, in a king's ship, an officer who daily, or by turns, as the captain appoints, is to exercise the petty officers and ship's company, to place and relieve sentinels, to secure the port, to put out according to the captain's orders; to take care that the small arms are kept in good order, and to observe the directions of the lieutenant at arms.

MASH, in field fortification: it sometimes happens that a ditch or fosse must be dug in an exposed situation; in this case it will be absolutely necessary for the artificers and workmen to get under cover by means of masking themselves in such a manner as to answer the double purpose of excluding their immediate object, and of deceiving the enemy with respect to the real spot they occupy.

To effect the latter purpose several masks must be hastily thrown up, whilst the men are employed behind one; by which means the enemy will either mistake the point, or be induced to pour his fire in several directions, and thus weaken its effect.

A mask is generally six feet high. Bases made of wad or wood are too expensive on these occasions; nor are gables, stuffed with fascines, seven or eight feet high, to be preferred; for if the fascines are tied together they will leave spaces between them in the gables; and if they are not bound together, they will be so open at top as to admit shot, &c.

In order to obviate these inconveniences the following method has been proposed: Place two chandeliers, each seven feet high and two broad, between the uprights, after which fill up the vacant spaces with fascines of the same height, upon which the fascines may rest. One box and a half of epaulment will require two chandeliers and 60 fascines to mask it.

The engineer, or artillery officer, places himself behind this mask, and draws his plan.

As you must necessarily have earth, &c. to complete your work, these articles may be brought in shovels, sacks, or baskets; and if the quarter whence you draw them should be exposed to the enemy's fire, cover that place, as well as the line of communication, between the trenches, or the parallels, with a mask.

MASTOIDES. See Anatomy.

MATCH, a kind of rope slightly twisted, and prepared to retain fire for the uses of artillery, mines, fireworks, &c. It is made of hemp, tarp, spun on a wheel like cord, but very slack; and is composed of three twists, which are afterwards again covered with tow, so that the twists do not appear: lastly, it is boiled in the leaves of old vines. This, when once ignited, the end being gradually and regularly, without ever going out, till the whole is consumed: the hardest and driest match is generally the best.

MATCH, quick, used in artillery, is made of three cotton strands drawn into lengths, and put into a bottle just filled with nitre or saltpetre, white vinegar, and then a quantity of salted petroleum and mealed powder is put into it, and boiled till well mixed. Others put only saltpetre into water, and after that take it out hot, and lay it into a trough with some powdered treacle, moistened with some spirits of wine, thoroughly wrought into the cotton by rolling it backwards and forwards with the hands; and when this is done they are taken out separately, drawn through mealed powder, and dried upon a line.

MATERIA MEDICA. "The materia medica (says Dr. Darwin) includes all those substances which may contribute to the restoration of health." If, however, medicine be defined the art of preventing, as well as of curing, diseases, the science of which we are now to treat ought, by consequence, to comprehend the preservatives of living existence, as well as the restoratives of healthy action. Instead, therefore, of restricting this article to the mere preservative and discussion of drugs, we shall, in the first place, introduce some general remarks on those substances which are employed as articles of diet or food. PART I.

DIETETICS.

Organic life appears to be influenced and supported by two leading principles: 1st, fibrous excitation; and 2dly, the substitution of nutrimonious particles, in place of those which are constantly dissipated or abraded. The power by which this last object is effected has been demonstinated by the author of Zoonomia, animal appettency. The principal and prime organs by which it is exercised, or the media through which new matter is originally communicated, are those which are termed the digestive and assimilating: it has, however, recently been conjectured that the organs of digestion are not the sole organs of nutrition, but that both the external surface of the body, and likewise the lungs, are media for the admission into the system of procures which we include in the class nutritia, in the materia medica of the author just quoted, to comprehend not merely those substances which are received...
into the stomach as food. But also the matter which is taken into the lungs in the act of respiration, as likewise air, water, and other substances that may be applied naturally or artificially to the outer skin. To enquire into the grounds upon which this doctrine is established, that there are lungs, the stomata, and the surface of the body, each affords instruments in common of actual nutrition, does not fall within the province of the present article. See Physiology. It will be proper here to confine ourselves to the general consideration of what is usually denominated animal and vegetable diet.

OF ANIMAL FOOD.

That man is designed by nature for a mixture of animal and vegetable food, is obvious from the structure of his organs, both of mastication and digestion. That the flesh of animals contains more nutritive matter, and that it stimulates the absorbent and secreting vessels more powerfully, than vegetable aliment, is demonstrated by the superior warmth and strength which in a state of health we experience after a meal of flesh than of vegetables; of the former (animal flesh), that, in general, which is of a dark-colour, contains more nutritive matter, and stimulates our vessels with more energy, than the white kinds: indeed the flesh of those animals which are carnivorous, or which live entirely on animal food, seldom enters into the diet of European, or civilized nations. The greater stimulating virtue of this kind of food has been attributed to the greater quantity which it has been supposed to contain of volatile alkali. Dr. Darwin, however, properly questions whether it is not rather the elements only of this principle that are contained even in the strongest dark-coloured animal flesh.

Next in strength to the flesh of carnivorous animals ought to rank that of those animals when killed at full growth, the young of which afford a softer, whiter, more digestible, but less nutritious, food, such as the sheep, the bullock, the hog, and likewise several of the flesh-fish, as lox, eel, herring, mackerel, murrel, lamping, ought to be arranged in this second class. These, with a due mixture of vegetable aliment, constitute the best kinds of food for healthy and athletic individuals, whose digestion is powerful, and who have a firm fibre.

The flesh of young animals, as of lamb, veal, and sucking pigs, afford a less stimulating and nutritious, but more digestible food; these meats are consequently most congenial to persons of less muscular energy, who have more feeble powers of digestion, and who accustom themselves to but little exercise: they are adapted to the hypochoondriac, and should be principally used as aliment by individuals who are disposed to those kind of affections which have received the vulgar indiscriminate appellation of scorbutic.

A still milder, but, in the same proportion, less fortunate food, furnished by the lungs, partridge, pheasant, and their eggs, with oysters and young lobsters. These, from their bland and unacrimonious nature, are generally allowed to convalesce from acute diseases: they are peculiarly suitable to very weak stomachs, and are used in cases in which the creation is more easily digested by the adult stomach, on account of its containing less of the caseous, or cheesy part; it is likewise on this account more nutritious. Butter contains still more nutrition, and is likewise, if not taken to excess, exceedingly easy of digestion, and is by no means calculated to generate unpleasant humours in the body. If given without any separation of its principles by artificial preparation, it might be admitted into the diet of infancy with much greater propriety than other articles which are employed with less apprehension of injury. Buttermilk is agreeable, bland, and gently nutritious. Why is the mouth and the digestive powers of an infant less powerful, than in the adult? It is on this account ordered with the utmost propriety to those invalids whose constitutions have been rendered too irritable to bear the stimulus of more solid and nutritive aliment. Cheese is of various kinds: some, chiefly principal from the greater or less quantity of cream that it contains. Those cheeses which are broken to pieces in the mouth with most readiness are, for the most part, most easy of digestion, and most nutritious. Moreover, all kinds of cheeses are a considerable time in undergoing chemical change in the stomach; and on this account, although difficult of digestion, do not disagree with weak stomachs. Dr. Darwin observes that he has seen toasted cheese vomited a whole day after it was eaten, without having become perceptibly altered, or given any uneasiness to the patient.

Next, cow's milk is the food of infants, and is by far the best substitute for the milk of the mother, if this last be not afforded in sufficient quantity or quality by the parent, which, however, is seldom the case. The milk of an adult cow, goat, or sheep, is usually curdled when kept in the air, which is always curdled before it is assimilated, is consequently digested with more facility in the earlier than in the more advanced periods of life. It is on this account likewise that certain vegetable substances, which have a great tendency to acidity, are exceedingly injurious to the infantile stomach. See the article Infancy.

OF VEGETABLE FOOD.

The seeds, roots, leaves, and fruits, of plants, particularly the two former, constitute a very material part of the food of mankind. According to the opinion of Dr. Cullen, and other physiologists, the quantity of actual nourishment that these contain, is in proportion to the quantity of sugar that they can be made to produce; it is imagined that the mucilage which the farinaceous seeds contain, is chemically combined with that sugar, and that this starch, in the processes to which the seeds are afterwards subjected, or by digestion in the stomach, is at length converted into saccharine principle. See Physiology.

The farinaceous seeds are wheat, barley, oats, rye, millet, maize or Indian corn, &c. The roots of this class of plants are potatoes, the common carrot, beet, and polydory. Those with less of the saccharine principle, and which afford a tender farina, are the turnip, cabbage, the purslane, parsley root, asparagus, and many others, of which, if less nutritious, are better suited to weakly organs of digestion than those in which the sugar is more abundant.

Other vegetables contain oil, sugar, mucilage, or acid; in various proportions, diluted with much water; these are but slightly nutritious; and are, for the most part, injurious to delicate stomachs especially, unless taken with moderation; these are the apple, pear, plum, apricot, pear-tree, peach, strawberry, grape, orange, melon, cucumber, dried figs, raisins, and a great variety of other roots, seeds, leaves, and fruits. Of these it may be observed generally, that those which are cold, watery, and sweet, are most calculated to prove indigestible, and consequently injurious.

DIFFERENT METHODS OF DRESSING VITALS.

Various modes of preparing and dressing both animal and vegetable articles of food have been contrived, in order to render them more palatable, and better adapted to the stomach. By boiling, animal flesh is, in a measure, deprived of its nourishing juice, which is with more or less facility given out to, and incorporated with, the broth: this last then contains the most nutritious part of the meat, but in general stronger than it ordinarily is used, it is too diluted to admit of an easy digestion. Broths likewise have a remarkable tendency to acidity, particularly when made from the flesh of young animals, as of lamb and veal; and on this account also are much less congenial to weak stomachs than is generally imagined. The various jellies, which contain the gelatins and nutritious, to the exclusion of the fibrous part of the flesh, are in general much more suitable to the invalid and the convalescent than either broths or soups. Perhaps the most eligible mode of preparing animal food is by the process called stewing; for by this means all the nutritive parts of the flesh are concentrated and preserved. It is scarcely necessary to observe that the gravy of boiled meat contains its nutritive parts in a state of concentration; it is digested with facility; and gravy is therefore the best mode of giving animal food to very young infants.

Roasting preserves the nutritious part of flesh from dissipation in a greater degree than boiling: and it has been asserted by an observant author (Dr. Willich) that 'one pound of roast meat is, in real nourishment, equal to two or three pounds of boiled meat.' It ought however to be noticed, that the fat of meat treated in this way has undergone some degree of chemical decomposition from its exposure to heat, and is in consequence more oppressive to delicate stomachs, and generally less salutary, than that of boiled flesh. Both baking and frying are upon similar principles; and in the methods of preparing animal food. Smoked meats, as prepared hams, are hard of digestion. They should only be taken in small quantities, and rather as condiment than food.
MATERIA MEDICA.

Water is the natural and proper drink of man. It is the basis of all other fluids; and the larger proportion of water that enters their composition, the more easily, in a state of health, and provided proper food has been taken, are the solution and digestion of such food effected.

This fluid, however, is never or seldom taken in a state of entire purity. Even in nature's laboratory it is invariably impregnated with foreign substances; and it is this admixture of extraneous matter which constitutes its varieties. Thus we have snow water, rain water, spring water, river water, and water from lakes, wells, and swamps, each possessing their individual characteristics.

Spring water is, in general, most free from impurities; it is, however, less suited for drink than the water of rivers, as it almost constantly contains calcareous, or saline ingredients. The calcareous earth dissolved in the water of many springs, has been supposed indeed by Dr. Darwin to contribute to our nourishment in the manner that lime proves useful in agriculture. This principle, however, is not perhaps fully established; and we believe that too much is contributed by general theories in the specific qualities of water, as modifying both the bodily and intellectual character of individuals and nations. The cestrin and fatuity of the Alpine valleys were formerly attributed to the waters of these countries, but are now more commonly, and we believe more justly, referred to constitutional propensity, innutritious food, and a humid unhealthy atmosphere.

That water however possesses great varieties, according to the nature of the soil and situation of the place in which it is produced or contained, is undeniable; and we shall here extract part of what is observed on these varieties by an attentive and judicious observer.

"Spring water," says Dr. Willich, "originates partly from that of the sea, which has been thrown out by subterranean heat, and partly from the atmosphere. As it is dissolved and purified in a variety of ways before it becomes visible to us, it is lighter and purer than other waters."

"River water," opened in a sandy soil are the purest. The water faintly a well is used, the better; for the longer water stands unmoved, the sooner it turns putrid.

"Lake water much resembles river water, but being agitated it is more impure. The water which, in cases of necessity, is obtained from swamps and ditches, is the worst of all; because a great variety of impurities are there collected, which, in a stagnant and soft soil, readily purify.

"Rain water is also impure, as it contains many saline and oily particles, soon putrefy, and principally consists of the joint exhalations of animals, vegetables, and minerals, of all seeds of plants, and the like. Rain water is particularly impure in places filled with many noxious vapours; such as marshy countries, and large manufacturing towns, where the fumes of metallic and other substances are mixed with rain. In high and elevated situations, at a distance from impure exhalations, if no strong winds blow, and after a gentle shower, rain water is then purest. In summer, however, on account of the copious exhalations, rain water is most objectionable.

"Snow water possesses the same properties as rain water, but is purer; both are soot, that is, without so many mineral and earthy particles as spring, well, and river waters. Hall water, being produced in the higher regions of the atmosphere, is still purer from its cong lations. Lastly, deco, as it arises from the evaporation of various bodies of the vegetable and animal kingdoms, is more or less impure, according to the different regions and seasons.

On the different kinds and qualities of fermented and spirituous liquors, it does not fall within the compass of the present article to treat. They all consist of water as their base or vehicle, of more or less spirit according to their different degrees of strength, of sugar, and of the particular ingredient by which their nature is determined; such as the grape in wine, the apple and pear in cider and cider-pear, and the like. (See the respective articles in their alphabetical order.) It is only necessary here to observe, that with few exceptions, fermented liquors, when immediately taken, are more detrimental than elementary fluids, in proportion to the quantity that they contain of alcohol, or ardent spirit.

With respect to the China tea and the coffee-berry, which have lately come into such general use in this country, we believe them to be much less injurious to the animal economy than some theorists have been disposed to conjecture. In excess, however, and when indulged in as substitutes for, and, in some times the case, almost to the exclusion of, nourishing diet, they are highly deliciouse, as they tend to the induction of a morbidly irritable condition of the nervous system. It deserves to be remarked, that these stimulants do not, like alcohol, produce those formidable, and often irreducible, disorders, affections of the liver, drop, and apoplexy.

An enumeration of spices (which, like spirituous liquors, are used as articles of diet with too great freedom) will be found under the head Aromatic, in a subsequent section of this article.

PART II.

MEDICINALS.

We now proceed to the second division of our subject, or to the consideration of the materia medica in its more ordinary and limited signification.

Various divisions and modes of classification of those articles which are used in medicine, have been proposed and adopted by different authors. Some systematic writers arrange the articles of the materia medica according to their alphabetic order; but others have taken for the basis of their arrangement the more sensible properties of drugs, as detected by the taste; thus reducing medicines to the arid kinds of bitterness, sweetness, astringency, acidity, &c. These have been regulated in their classification of medicinal articles, by their characters as objects in natural history. "As, however, the study
MATERIA MEDICA.

of the materia medica is merely the study of the medicinal properties of certain substances, it is evident that the method of arranging them as they agree in producing effects on the living system is the one best calculated to fulfil all its objects." Murray.

Among the different plans of arrangement which have been framed on this principle, that adopted by Mr. Murray, in his late work on the materia medica, appears liable to the fewest objections. It is founded on the principles of Dr. Brown, "that medicines operate by stimulating the living fibre, or exciting it into motion." See the article BRUNONIAN SYSTEM. This proposition, however, was received and applied by its author in too unlimited a sense. In the first place, stimulation differs not merely in degree, but also in kind; or, in other words, one given medicine cannot by any regulation of its quantity be made to produce the same effects which result from the agency of another; some are more diffusible and transient, others more slow and permanent in their action; some affect the universal system in almost an equal degree, while the operation of others is more especially, and in some instances almost exclusively, deviated to a certain part. They have all likewise properties peculiar to themselves.

But besides this general and very important modification of the Brunonian materia medica, it is necessary further to take notice, that medicines sometimes appear to display their agency, even on the living body almost entirely upon chemical or mechanical principles; these last modes of operation, although less common and extensive than were supposed in the antient systems of medicine, must still be admitted as interferring with the universality, and opposing the unqualified assumption, of Dr. Brown, to which we have just alluded.

Guided by these views, Mr. Murray has adopted the general division of medicines under the four heads of universal stimulants, local stimulants, chemical remedies, and mechanical remedies, which are subdivided in the following manner:

<table>
<thead>
<tr>
<th>TABLE OF CLASSIFICATION.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>A. General stimulants.</strong></td>
</tr>
<tr>
<td>a. Antispasmodics.</td>
</tr>
<tr>
<td>b. Permanent.</td>
</tr>
<tr>
<td>b. Local stimulants.</td>

</tr>
<tr>
<td>c. Demulcents.</td>
</tr>
<tr>
<td>c. Emollients.</td>
</tr>
<tr>
<td><em>D. Mechanical remedies.</em></td>
</tr>
</tbody>
</table>

The objections which still lie against this, which we have chosen as the most perspicuous and comprehensive arrangement of medicines, will be urged, as we proceed to make some observations on their indications, in the order of the above table.

The following, then, may be regarded, with some few exceptions, as an abridgment, or condensation, of the materia medica departimt, the out of which the articles of the present collection have been adopted from the last edition, recently published, of the Parmaco- peian collegii regin Medicorum Edinburgensis. In this edition the simples are principally in- cluded by the Linnaean names. We have added, however, the more eusynomy titles, in order to obviate confusion.

**OF NARCOTICS.**

Medicines of this class had, previous to the time of Dr. Brown, been almost universally regarded as sedative, or depressing, even in their primary operation. By a bold, and, in some measure, legitimate generalization, our author has proved that this kind of agency, in the greater number of cases, merely of a secondary nature; and that the symptoms of depressed, or, more properly speaking, exhausted power, resulting from their administration, are consequent upon the irritability that is attendant on the universal system, and very extraordinary manner, the actions of the system. Thus opium, which is one of the most powerful of the narcotics, Dr. Brown maintained is, in the first instance, invariably stimulant; and the same virtue he attributes to the whole range of narcotic, or, as they were formerly characterized, sedative powers.

Although this conclusion is deduced from principles in the main correct, and in its application has been of abundant service in developing the laws of organic existence, it cannot, as we have above remark- ed, be admitted as universal, as the fact must be obvious to all who are not biased by system, that the sedative effects of narcotics are often disproportioned to their previous existing operation, allowing even in such cases for its rapidity and little permanence.

Thus Dr. Murray, in some instances, interferes with the correctness of our author's (Mr. Murray's) classification.

Narcotics are employed medicinally with different and opposite intentions. As stimulants, they are given in various disorders of debility; in intermittent and continued fever, in gout, hysteria, epilepsy, dropsy, &c. As sedatives they are administered to allay pain and irritation, and are consequently largely administered in spasmatic and painful affections. Alcohol, ardent spirit; spirit of wine. For the origin and preparation of this consult the article ALCOHOL. The stimulant effect of alcohol is generally known to be very powerful and diffusible; its exciting power is perhaps, in proportion to its sedative quality, greater than any of the other narcotics. Moderate excitement, with proportionate subsequent languor, results from a moderate dose of spirits. In larger quantities it occasions inflammation, delirium, stupor, coma, death.

Alcohol is used externally as a stimulant in muscular pains; it has lately been discovered to be an useful application in the cure of burns. Internally it is seldom employed; in without dilution; and then is rather administered as an auxiliary, or solvent of other ingredients.

Ether. Ethers bear some resemblance in their medicinal powers to alcohol: they are more diffusible, and less permanent in their operation. They are employed principally in asthma, hysteria, and other spasmodic affections. Their dose is one drachm to one or two drachims. Externally applied, sub- limed alcohol has been used to relieve spasmodic contraction of the muscles, and is often supposed as a substitute for the temples in headache.

Camphora, aulos camporum (Linn.): benzoin, Japan, India. Camphor is a permanent principle of vegetables; it is principally obtained from the aulos camphorum of Japan. In a moderate dose camphor is stimulant; in a larger quantity it invariably diminishes the perspiration of the circulation, and induces sleep.

Camphor has been used as a stimulant in typhus, cyananche maligna, and other affections attended with debility and irritation; as a sedative in pneumonia, rheumatism, &c. In asthma it has been given as an anodyne. As an antispasmodic it is employed in asthma, St. Vitus's dance, and epilepsy. Its dose is from live to twenty grains. Externally, in combination with oil or lanolin, camphor has been advantageously used in rheumatism, bruises, and other inflammatory affections.

Papaver somniferum, poppy, Europe. Asia. The concrete juice of the capsule of this plant is opium, which is chiefly imported from Egypt, Turkey, and the East Indies.

The effects of opium, as above stated, are stimulating: it often occasions, when given in somewhat large doses, intoxication, and even actual delirium. If a larger dose be given, the symptoms of diminished action appear without any previous excitement, and are succeeded by delirium, stupor, stertorous breathing, convulsions, and death.

Where opium is given as a stimulant it ought to be administered in small and frequently repeated doses. Where the intention is to alleviate pain, or to bring on, on the contrary, to be given in a large dose, and at distant intervals. It is of importance to observe, that where evacuations have been previously procured, or when a state of diaphoresis is present, opium is much more gen- eral and salutary than while the skin is dry, or the bowels torpid.

In continued, as well as intermittent, fevers, opium is given as a stimulant. In the profuse of Dr. Cullen, opium is employed to diminish the discharge. In gout it is highly serviceable. In convulsive and spasmatic affections it is often administered to a very great extent, as in the terrors of warm climates. In lues venerea it is thought to accelerate the action of medicine, and is often given to promote suppuration, and is extremely efficacious in arresting gangrene. In the form of enema opium is often administered in violent affections of the bowels.

Its usual dose is one grain to an adult.

Hypocypreus niger, indigenous, herbs, se- men, black hemlock. This plant, in its action on the system, bears a considerable resemblance to opium; for it is often employed as a substitute. The latter is seldom employed as a substitute for its inferiority, occasioning unpleasant sympotms. It is free from the constipating effects of opium.

Atropa belladonna, indigenous, deadly
nightshade. Both the leaves and berries of this plant, and also its root, are narcotic. It is seldom used in medicine.

Aconitum napellus, aconite, monk’s-hood, herb. Europe, America. Aconite has been employed in obstinate chronic rheumatism, in sciatica, &c. Its dose is from one to two grains of the powdered ed leaves; of the inspissated juice half a grain.

Conium maculatum, císta, hemlock, folia, senhen, indigenous. This is a powerful narcotic. Like the aconite, it has been used in sciatica and scrophulous affection, as well as in rheumatism. Dose two or three grains of the powdered leaves; one or two of the inspissated juice.

Digitalis purpurea, foxglove, folia, indigenous. Of all the narcotics, digitalis most speedily and certainly diminishes the actions of the system, especially of the arteries. It acts at the same time as a stimulant on the absorbent system; hence its usual duty in dropsy. Lately it has been extensively employed in phthisis, and in the early stages of this disorder with remarkable success. Dose one grain of the powdered leaves, and ten drops of the tincture of the Edinburgh pharmacopoeia, gradually increased.

Nicotiana tabacum, tobacco, folia, America. This is a powerful narcotic. Its extreme activity prevents it from being much used in medicine.

Lactuca vera, strong-scented lettuce, folia, indigenous. From five to ten grains of the inspissated juice, gradually increased, have been given as a narcotic, diuretic, and antispasmodic.

Datura stramonium, thorn-apple, herba, indigenous. This has been used in mania, epilepsy, and convulsive diseases. Dose from one to three grains of the inspissated juice. Arnica montana, leopard’s-bane, flores, radix, &c. Its root has been employed as a substitute for Peruvian bark.

Rhus toxicodendron, yellow-flowered rhododendron, folia, Sib. ria. This has been given in chronic rheumatism and gout.

Rhus toxicodendron, poison-oak, folia, N. America. The dried leaves have been used in palsy. Dose half a grain twice or thrice a day.

Strychnos nux vomica, vomica nut. East Indies. It has been employed in mania, hysteria, &c. Dose five grains twice a day.

Prunus strobus-cerasus, cherry-tree laurel, folia, Europe. This has scarcely been employed in medicine.

OF ANTISPASMODICS. Antispasmodics form a kind of intermediate class between narcotics and tonics. Spasm sometimes arises from local irritation in states of general irritability, and is sometimes occasioned by pure debility. Both narcotics therefore employed and tonics are used as antispasmodics; but there are certain substances which in some measure appear to possess a specific antispasmodic power; these we are now to enumerate.

Muscum, musk, monotis muschifera, South of Asia. Musk is a peculiar substance found in a small sac, situated in the umbilicus in the male of the above animal. Its antispasmodic powers are considerable. Dose from six to twenty grains in the form of the crude; in a solution: it is useful in much smaller quantities in the convulsions of infants from debility. Castor oil, castor, fiber oil. This is a deposition collected in cells near the extremity of the rectum in the beaver. It is much used in hysteria. Dose from ten to twenty grains.

Oxymalle empyreumaticum, empyreumatic animal oil. This is nearly discarded from practice.

Petroleum, a bitumen of a red colour. This was formerly, but is not now, much employed.

Ammonia. This, when employed alone as an antispasmodic, is given in the form of carbonate.

Ferula assafizida, assafetida, Persia. This is a concrete juice, obtained by incision from the roots of certain plants. Its dose, as an antispasmodic, is from five to twenty grains.

Segrega leucodendron, Persia; virtues the same as assafetida, but inferior in power.

Bubon galbanum, gummi-resina, Africa. Dose ten grains.

Valerian officinalis, wild valerian, radix, &c. Its root is one of the principal antispasmodics. Dose from one scruple to one drachm, three or four times a day.

Coccus arctis, saffron, indigenous. This substance is derived from the stigmas which crown the pistil of the flower. It has scarcely any virtue.

Melancholia levendendron, cajuput oil, India. This is scarcely in use, except as a local application in tooth-ache.

OF TONICS. This term ought not perhaps to be retained. The agency of tonics is not that of increasing tension or tone, but they are permanent stimuli to the system, and are properly regarded as slow and durable, in opposition to the more diffusive and transient stimuli. They are chosen from the mineral and vegetable kingdom; the former are less speedy and sensible in their action than the latter.

From the mineral kingdom.

Hydrargyrum, argentum vivum, mercury. Ferrum, iron. Zincum, zinc. Cuprum, copper. Arsenicum, arsenic. For the various preparations and medicinal virtues of the above important minerals, consult the articles Pharmacy and Medicine.

Boraces, terra ponderosa, heavy earth. This has only been used as a saline combined with muriatic acid. Dr. Crawford introduced the saturated solution into practice as a remedy for scrofula. Dose from five to twenty or more drops.

Calis, lime. This earth exists in nature as a carbonate: when dried, it has been used as a tonic in combination with muriatic acid.

Acidum nitricum, nitric acid. This acid has been used as a tonic to support the system under a mercurial course. It has likewise been used with digitalis and indomitable success, as a specific in the cure of hectic fevers.

Oxymuriatic potassae, oxymuriate of potash. This may be classed as a remedy with the former article. Its dose when grains increased to twenty or twenty-five.

Tonics from the vegetable kingdom.

The tonic faculty in vegetables is intimately united with certain sensible qualities, with astrignency, and with aromatic. The aromatic principle is more active, but less permanent in its stimulating operation. The purest bitters independently possess a tonic power. Astrignency, when it exists exclusively, or as the most predominant principle in vegetables, constitutes a distinct class; the remaining tonics may be arranged according as bitterness or aroma is predominant.

Cichorium intybus, chicory, Peruvian. Cortis, America, Peru. Three kinds of this bark are in use, the pale, red, and yellow. The last is now principally employed, as it gives out more bitterness and astrignency to water, alcohol, and other media. Peruvian bark was first employed in intermittent fever. It has been given in the dose of a scruple or half a drachm every third hour, during the interval of the paroxysm. In continued fever it is principally employed during the latter stages, when debility is severe. In chronic Cases of scrofula, leucodendron, bronchitis, and almost all asthmetic disorders, it has been administered as a tonic.

Cinchona Carthaya, Caribean bark, Caribee islands. Augustae, Spanish West Indies. This herb bark has both been used as substitutes for the Peruvian bark.

Aristolochia serpenaria, Virginia snake-root. This is a stimulating aromatic tonic. It is generally given in the form of tincture. Dose: ten graminea, conserva, cortex, Peru, West Indies. This is scarcely possessed of any virtue.

Croton elethérius, cascarilla cortex, N. America. This is another substitute for Peruvian bark. Dose a scruple or half a drachm.

Colombia, radix, Ceylon, a very useful tonic bitter. Dose half a drachm.

Zinzanex excelsa, lignum, West Indies. This is one of the most excellent aromatic tonics. Dose in substance, from two to thirty grains, thrice a day.

Zinzanex sinuovum, simartobus, cortex, South America. This has been extolled as a remedy in dysentery, and chronic diarrhoea. Dose: ten graminea, conserva, cortex, East Indies. Swietienia mahagoni, mahogany. Two other proposed substitutes for the Peruvian bark.

Gentiana tinctoria, gentian, Switzerland, Germany. This is a common and useful remedy in dyspepsia; its virtues are extracted both by water and spirit. Dose in substance half a drachm.

Antheia nobilis, chamomile, flores, indigenous; a powerful and well-known bitter. N. B. The following plants are now not used in medicine: Artemisia absiníthium, wormwood; Chrysanthemum cynanthus, marigold; Vernáculo vulgaris, borage; Menthae verticillata, mint; Centaurae, blessed thistle.

AROMATIC.

Citrus aurantium, orange, cortex flavus. The rind of the orange is principally employed in tinctures, in combination with different substances used in dyspepsia. It is given in the form of tincture, conserve, and syrup.

Citrus medicus, lemon, cortex fructus,
MATERIA MEDICA.

Asia; similar in flavour and virtue, but rather less bitter than the orange.

Laurus cinnamomum, cinnamon, cortex, Ceylon. This is the most grateful of the aromatics.

Laurus cassia, cassia, cortex, East Indies. This nearly resembles the cinnamon in appearance, taste, and virtue. It is therefore used with the same intention as this last. Its flavour, however, is less grateful.

Canthi alba, cortex, West Indies. This is a moderately strong aromatic: it is not much used except in combination with other substances in the form of tincture.

decoctus cumulatus, sweet-scented flag, radix, indigenous. This is scarcely at all employed in medicine.

Annona squamosa, ginger, radix, East Indies. The dose of ginger is about ten grains.

Kempferia rotunda, zedoary, radix, East Indies. This is seldom employed in medicine.

Santalum album, yellow sanders, lignum, E. Indies. This wood is now nearly banished from practice.

Santalum santalilium, santalum rubrum, red sanders, lignum, India. This, although slightly aromatic, is at present merely used in pharmacy as a colouring ingredient.

Myristica macranta, India. Under the old name myristica, both nutmeg and mace are included: the former is the seed, or kernel of the fruit; the latter its capsule. Nutmeg is given as an aromatic in doses of from five to fifteen grains. In larger doses it is narcotic. Mace is employed for the same purposes as nutmeg.

Carophyllus aromaticus, clove, flores, India. Cloves are the unexpanded flowers of the plant. Dose from five to ten grains.

Capsicum annuum, capsicum, Guinean pepper, fructus, and W. Indies. This fruit is a very powerful stimulant. It is not in much use as a medicine. Dose from five to ten grains.

Piper nigrum, black pepper, fruit, India. Black pepper is the ripe berry of the same vegetable, freed from its outer covering. It is milder than the black. Dose ten or fifteen grains.

Piper longum, long pepper. This is the berry of the plant, gathered before it is fully ripened. It is similar to the black pepper in its qualities.

Piper Cedea, cedibis, the dried fruit of the tree. It has similar virtues to the other peppers.

Myrista pimenta, Jamaica pepper, bacca, W. Indies. This is usually called pimento; it is employed in medicine principally on account of its flavour.

Annona repens, lesser cardamon, semen. Cardamoms form an ingredient in many of the bitter tinctures.

Curcuma caran, caraway, semen, indigenous. These are in common use, in culinary as well as medicinal preparations.

Coriandrum sativum, coriander, semen. These are used with the same intention as caraway.

Pimpinella anisum, anise, semen. Anise is used chiefly in the flatulence of children. The four following seeds have similar virtues to the anise and caraway: Anethum falciporum, falciporum, Anethum graveolens, dill, semen.

Anchusa urticae r우, bear's whortle-berry, folia, Europe. This has been principally given in disorders of the urinary organs. Recently it has been proposed in pleuritis pulmonalis.

Mimosa echinata, catechu, or Japan earth, East Indies. This is a useful and useful astringent in diarrhoea. Its dose is from fifteen to thirty grains. Kino is employed with the same intention as catechu. Its dose is from twenty to thirty grains.

Pterocarpus dioica, dragon's blood, resin, South America. This is scarcely employed in medicine.

Loco, lac, ficus indica, resin, East Indies. Lac is very little employed as a medicinal.

Pistacia lentiscus, mastich, resin, South of Europe. This is likewise discarded from practice.

Astringents.

Astringents are those substances that restrain morbid evacuations. Their mode of operation has been erroneously supposed similar to that by which dead animal matter is constricted and congealed. Increased evacuation do not depend merely upon mechanical laxity of the solids; the process, therefore, by which they are arrested, cannot entirely be ascribed to chemical principles; although in some cases medicines which are employed for this purpose discharge, necessarily possess a power of constringing dead animal fibre. This faculty in vegetables is denominated astringency, and results from the union of gallic acid and tannin principle combined; the former, when separated, is distinguished by its property of striking a deep-black colour with the salts of iron; the other by its great attraction to animal gelatin. Vegetable astringents then may be considered as mere permanent stimuli, modified in their action, even on living matter, by the principle above alluded to. Inordinate evacuations are, however, often restrained by mineral as well as vegetable substances, and in this case the former deserve to be arranged in the class of astringents, according to the definition above given of these powers.

Of Astringents.

Astringents are employed in the treatment of ulcers, hemorrhages, and diarrhoea.

Succus eucomi, cortex, indigenuous. This has been employed in haemorrhage, diarrhoea, and intermittent fever. Its dose in powder is from fifteen to thirty grains.

Succus cerris, galla, south of Europe. These are theerences found on the branch of the tree which produces them. They are employed in medicine for the same purposes, and are used under the same forms, as oak bark.

Tormilla cretica, tormentil, radix, indigenuous. This has been used in diarrhoea in decoction. Its dose, in substance, is from half a drachm to a drachm.

Pilagnum bistorta, bistorta, radix, indigenuous. This is a strong astringent. Dose a scruple to a drachm.

Anchusa tinctoria, alkanet, radix, South of Europe. This is at present merely employed as a colouring matter.

Hematoxylon Campechianum, woodgum. It is used as an astringent under the form of decoction, or watery extract.

Rose gallica, red rose, South of Europe.

The principle use of this astringent is in the form of gargle.
Neither this nor the acetate of copper is in much use; they are violent in their operation, and in no respect preferable to milder emetics.

**OF CATHARTICS.**

A discharge of the intestinal contents appears to be occasioned by medicines upon a twofold principle. Cathartics either immediately act upon the intestines, thus accelerating their peristaltic motion, and consequent fecal evacuations, or they produce this effect more indirectly by stimulating the exhalant and secreting vessels, whose fluids, pancreatic juice, and intestinal mucus act as solvents to, and promote the discharge of, the faces. These latter are milder in their operation than the former: they are classed by Dr. Darwin among the secernentia. There are, however, many drugs which act at the same time in each of the above modes.

Cathartics, still more than emetics, are extensively employed in medicine, as capable of modifying impulses throughout the system. Their use has recently been brought more systematically into notice. Upon the grounds just stated, cathartics may with some propriety be divided into purgatives and laxatives.

**Purgatives.**

**Cassia acutia.** Seed, folia, Egypt, Arabia. This is frequently employed: it is given in the form of infusion. Dose a drachm or more.

**Rheum officinale.** Rhubarb, Tartary. The best rhubarb is imported from Turkey. The China rhubarb has less of the aromatic flavour. British rhubarb is much inferior to either. The dose of rhubarb, as a cathartic, is from fifteen grains to two scruples. It is given with advantage in diarrhoea and dysentery, as it contains an astringent principle. In small doses it is atoxic and tonic.

**Convolvulus Jalapa.** Jalap, radix, Mexico. This is often administered both alone and more especially with calomel (submuriac hydargyri). Its dose is from fifteen grains to two scruples.

**Helicteres niger.** Black heliobole, radix, Austria, Italy. This, in a dose from ten to twenty grains, is a violent cathartic. It is seldom employed in modern practice. Dr. Mead attributed a powerful emmenagogue property to it, which however has scarcely been realized by others. The ancient physicians gave it freely in maniacal disorders.

**Bryonia alba.** Buxton, radix, indigenous. This root is not much used. Dose from twenty to thirty grains. It is slightly diuretic.

**Caucasus colocynthis.** Colocynthis, fructus, Syria. This is a much used cathartic in all purgatives. Its dose is half a grain to two grains.

**Rhamnus catharticus.** Buckthorn, beccanum success, indigenous. This is seldom used.

**Also perfoliatum.** Senna, Barbadoes, or hepatic and calamine doses; succus spinatus, Africa, Asia, America.

The cathartic doses is the purest. The Barbadoes and hepatic rank next. The calamine is the most impure, and is the weakest. Dose from fifteen grains to a scruple. Its action is principally upon the later intestines, and on account of the viscid, or water-like, nature of the discharge of these vessels, the uterus, it is often useful in amenorrhoea.

**Cassia fistula.** Cassia, purging cassia, or cassia in the pod; pulpa fructis, Egypt, East and West Indies.

Dose from five to eight or ten grains.

**Laxatives.**

**Mecon.** Manna, fraxinus omus, succus concretus, South of Europe. This is a mild and pleasant laxative. It is frequently given to children in conjunction with senna. Dose to an adult from one to two ounces.

**Cassia fistula.** Cassia fistula, common cassia. Dose from four to six drachms.

**Tamarix indica.** Tamarind, fructus confusus, E. and W. Indies, America, Arabia. The tamarind of the shops is the pulp of the tree mixed with seeds and small fibres, with a quantity of coarse sugar. It may be taken to the extent of two ounces, or more.

**Rhus verniciflua.** Palma Christi, oleum, senna, W. Indies. The oil from the nuts of palma Christi is the castor oil of the shops. This is a mild and very useful purgative.

**Sulphur.** A simple inoffensive substance, and magnesia, either pure orcarbonated, are all the laxatives that are afforded by the mineral kingdom. The operation of either is exceedingly mild.

For the different neutral salts that are employed as purgatives in medicine, see Pharmacy.

The purgatives that are administered only in the form of enema, are the

**Terebuthinae crestum.** Turpentine, pinnaria larica, gymnium-resina. This is sometimes employed as an enema triturated with the yolk of an egg. Dr. Cullen recommends this as a very certain cathartic. It is indicated in obstinate constipation.

**Nicotiana.** The introduction per-ann of tobacco smoke has sometimes been effectual in procuring alvine evacuation, after other cathartics have failed. The infusion of one or two drachms in a pint of water is a more convenient mode of administering this medicine. Much caution is requisite in either case to obviate its injurious effects.

**OF EMENAGOGUES.**

These are medicines which promote the menstrual discharge. Obstruction or reten-
MATERIA MEDICA.

 tion of the menses, unless consequent upon defective conformation, or uterine impregna-
tion, is usually owing to weakness or want of due excitation in the vesicles of the uterus. This
deficiency is best overcome by gen-
eric remedies, or by taking a decoction of the leaves of some
myrrha, three drachms being given, to which
these virtues, which action is principally directed to the in-
ferior portion of the intestinal canal. In this
of the function of some
ferum, the carbonate of iron, rubigo
ferri praeparata; is given in a dose of ten or
fifteen grains in ammoniacum, the sulphate of
iron in three or four grains. This is the
ferrum vitriolatum of the London pharma-
copoeia.

Hydargyrus, the mild mutirite of mer-
cury, as already noticed.

Sanguis organicum. This is "frequently given" in
ammoniacum, in conjunction with some of the preparations of
iron.

From the class of antispasmodics. Castorium. This is a medicine of very
trilling efficacy when used as an emmen-
gogue. Dose from ten to twenty grains.

Ferula assyriatica, and the other fett
grains, (galbanum, sagapenum, and ammoni-
acum) are employed sometimes as emmen-
gogues. Dose from ten grains to fifteen.

From the class of cathartics. Aloe. This is a substance generally con-
nected with others when given to promote
the menses, as in the pilula aloe cum
myrrha, &c.

Helieborus niger. This is not at present
in much repute. Dose of the extract from
three to ten grains.

Sinapis alba, semen, mustard-seed in the
dose of about half an ounce is sometimes
taken as an emmenagogue.

Chelidonium officinale, rosemary, sum-
mittales florentis. This is now nearly banish-
ed from practice.

Rubia tinctorum, madder, rhizis, south of
Europe. A dose from a scruple to half a
drachm. Its virtue is not much confined in
by modern physicians.

Ruta graveolens, ruta, rue, herba, south
of Europe. The herb in the form of infu-
sion, and likewise its essential oil, are the
preparations of rue that are given. It is per-
haps of inferior efficacy.

Juniperus sabina, savin, folia, south of
Europe. Savin is not much used internally,
although supposed by some to be a powerful
emmenagogue.

OF DIURETICS.

Diuretics are those medicines which aug-
ment the urinary discharge. This effect is
either produced by a direct stimuli on com-
municated to the kidneys, by a sympathetic
excitation of these organs from a product of
deton action excited in the stomach, or, lastly,
by the promotion of absorption, by which more
than their usual quantity is directed to the
secretory vesicles of the urine. The saline
drugs are principally so exert their agency in the first of these ways. Squill
and others appear to produce a primary ac-
ction of the stomach, and digitalis from its
extraordinary power over the absorbent sys-
tem is an example of the last-mentioned
mode of procuring diuresis.

Saline diuretics.

Superius pain, cream of tartar.
Dose four or six drachms twice a day in
considerable quantities of water. This has
been much employed in dropsy.

Nitros potassus, nitre. Dose from five to
twenty grains. Nitre was formerly much
used in gonorheea, in order to abate the
ardor urinæ.

Muriros ammoniaci, crude salt ammoniac.
This is not much employed. Dose from
eight grains to a scruple.

Aceti potassii, sal diuretis. This has
now likewise fallen into disuse.

Potassa, kali. The dose of carbonated
kali is from twenty to thirty grains.

Vegetable diuretics.

Scilla maritima. Dose as a diuretic from
one to three or four grains.

Digi dias purpurea. Dose from one grain
to two or more, of the powdered lea:
from ten to thirty drops of the saturated
tincture. The dose requires to be regulated
and increased with the degree of

Nicotiana tabacum. An ounce of the
dried leaves infused in a pint of water, has
been given as a diuretic in the dose of from
sixty to a hundred drops.

Solanum dulcamara, poisonous, nightshade,
bitter, sweet, indigenous. This is scarcely
ever prescribed.

Lactua verona. Dose from ten grains to
three drachms. It is not much used.

Cochlearia officinalis, medicow saltnum, indi-
genous. This has not been in much use
in this country. It was first prescribed in
dropsy by Storck of Vienna.

Gratiola officinalis, hedge hyssop, south of
Europe. The leaves of this plant have
likewise been given in dropsy, but they have
not come into general use.

Spartium scoparium, broom, summittales,
indigenous.

The broom tops infused in water have
proved advantageous in dropsy.

Juniperus communis, juniper, bacca indi-
genous. Juniper berries given in infusion
have a pretty considerable diuretic power.

Copaeiia officinalis, copaera balbus,
South America. Dose from twenty to thir-
ty drops twice a day. It is principally em-
ployed in gleet.

Pinnas ovalis, Venice turpentine, holms
Dose from five to twelve drops of the essen-
tial oil. This has likewise been given in
gleet, and in sciata.

Pisctia teres, English turpentine, the
common turpentine (pinus sylvestris balbus)
is on the other hand the most offen-

Diuretics from the animal Kingdom.

Melis vestitiiria, cantharides, Spanish
fly. This is an insect collected from the
leaves of plants growing in the South of
Europe. It has principally been given in
to the secretion of the bladder, and in the
retention of urine. Dose one grain gradually
increased.

OF DIAPHORETICS.

If the natural and constant exhalation
from the skin be condensed on the surface
from its augmented discharge, it constitutes
sweat. This effect when produced only to a
certain extent, is called diaphoresis. Di-
aphoretic and sudorific powers differ then
only in degree. Diaphoresis is chiefly by
Darwin under the head of secretinaria. They
are necessarily operate by directly or indirectly
exciting the cutaneous exhalations. The sa-
line and cooling diaphoresis appear to act
better, the hot and dry medicines which
are given to procure sweat in the former
manner. Diaphoresis with respect to their
influence on the system, are often abun-
dantly powerful and salutary.

Antimony. All saline preparations are
more or less diaphoretic under proper regu-
lation. The ammonial salts have been
imagined to be so in a greater degree than
others. See Pharmacy.

Hydragyrum. The mild muricate (calo-
iac) in conjunction with opium is very
small doses, is sometimes usefully employed
as a diaphoretic.

Antimonius. All the preparations of
antimony may be made to prove sudorific.

Pergamini. In a dose of two or three
drops or without caution, is considered as
intended as a diaphoretic.

Guacon officinalis, guaiac ligurnum, et
guani-resina, South America, and the West
Indies. Guaiac wood is given in the form
of infusion, and the gum which is given in
the course of the day. The gum-resin is
commonly administered in spirit of amberine,
in which it derives a considerable part
or its virtues. Dose from one draught to two
of the tincture.

Daphne mezereum, vevren, cortex ra-
dicis indigena. This is a stimulating di-
aphoretic; it is generally given in views of
inflammation of the liver, and of gout, forming the Liveridge's

Sinae sarcoverpa, radix, South America.
This has scarcely any power exclusively
employed.

Anis, sassafras, sassafras, ligurnum, Ameri-
ca. This is slightly stimulating and dia-
phoretic. It is probably less efficacious than
this has generally been imagined.

Cucullaria armoracia, horse-radish, radish,
indigenous. This is a stimulant capable of
promoting perspiration. About a draught
of the root cut in small pieces and swallowed
whole, has been recommended in paralysis,
reumatism, asthma, and dropsy.

Salvia officinalis, sage, folis, South of
Europe. Its aqueous infusion drunk warm
is slightly stimulating and diaphoretic.

EXPECTORANTS.

Are those medicines which facilitate the
rejection of mucus or other fluids from the lungs. This object is accomplished by
inspiring the pulmonary viscidia, where the
sufficiency, or diminishing it when too copious.

In the one instance expectorants are sec-
vent, in the other absorbent powers; their
operation, like that of emetics, is in both
cases the same. See Pharmacy.

Antimonius. The most common prepa-
rations of antimony for an expectorant is the
cutaneous tartar of the shops. This is given in
**MATERIA MEDICA.**

The juice of the lemon is composed of citric acid, and saccharine and mucilaginous matter. It is the most powerful and agreeable of the refrigerants. With carbonate of potash, it forms the draught, the virtues of which are perhaps owing to the carbonic acid that is evolved by the mixture of the acid and alkali.

**Antacids.**

These are perhaps more strictly chemical in their primary operation than the last class of medicines. They immediately neutralize the prevailing morbid acidity of the stomach.

**Alkalies.**

Pure potash in solution is employed to correct acidity, in doses of fifteen drops in water. The carbonates of potash and soda are, however, in more general use for this purpose.

**Aqua ammonio.**

This is given likewise with this intention. Dose from twenty to forty drops.

**Aqua calis.**

Lime-water is also used to correct acidity; six or eight ounces being taken occasionally.

**Carbonas calcis.**

Of these there are two varieties, creta alba, (prepared chalk) and chelae cancerum (crab's claws). These, especially the former, are principally used in the diarrhoea of infants.

**Magnesia (carbonas magnesia).**

This in some cases preferable to chalk as an acid, as the neutral compound formed by its union with the acid of the stomach proves slightly purgative.

**OF LITHOTRIPSES.**

Medicines supposed to have a power of dissolving stone in the bladder. Calculus is principally formed by a peculiar acid, called the lithic acid, which alkalies unite out of the body, and thus become part of the stone. These medicines, however, cannot in any way be conveyed to the urinary organs in sufficient quantity to effect this purpose without material injury to the parts and the general system. It has, indeed, been ascertained, from experiment, that by the exhibition of alkaline substances, for a length of time, the constitutional disposition to secrete fresh calculi is in a great measure obviated. These substances are rather preventive than curatives of calculary disorders. That they do not, when taken into the stomach, operate as solvents, is sufficiently evident, from the circumstance of their being more useful when administered saturated with carbonic acid; for these alkaline carbonates do not exert any action on the urinary calculus out of the body, as the lithic acid of the calculus is not of sufficient attractive power to disengage the carbonic acid from its union with the salt. The only power then that is possessed by the medicines termed lithotriptes, is that of neutralizing acidity in the first passages, and thus preventing the deposition of lithic acid in the urinary organs.

**Potassae, potass.** The dose of the solution...
of pure potash is 15 or 20 drops gradually increased. The form in which it is generally employed is as a labyrinth, is in the supersaturated solution. Does, one or two pounds daily.

Soda. This is likewise used in the form of saturated solution, under the name of soda water. Does, one or two ounces in the course of the day.

Galls. Lime-water is sometimes employed as a lithotriptic.

DEULCENTS

Are substances employed in medicine to shield from astringency; they can only act on the parts to which they are directly applied. From some circumstances, however, attending their internal administration, it is supposed that they are capable of being absorbed and again separated by particular secrerary organs. This supposition does not appear to be satisfactory.

Astragalus officinalis, gum arabic, Africa. This is used to allay the irritation of the fauces in catarrh. It is likewise given in tenesmus, strangury, &c.

Antirrhinum tragacantha, tragacanth, South of Europe, Asia. This has virtues similar to gum arabic. It is more viscous.

Linum usitatissimum, flax, semen, indigenuous. This is sometimes used in gomorrina, and catarrh.

Veratrum album, marsh mallow, radix, indigenuous.

Malva sylvestris, common mallow, folia, indigenuous. This is used in virtue to sago.

Arctium lappa, South America. Arrow-root is demulcent, and slightly nutritive.

Trifolium hybernum, wheat, amylin. Starch is useful as an enema with opium in dysentery, &c.

Copa vitrea, blosson, indigenuous. Similar in virtue to sago.

Maeruia aromatica, South America. Arrow-root is demulcent, and slightly nutritive.

MATRICE, or Matrix, in dyeing, is ap-
Matric, or Matrics, See Coining.

Matric, or Mother Earth, the stone in which metallic ores are found enveloped.

Matrosse, or Matrosse (or), which some lexicographers have derived from mater, a mother; denotes, in its primitive sense, that unexplained something from which all those things which are objects of our sense derive their being.

The term body is sometimes confounded with that of matter; but they are essentially different. Body is of Saxon origin. It is explained by the Latin words statura, pectus, truncus, and hostia, or the Latin name of a man, or other creature; whence it is plain that it ought to be confined to express a substance possessing form or figure.

Substance, both in its etymology and application, is the inherent essence to the meaning of the former of these terms. It is well known to be compounded from the Latin proposition sub (under) and the verb stare (to stand). It consequently implies that which supports or stands under the different forms and appearances which are presented to our senses. It is still, however, used in a distinct and more limited sense than matter. It is generally indeed used with the article, to signify a distinct or definite portion of matter; whereas matter in the abstract implies a more confused and general idea of solidity and extension, with little or no regard to figure, proportion, or quantity.

That the same matter of which this universe of things is composed, is essentially the same, and that the apparent differences which subsist in different bodies depend altogether on the particular distribution or disposition of the component particles, is an opinion which has been entertained by some philosophers of the highest reputation. The wonderful apparent transmutations which take place in the different processes and operations of nature can be confessed, at first sight countenance this hypothesis. A plant will vegetate, and become a solid substance, in the purest water. The generation of stones in earth, the various phenomena of petrifications, and a multitude of other facts, contribute greatly, on a fair consideration, to diminish the absurdity of the alchemists (who seem chiefly to have rested on this hypothesis) that all matter was essentially the same and the basis of its conversion the same materials by the efforts of art into the most splendid and valuable of substances.

Mr. Boyle dissented the same water about two hundred times, and at the end of each distillation found a fresh deposit of earth. Magriff repeated the experiment with still greater caution. By means of two glass globes, which communicated with each other, he preserved the water while in the state of vapour from all contact with the air; and on repeated distillation, a quantity of earth of the calcareous kind was deposited at the conclusion of each operation.

The extreme rarity and minuteness of the particles into which different substances may be resolved, imparts a still greater degree of probability to this hypothesis; and in general the more any body can be divided, the simpler it appears in its component parts.

We must, however, be cautious of admitting opinions which are not sanctioned by the direct test of experiment; and however plausible the opinion, the accurate observations of modern philosophy have suggested some objections to the homogeneity of matter, which, without further discoveries, it will not be easy to silence.

Whatever phenomenon may appear to indicate a transmutation of bodies, or a change of one substance into another, we have the utmost reason, by the latest and best experiments, to believe them merely the effect of confusion, and of the conversion of air and water into a solid substance, such as the body of a plant, is merely an apparent conversion; for that solid substance may, by an artificial process, be resolved again into its original particles or elements. In the evolution of the principles or elementary particles of which those fluids are composed; and the formation of stones, and the phenomena of petrifications, are accounted for upon much easier principles, and with greater precision.

On the other hand, the utmost efforts of chemistry have never been able to proceed farther in the analysis of bodies than to reduce them to a few principles, which appear essentially different from each other, and which have never yet been brought to a more simple form. Thus the matter of fire, or light, appears totally different from that of all other bodies; thus the acid and alkaline principles cannot be brought under the same properties; nor can even the different species of earth be converted into the substance of each other.

If hypothetical reasoning was to be admitted on this occasion, it would appear more agreeable to the analogy of nature, to suppose that different substances are formed from the different combinations of a few simple principles in different proportions, than that the very opposite qualities of some of the rarest and most subtle fluids should depend wholly on the different form or modification of the extremely minute particles which enter into their composition.

Whatever distinction it may be proper to observe, that on this subject there has hitherto appeared no decisive experimental proof on either side. The imperfection of all human efforts, and perhaps of the human faculties themselves, has hitherto confined our investigations to the properties of a few substances, the simplest which chemical analysis has been able to obtain, and which for that reason are denominated fundamental. See Elements.

Mazzuchelli, Filippo, author of the tetrads monographia class and order. The calyx is four-parted; corolla one-petalled; germ superior, four-lobed. There is one species, a herb of Guiana.

Mauritia, the grilgo, or mainau-hair, a genus of plants belonging to the natural order of palm. The calyx of the male is monopetallous; the corolla monanepetalous, with six adnate. It is a native of Japan, where it is also known by the names of man and fasia. It rises with a long, erect, thick, and serrated stem, to a palm-tree. The bark is ash-coloured, the wood brittle or smooth, the pith soft and spongy. The leaves are large, expanded from a narrow bottom into the figure of a mainau-leaf, unequally parted, streaked, without veins or nerves. From the uppermost shoots hang the flowers in long catkins that are filled with the fertilizing power; and to which succeeds the fruit, adhering to a thick fleshy pedicle, which proceeds from the bottom one or two, this fruit is either exactly or nearly round, and of the appearance and size of a camphor plum. The substance surrounding the fruit is fleshy, white, very hard, and adheres so firmly to the enclosed nut, as not to be separated from it except by putrefaction. The nut, properly termed gineau, resembles the pista-chio nut, especially a Persian species named bergies pistio; but is almost double in size, and of a rounder figure or oval. The shell is somewhat white, woody, and brittle, and incloses a white bone kernel, having the sweetness of an almond, along with a degree of hardness. These kernels taken after dinner are said to give to the inclosed nut, as not to be separated from it except by putrefaction. The nut, properly termed gineau, resembles the pista-chio nut, especially a Persian species named bergies pistio; but is almost double in size, and of a rounder figure or oval. The shell is somewhat white, woody, and brittle, and incoses a white bone kernel, having the sweetness of an almond, along with a degree of hardness. These kernels taken after dinner are said to give to the inclosed nut, as not to be separated from it except by putrefaction.

Maxilla. See Anatomy.

Maximum, in mathematics, denotes the greatest or most considerable in any given case. If a quantity conceived to be generated by motion, increases, or decreases, till it arrives at a certain magnitude or position, and then, after passing it, decreases, or becomes greater, and it be required to determine the said magnitude or position, the question is called a problem de maximum et minimis.

Thus, let a point move uniformly in a right line from one extremity and let another point move after it, with a velocity either increasing or decreasing, but so that it may, at a certain position D, become equal to that of the former point, moving uniformly.

D

B a

This being premised, let the motion of n be first considered as an increasing one; in which case the distance of n behind m will continually increase, till the two points arrive at the contemporary positions C and D; but afterwards it will again decrease; for the motion of n till then being slower than at D, it is also slower than that of the preceding point m (by the postulate), but afterwards, whatever after the point m (as has been already said) will again decrease; and therefore is a maximum, or the greatest of all, when the velocities of the two points are equal to each other.
that of $n$, its fluxion at that instant is evidently equal to nothing. Therefore, as the motion of the points $m$ and $n$ may be conceived such that their distance $mn$ may express the measure of any variable quantity whatever, it follows, that the fluxion of any variable quantity whatever, when a maximum or a minimum is, equal to nothing.

The rule therefore to determine any flowing quantity in an equation proposed, to an extreme value, is: having put the equation when it is found, let the fluxion of that quantity whose extreme value is sought be supposed equal to nothing; by which means all the members of the equation in which it is found will vanish, and the remaining ones will give the determination of the maximum or minimum required.

Prob. I. To divide a given right line into two equal parts, that their product, or rectangle, may be the greatest possible. This is the case when the line is bisected or divided into equal parts. See Fluxions.

In any mechanical engine the proportion of the power to the weight, when they balance each other, is found by supposing the engine to move, and regarding their velocity as proportional to the respective directions in which they act; for the inverse ratio of those velocities is that of the power to the weight according to the general principle of mechanics. But it is of use to determine likewise the proportion they ought to bear to each other, that when the power prevails, and the engine is in motion, it may produce the greatest effect in a given time. Therefore, the weight moves at first with an accelerated motion; and when the velocity of the power is variable, its action upon the weight decreases, while the velocity of the weight increases. Thus the action of a stream of water or air upon a wheel, is to be estimated from the excess of the velocity of the fluid above the velocity of the part of the wheel which it strikes, or from their relative velocity only. The uniform motion of the engine ceases to be accelerated when this relative velocity is so far diminished, that the action of the power becomes equal to the resistance of the engine arising from the gravity of the matter that is elevated, or from friction; for while the velocity balances each other, the engine proceeds with its uniform motion it has acquired.

Prob. II. Let $a$ denote the velocity of the stream, $s$ the velocity of the part of the engine which it strikes when the motion of the machine is uniform, and $a - s$ will represent their relative velocity. Let $A$ represent the weight which would balance the force of the stream when its velocity is $a$, and $a - s$ the weight which would balance the force of the stream if its velocity was only $a - s$; then $\rho = A \times \frac{a - s}{a}$, and $\rho$ shall represent the action of the stream upon the wheel. If we subtract the friction, and have regard to the quantity of the weight only, let it be equal to $\Delta w$; (for we have $\Delta w = \rho \times \Delta y$), and because the motion of the machine is supposed uniform, $\rho = \frac{a}{\Delta y}$.

\[ x \times a^{n} = \text{vanishes}, \text{that is, when } x \times a^{n} = \text{vanishes} \]

\[ \frac{\Delta w}{a} = \frac{a}{\Delta y} \times \frac{a}{a} \]

The momentum of this weight is $\frac{\Delta w}{a}$, which is a maximum when the fluxion of $x \times a^{n}$ vanishes.
The MEAN PROPORTIONAL, between two given lines, is the line which at the same time is to the lesser as the greater is to the sum of the lesser and the greater.

Thus, if the squares on a and b be equal, a and b are in mean proportion; and the mean proportional between a and b is \( \sqrt{ab} \).

This proportion is especially useful in the solution of quadratic equations.

Example: To find the mean proportional between 4 and 9.

\[ \sqrt{4 \times 9} = \sqrt{36} = 6 \]

Therefore, the mean proportional between 4 and 9 is 6.

The mean proportional is also used in the calculation of the sides of a rectangle when the area and one side are known.

Example: If the area of a rectangle is 25 square units and one side is 5 units, the other side can be found as follows:

\[ \sqrt{25} = 5 \]

Thus, the other side is also 5 units, making the rectangle a square.

The mean proportional is also used in the calculation of the altitude of a triangle when the base and area are known.

Example: If the area of a triangle is 12 square units and the base is 6 units, the altitude can be found as follows:

\[ \sqrt{\frac{2 \times 12}{6}} = \sqrt{4} = 2 \]

Thus, the altitude of the triangle is 2 units.

The mean proportional is also used in the calculation of the diameter of a circle when the circumference is known.

Example: If the circumference of a circle is 10 units, the diameter can be found as follows:

\[ \sqrt{\frac{10^2}{\pi}} = \sqrt{\frac{100}{\pi}} \]

Thus, the diameter of the circle is approximately 3.18 units.

The mean proportional is also used in the calculation of the volume of a sphere when the surface area is known.

Example: If the surface area of a sphere is 40 square units, the diameter can be found as follows:

\[ \sqrt{\frac{40}{4\pi}} = \sqrt{10} \]

Thus, the diameter of the sphere is approximately 3.16 units.

The mean proportional is also used in the calculation of the speed of a moving object when the distance and time are known.

Example: If an object travels 100 units in 5 units of time, the average speed can be found as follows:

\[ \sqrt{\frac{100}{5}} = \sqrt{20} \]

Thus, the average speed of the object is approximately 4.47 units per unit of time.
3. The Englishavoirdupois pound weighs 7004 troy grains; whence theavoirdupois ounce, whereof to make a pound, is found equal to 437.75 troy grains. And it follows, that the troy pound is to theavoirdupois pound as 88 to 107 nearly; for as 88 to 107, so is 5760 to 7004.536; that the troy ounce is to theavoirdupois ounce, as 80 to 73 nearly; for as 80 to 73, so is 480 to 437.5: and, lastly, that theavoirdupois pound and ounce are to the Paris two-inch weight and ounce, as 65 to 68 nearly; for as 65 to 68, so is 7004 to 7300.767. See Weight 4. The Paris foot expressed in decimals is equal to 1.0054 of the English foot, or contains 12.783 English inches.

3. The standard in Holland, Flanders, Sweden, a good part of Germany, many of the Hanse towns, as Danzick and Hanbourg, and at Geneva, Franchfort, &c. is likewise the ell; but the ell in all these places differs from the Paris ell. In Holland it contains one Paris foot 11 lines, or 4-sevenths of the Paris ell. At Bologna, Modena, and Mantua, the ell is the same as at Venice. At Lucca it contains 1 Paris foot, 9 inches, 10 lines, or 8-fifteenths of the Paris ell. At Milan, the ell is the same as at Venice. At Lucca it contains 1 Paris foot, 9 inches, 10 lines, or 11 sixteenths of the Paris ell. At Florence it contains 1 foot, 9 inches, 10 lines, or 4-hundredths of the Paris ell. At Milan, the ell for measuring of silks is 1 Paris foot, 7 inches, 4 lines, or 4 ninths of a Paris ell; that for wooden cloths is the same as the ell of Holland. Lastly, at Geneva, the ell is 1 foot 7 inches, 6 lines, or 3-ninths of a Paris ell. The usual measure in Naples, however, is the canna, containing 6 feet, 10 inches, and 2 lines, or one Paris ell and 15-seventeenths.

5. The Spanish measure is the vara or yard, in some places called the vara; containing 17 twenty-fourths of the Paris ell. But the measure in Castile and Valencia is the span, or palm; which is used, together with the canna, at Genoa. In Arragon, the vara, is equal to a Paris ell and a half, or 5 feet, 5 inches, 6 lines.

6. ThePortuguese measure is the cavo,

The Piedmontese measure is the ras,

The Muscovite measures are the cubit,

The Turkish and Levant measures are the piey,

The Chinese measure is the cubit, ten whereof are equal to three Paris ells.

For wood:

10,000,000th part of the dist. from the pole to the equator

A decimetre cube.

1 pint and \( \frac{1}{3} \)5, or 1 litre and \( \frac{1}{3} \) nearly.

18 grains and 841,000 parts.

Two square perches
des eaux et forêt.

1 demi-voile, or \( \frac{1}{4} \) of a cord des eaux et forêt.

3. The Englishavoirdupois pound weighs 7004 troy grains; whence theavoirdupois ounce, whereof to make a pound, is found equal to 437.75 troy grains. And it follows, that the troy pound is to theavoirdupois pound as 88 to 107 nearly; for as 88 to 107, so is 5760 to 7004.536; that the troy ounce is to theavoirdupois ounce, as 80 to 73 nearly; for as 80 to 73, so is 480 to 437.5: and, lastly, that theavoirdupois pound and ounce are to the Paris two-inch weight and ounce, as 65 to 68 nearly; for as 65 to 68, so is 7004 to 7300.767. See Weight 4. The Paris foot expressed in decimals is equal to 1.0054 of the English foot, or contains 12.783 English inches.

### Cubical Measures, or Measures of capacity for liquids.

The English measures were originally raised from Troy-weight; it being enacted by several statutes that eight pounds Troy of wheat, gathered from the middle of the ear, and well dried, should weigh a gallon of wine-measure, the divisions and multiples whereof were to form the other measures; at the same time it was also ordered, that there should but one liquid measure in the kingdom; yet custom has prevailed, and there having been introduced a new weight, viz. the avoirdupois, we have now a second standard gallon adjusted thereto, and therefore exceeding the former in the proportion of the avoirdupois weight to Troy weight.
From this latter standard are raised two several measures, the one for ale, the other for beer.

The sealed gallon at Guildhall, which is the standard for wines, spirits, oils, &c. is supposed to contain 231 cubic inches, and on this supposition the other measures raised therefrom, will contain as in the table underneath; yet, by actual experiment, made in 1688, before the lord-mayor and the commissioners of excise, this gallon was found to contain only 230 cubic inches: it was however agreed to continue the common supposed contents of 231 cubic inches; so that all computations stand on their old footing. Hence, as 12 is to 231, so is 14$\frac{3}{5}$ to 282$\frac{3}{5}$ the cubic inches in the ale gallon: but in effect the ale quart contains 70$\frac{1}{2}$ cubic inches, on which principle the ale and beer gallon will be 282 cubic inches. The several divisions and multiples of these measures, and their proportions, are exhibited in the following tables:

MEASUREMENTS FOR HORSES, is the hand, which
by statute contains four inches.

MEATUS AUDITORIUS. See ANATOMY.

MECHANICS, that branch of practical mathematics which considers motion and moving powers, their nature and laws, with their effects in machines.

The term mechanics is equally applied to the doctrine of the equilibrium of powers, more properly called statics; and to that science which treats of the generation and communication of motion, which constitutes mechanics strictly so called. See Statics, Power, Motion, 

The knowledge of mechanics is one of those things, says Mr. Mac Laurin, that serve to distinguish civilized nations from barbarians. It is by this science that the utmost improvement is made of every power and force in nature; and the motions of the elements, water, air, and fire, are made subservient to the various purposes of life; for however weak the force of man appears to be, when unassisted by this art; yet, with its aid, there is hardly anything above his reach. It is distinguished by sir Isaac Newton into practical and rational mechanics; the former of which treats of the mechanical powers, viz. the lever, balance, axis and wheel, pulley, wedge, screw, and inclined plane.

Rational mechanics comprehends the whole theory of motion, shews when the powers or forces are given how to determine the motions that are produced by them; and conversely when the phenomena of the motions are given, how to trace the powers or forces from which they arise.

Mechanical powers are simple engines that enable men to raise weights, to move heavy bodies, and overcome resistances, which they could not do with their natural strength alone. Their importance to society is incalculable. Every machine whatever is composed of one or more of them, sometimes of several combined together.

In considering this science, it will be necessary at first to take some things for granted that are not strictly true; and alter the theory is established, to make the proper allowances.

1. That a small portion of the earth's surface, which is spherical, may be considered as a plane.
2. That all bodies be supposed to descend in lines parallel to each other; for though all bodies really tend to the centre of the earth, yet the distance from which they fall is comparatively so small, that their inclination towards each other is inconsiderable.
3. That all planes be considered as perfectly smooth; levers to be inelastic, and without

three things are always to be considered in treating of mechanical engines; the weight to be raised, the power by which it is to be raised, and the instrument or engine by which this is to be effected.

The mechanical powers are generally reckoned six; the lever, the pulley, the wheel and axis, the inclined plane, the wedge, and the screw.

These perhaps may be reduced to two; for the pulley and wheel are only assemblages of levers, and the wedge and screw are inclined planes.

To calculate the power of a machine, it is usually considered in a state of equilibrium; that is, in the state when the power which is to overcome the resistance just balances it. Having discovered what quantity of power will be requisite for this purpose, it will then be necessary to add so much more as to overcome the friction and weight of the machine itself, and to give the necessary velocity.

The lever is the simplest of all machines; and is only a straight bar of iron, wood, or other material, supported on, and moveable round, a prop called the fulcrum.

In the lever there are three circumstances to be principally attended to: 1. The fulcrum, or prop, by which it is supported, or on which it turns as an axis, or centre of motion. 2. The power to raise and support the weight. 3. The resistance or weight to be raised or sustained.

The points of suspension are those points where the weights rest upon which they hang freely. The power and the weight are always supposed to act at right angles to the lever, except it is otherwise expressed.

The lever is distinguished into three sorts, according to the different situations of the fulcrum or prop, and the power, with respect to each other. 1. When the prop is placed between the power and the weight. 2. When the prop is at one end of the lever, the power at the other, and the weight between them. 3. When the prop is at one end, the weight at the other, and the power applied between them.

A polder, in stirring the fire, is a lever of the first sort; the bar of the grate upon which it rests is the fulcrum; the fuel, the weight to be overcome; and the hand is the power. The lever of the first kind is principally used for loosening large stones; or to raise great weights to small heights; or to get ropes under them, or other means of raising them to still greater heights; it is the most common species of lever.

ABC, Plate Mechanics, fig. 1. is this lever, in which B is the fulcrum, A the end at which

the power is applied, and C the end where the weight acts.

To find when an equilibrium will take place between the power and the weight, in this as well as in every other species of lever, it is necessary to recollect, that when the moments, or quantities of force, in two bodies are equal, they will balance each other. Now let us consider when this will take place in the lever. Suppose the lever AB (fig. 2) to be turned on its axis, or fulcrum, so as to come into the situation DC; the weight B is the farthest from the centre of motion, and as it has moved through the arch AD in the same time as the end B moved through the arch BC, it is evident that the velocity of AB must have been greater than that of B. But the moments being the products of the quantities of matter multiplied into the velocities, the greater the velocity, the less the quantity of matter need be to get the same product. Therefore, as the velocity of A is the greatest, it will require less matter to produce an equilibrium than B.

Let us next see how much more weight B will require than A to balance it. As the radii of circles are in proportion to their circumferences, they are also in proportion to their solids, and Consequently, as the arcs AD, CD, are similar, the radius or arm DE bears the same proportion to EC that the arc AD bears to CB. But the arcs AD and CB represent the velocities of the ends of the lever, because they are the spaces which they moved over in the same time; therefore the arms DE and EC may also represent these velocities.

It is evident then, that an equilibrium will take place when the length of the arm AE multiplied into the power A, shall equal EB multiplied into the weight B; and consequently, that the shorter EB is, the greater must be the weight B; that is, the power and the weight must be to each other inversely, as their distances from the fulcrum. Thus, suppose AE, the distance of the power from the prop, to be 20 inches, and EB, the distance of the weight from the prop, to be eight inches; and if the weight be five pounds, then the power to be applied at A must be two pounds; because the distance of the weight from the fulcrum eight, multiplied into the weight five, makes 40; therefore, 20, the distance of the prop, must be multiplied by two, to get an equal product, which will produce an equilibrium.

It is obvious, that while the distance of the power from the prop exceeds that of the weight from the prop, a power less than the weight will raise it, so that then the lever affords a mechanical advantage: when the distance of the power is less than that of the weight from the prop, the power must be greater than the weight to raise it; when both the arms are equal, the power and the weight must be equal, to be in equilibrium.

The second kind of lever, when the weight is between the fulcrum and the power, is represented by fig. 3, in which A is the fulcrum, B the weight, and C the power. The advantage given by this lever, as before, is as great as the distance of the power from the prop exceeds the distance of the weight from it. Thus if the point 4, on which the power acts, is seven times as far from A as

Q 2
the point b, on which the weight acts, then one pound applied at C will raise seven pounds.

This lever shows the reason why two men carrying a burden upon a stick between them, bear shares of the burden which are to one another in the inverse proportion of their distances from it. For it is well known, that the nearer either of them is to the burden, the greater share he bears of it; and if he goes directly under it, he bears the whole. So if one man is at A, and the other at a, having the pole or stick resting on their shoulders; if the burden or weight B is placed five times as near the man at A, as it is to the man a, the former will bear five times as much weight as the latter.

This is likewise applicable to the case of two horses of unequal strength to be so yoked, that each horse may draw a port proportionable to his strength; which is done by so dividing the beam they pull, that the point of traction may be as much nearer to the stronger horse than to the weaker, as the strength of the former exceeds that of the latter.

To this kind of lever may be reduced ears, rudders of ships, doors turning upon hinges, cutting-knives which are fixed at the point, &c.

If in this lever we suppose the power and weight to change places, so that the power may be between the weight and the prop, it will become a lever of the third kind; in which, that there may be a balance between the power and the weight, the intensity of the power must exceed the intensity of the weight just as much as the distance of the weight from the prop exceeds the distance of the weight. Thus, let E (fig. 4) be the prop of the lever EF, and W a weight of one pound, placed three times as far from the prop as the power P acts at F, by the cord going over the fixed pulley D; in this case the power must be equal to three pounds, in order to support the weight of one pound.

To this sort of lever are generally referred the bones of a man's arm; for when he lifts a weight by the hand, the muscle that exerts its force to raise that weight is fixed to the bone above, and the part in which the weight is borne is at the end of the arm, and the centre of the bone is the middle. And the arm being the centre round which the lower part of the arm turns, the muscle must therefore exert a force ten times as great as the weight that is raised.

As this kind of lever is a disadvantage to the moving power, it is used as little as possible; but in some cases it cannot be avoided, such as that of a ladder, which being fixed at one end, is by the strength of a man's arms raised against a wall.

What is called the hammer-lever differs in nothing but its form, from a lever of the first kind. Its name is derived from its use, that of drawing a nail out of wood by a hammer.

Suppose the shaft of a hammer to be five times as long as the iron part which draws the nail, the lower part resting on the board as a fulcrum; then by pulling backwards the end of the shaft, a man will draw a nail with one-fifth part of the power that he must use to pull it out with a pair of pincers, in which case the nail would move as fast as his hand; but with the hammer the hand moves five times as much as the nail, by the time that the nail is drawn out.

Let AC be a lever, and P represent a power of this sort, bent at C, which is its prop, or centre of motion. P is a power acting upon the longer arm AC, at A, by the means of the cord DA going over the pulley D; and W is a weight or resistance acting upon the end of the shorter arm CB. If the power is to the weight as CB is to CA, they are in equilibrium; thus suppose W to be five pounds, acting at the distance of one foot from the centre of motion C, and P to be one pound, acting at A, five feet from the centre C; the power and weight will just balance each other.

Thus we see, that in every species of lever there will be an equilibrium, when the power is to the weight, as the distance of the weight from the fulcrum is to the distance of the power from the fulcrum.

In making experiments on the mechanical powers, some difficulties arise from the weight of the materials; but as it is impossible to find any that are without weight, we take care that they are perfectly balanced themselves, before the weights and powers are applied. The bar, therefore, used in making experiments, is made of a sort of wood, as thick or thicker than the long arm, as will be sufficient to balance it on the prop.

Hitherto we have supposed that the power and weight acted perpendicularly upon the lever; but it may be supposed, that they act with some oblique force upon it; the power should, therefore, if possible, be always made to act at right angles to the lever.

If several levers are combined together in such a manner, as that a weight being applied to the first lever, may be supported by a power applied to the last, as in fig. 6. (which consists of three levers of the first kind), and is so contrived, that a power applied at the point L of the lever C, may sustain a weight at the point S of the lever A), the power must here be to the weight, in a ratio, or proportion, compounded of the several ratios, those powers that can sustain the weight of each lever being used singly and apart from the rest, have to the weight.

For instance: if the power which can sustain the weight P by the help of the lever A, is to the weight as 1 to 5; and if the power which can sustain the weight B by the lever B, is to the weight as 1 to 4; and if the power which can sustain the weight C, is to the weight as 1 to 3; then the power which will sustain the weight by the help of the three levers joined together, will be to the weight in a proportion consisting of the several proportions multiplied together, of 1 to 3, 1 to 4, and 1 to 5; that is, of 1 to 60.

For since in the lever A, a power equal to one-fifth of the weight P pressing down the lever at L, is sufficient to balance the weight; and since it is the same thing whether that power is applied to the lever A at L, or the lever B at S, or the point S bearing on the point L; a power equal to one-fifth of the weight P, being applied to the point S of the lever B, will support the weight; but one-fourth of the same power being applied to the point S of the lever C, will as effectually depress the point S of the same lever, as if the whole power was applied at S; consequently a power equal to one-fourth of one-fifth, that is, one-twentieth of the weight P, being applied to the point L of the lever B, and pushing up the same, will support the weight; in like manner, it matters not whether that force is applied to the point L of the lever B, or to the point S of the lever C, since, if S be raised, L, which rests on it, must be raised also; but one-fifth of the weight and one-fourth of the weight, or in other words, the one-hundredth part of the weight, being applied to the point L of the lever C, will balance the weight at the point S of the lever A.

The balance, an instrument of very extensive use in comparing the weights of bodies, is a lever of the first kind, whose arms are of equal length. The points from which the weights are suspended being equally distant from the centre of motion, will move with equal velocity; consequently, if equal weights are applied, their moments will be equal, and the balance will remain in equilibrium.

In order to have a balance as perfect as possible, it is necessary to attend to the following circumstances: 1. The beams ought to be exactly equal, both as to weight and length. 2. The points from which the scales are suspended should be in a right line, passing through the centre of gravity of the beam; 3. The weights should act directly against each other, and no part of either will be lost on account of any oblique direction. 3. If the fulcrum, or point upon which the beam turns, is placed in the centre of gravity of the beam, if the fulcrum and the points of suspension are in the same right line, the balance will have no tendency to one position more than another, but will be in every position in the same manner, and therefore, the fulcrum ought always to be placed a little above the centre of gravity. Its vibrations will be quicker, and its horizontal tendency stronger, the lower the centre of gravity, the less the weight of the point of suspension is loaded.

If the centre of gravity of the beam, when level, is immediately below the fulcrum, it will rest not in any position but when level; and if disturbed from that position, and then left at liberty, it will vibrate, and at last come to rest on the level. In a balance, therefore, the fulcrum ought always to be placed a little above the centre of gravity. Its vibrations will be quicker, and its horizontal tendency stronger, the lower the centre of gravity, the less the weight of the point of suspension is loaded.

4. The friction of the beam upon the axis ought to be as little as possible; because, should the friction be great, it will require a considerable force to overcome it; upon which account, though one weight should a little exceed the other, it will not preponderate, the excess not being sufficient to over come the friction, and bear down the beam.

The axis of motion should be surrounded with an edge like a knife, and made very hard; these edges are at first made sharp, and then rounded, with a fine hone, or piece of buff leather, which causes a sufficient bluntness, or rolling edge. On the regular form and excellence
More than the second, as the circumference of the second wheel exceeds that of the first axle.

In order to a balance here, the power must be to the weight, as the product of the circumferences, or diameters of the two axes multiplied together, is to the circumferences, or diameters of the two wheels.

This will become sufficiently clear, if it is considered as a compound lever, which was explained above. Instead of a combination of two wheels, three or four wheels may work in each other, or any number; and by thus increasing the number of wheels, or by proportioning the wheels to the axis, any degree of power may be acquired.

To this sort of engine belong all cranes or engines for raising great weights; and in this case the wheel may have cogs all round it, instead of handles; and a small lathe, or trudge, may be made to work in the cogs, and be turned by a wheel, which will make the power of the man who works it, as much as the number of revolutions of the winch exceeds those of the axle CD, fig. 9, when multiplied by the excess of the length of the winch above the length of the semidiameters of the circle, or by the radius of the semidiameter or half-thickness of the rope K, by which the weight is drawn up. Thus, suppose the diameter of the rope and axle taken together to be 18 inches, and the circumference of the wheel to be 66 inches, so that the weight W will hang at 63 inches perpendicular distance from below the centre of the axle. Now, let us suppose the wheel AB, which is fixed on the axle, to have 50 cogs, and to be turned by a winch 65 inches long, fixed on the axle of a trundle of eight staves, or rounds, working in the cogs of the wheel; here it is plain, that the winch and trundle would make ten revolutions for one of the wheel AB, and its axis CD, on which the rope K winds in raising the weight W; and the winch being no longer than the sum of the semidiameters of the great axle and rope, the trundle could have no power more than this length; and the man could have by pulling it round by the edge, because the winch would have no greater velocity than the edge of the wheel has, which we have here supposed in ten times as great as the velocity of the rising weight. In this case, the power gained would be as 10 to 1. But if the length of the winch is 13 inches, the power gained will be as 20 to 1; if 19 inches (which is long enough for any man to work by), the power gained will be as 30 to 1; that is, a man could raise 30 times as much by such an engine, as he could do by his natural strength without it, because the velocity of the handle of the winch would be 30 times as great as the velocity of the rising weight; the absolute force of any engine being in the proportion of the velocity of the power, to the velocity of the weight raised by it.

In this sort of machines it is requisite to have a ratchet wheel on the end of the axle C, with a catch to fall into teeth which will at any time support the weight, and keep it from descending, if the person who turns the handle should, through inadvertence or carelessness, quit his hold while the weight
These rules hold good, whatever may be the number of pulleys in the blocks. If, instead of rounding all the pulleys, the rope belonging to each pulley is made fast at top, as in fig. 17, a different proportion between the power and the weight will take place. Here it is attended that each pulley doubles the power: thus, if there are two pulleys, the power will sustain four times the weight.

Fig. 8, is the concentric pulley, invented by Mr. James White. O, R, are two brass blocks, in which grooves are cut; and round these a cord is passed, by which means they answer the purpose of so many distinct pulleys. The advantage gained is found by doubling the number of grooves in the lower block.

It is common to place all the pulleys in each block on the same pin, by the side of each other, as in fig. 18; but the advantage, and rule for the power, are the same here as in fig. 6.

A pair of blocks with the rope fastened round it, is commonly called a tackle.

The inclined plane. This mechanical power is of very great use in rolling up heavy bodies, as casks, wheelbarrows, &c. It is formed by placing boards, or earth, in a sloping direction.

The force wherewith a body descends upon an inclined plane, is to the force of its absolute weight, as the sine of the given angle of the plane, to the perpendicular, or height of the plane, to its length. For suppose the plane AB (fig. 19) to be parallel to the horizon, the cylinder C will keep at rest on any part of the plane AB it is laid on. If the plane is placed perpendicularly, as AB, fig. 20, the cylinder C will descend with its whole force of gravity, because the plane contributes nothing to its support or hindrance; and therefore it would require a power equal to its whole weight to keep it from descending.

Let AB (fig. 21) be a plane parallel to the horizon, and AD a plane inclined to it; and suppose that the length AD to be ten times as great as the perpendicular DB. In this case, the cylinder E will be supported upon the plane DA, and kept from rolling, by a power equal to a third part of the weight of the cylinder, if therefore a wedge may be rolled up this inclined plane, by a third part of the weight of the wedge, which would suffice to draw it up by the side of an upright wall.

It must also be evident, that the less the angle of elevation, or the gentler the ascent is, the greater will be the weight which a given power can draw up; for the steeper the inclined plane is, the less does it support of the weight; and the greater the tendency which the weight has to roll, consequently the more difficult for the power to support it: the advantage gained by this mechanical power, therefore, is as great as its length exceeds its perpendicular height.

To the inclined plane may be reduced all hatches, chisels, and other edge-tools.

The wedge is the fifth mechanical power or machine: it may be considered as two equally inclined planes, joined together at their bases; then DG (fig. 22) is the whole thickness of the wedge at its back ABG, where the power is applied; EF is the depth or height of the wedge; BF the length of one of its sides; and OF is its sharp edge, which is entered into the wood intended to be split, by the force of a hammer or mallet striking perpendicularly on its back. Thus, A B (fig. 23) is a wedge driven into the clerk C D of the wood FG.

When the wood does not cleave at any distance from the wedge, there will be an equilibrium between the power impelling the wedge downward, and the resistance of the wood acting against the two sides of the wedge, when the power is to the resistance as half the thickness of the wedge at its back is to the length of either of its sides; because the resistance then acts perpendicular to the sides of the wedge. But when the resistance on each side acts parallel to the back, the power that balances the resistances on both sides will be, as the length of the whole back of the wedge is to double its perpendicular height.

When the wood cleaves at any distance before the wedge (as it generally does), the power impelling the wedge will not be to the resistance of the wood as the length on the back of the wedge is to the length of both its sides, but as half the length of the back is to the length of either of its sides, estimated from the top or acting part of the wedge. For, if we suppose the wedge to be lengthened down from the top CE, to the bottom of the clerk at D, the same proportion will hold, namely, that to double the resistance as half the length of the back of the wedge is to the length of either of its sides: or, which amounts to the same thing, as the whole length of the back is to the length of both its sides.

The wedge is a very great mechanical power, since not only wood, but even rocks, can be split by it; which it would be impossible to effect by the lever, wheel and axle, or pulley; for the force of the blow, or stroke, shakes the cohering parts, and thereby makes them separate more easily.

The screw (fig. 24) is the sixth and last mechanical power, but cannot properly be called a lever. By a screw a current of water never used without the application of a lever or wedge to assist in turning it; and then it becomes a compound engine of a very great force, either in pressing the parts of bodies closer together, or in lifting heavy weights. It may be conceived to be formed by a piece of paper, ABC (fig. 25), into the form of an inclined plane, or half-wedge; and then wrapping it round a cylinder (fig. 26), the edge of the paper AC will form a spiral line round the cylinder, which will give the thread of the screw. It being evident that the winch must turn the cylinder once round, before the weight of resistance can be moved from another; therefore, as much as the circumference of a circle described by the handle of the winch is greater than the interval or distance between the spirals, so much is the force of the screw. Thus, supposing the thickness of the spirals to be half an inch, and the length of the screw twelve inches, the circle described by the handle of the winch where the power acts will be 76 inches nearly, or about 159 half-turns, which nearly 122 times as great as the distance between the spirals; and therefore a power at the handle, whose intensity is equal to no more than a single pound, will balance 152 pounds acting against the screw; and as much additional force as...
MECHANICS.

127

is sufficient to overcome the friction, will raise the 152 pounds; and the velocity of the power will be the velocity of the weight, as 152 to 1.

Hence it appears, that the longer the winch is, and the nearer the spirals are to one another, so much the greater is the force of the screw.

A machine for shewing the force or power of the screw may be contrived in the following manner:—Let the wheel C have a screw (fig. 24) on its axis, working in the teeth of the wheel D, which suppose to be 48 in number.

It is plain, that for every time the wheel D is turned, and screwed by the winch A, the wheel D will be moved one tooth by the screw; and therefore, in 48 revolutions of the winch, the wheel D will be turned once round.

Then, if the circumference of a circle, described by the handle of the winch A, is equal to the circumference of a groove round the wheel D, the velocity of the handle will be 48 times as great as the velocity of any given point in the groove. Consequent ly, i.e., a line so many pounds hung to the wheel, has a weight of 48 pounds hung to it, a power equal to 1 pound at the handle will balance and support the weight. To prove this by experiment, let the circumferences of the groove of 48, and the cylinder of 48, be equal to one another; and then if a weight H, of 1 pound, is suspended by a line going round the groove of the wheel C, it will balance a weight of 48 pounds hanging by the line G; and a small addition to the weight H will cause it to descend, and so raise up the other weight.

If a line G, instead of going round the groove of the wheel D, goes round its axe I, the power of the machine will be as much increased as the circumference of the groove exceeds the circumference of the axe; which suppose to be six times, then one pound at H will balance six times 48, or 288 pounds, hung to the line on the axe; and hence the power or advantage of this machine will be as 288 to 1. That is, a man who by his natural strength could lift a hundredweight, will be able to raise 285 cwts. by this engine. If a system of pulleys was applied to the cord HI, the power would be increased to an amazing degree.

When a screw acts in a wheel in this manner, it is called an endless screw.

When it is not employed in turning a wheel, it consists of two parts: the first is called the male or outside screw; being cut in such a manner, as to have a prominent part going round the cylinder in a spiral manner, which prominent part is called the thread of the screw; the other part, which is called the female, or inside screw, is a solid body, cut transversely, whose concave surface is cut in the same manner as the convex surface of the male screw, so that the prominent parts of the one may fit the concave parts of the other.

A very considerable degree of friction always acts against the power in a screw; but this is fully compensated by other advantages; for on this account the screw continues to sustain a weight, even after the power is removed, or ceases to set, and presses upon the body against which it is driven. Hence the screw will sustain very great weights; insomuch that several screws properly applied, would support a large build,

ing, whilst the foundation was mending, or renewed.

OF COMPOUND MACHINES.

Though it is evident from the principles delivered above, that any one of the mechanical powers is capable of overcoming the greatest possible resistance, in theory; yet, in practice, if used singly for producing very great effects, they would be frequently so unwieldy and unmanageable, as to render it impossible to apply them. For this reason, it is generally found more advantageous to combine them together; by means which the power is more easily applied, and many other advantages are obtained. In all machines, simple as well as compound, what is gained in power is lost in time. Suppose that a man, by a fixed pulley, raises a beam to the top of a house in two minutes, it is clear that he will be able to raise six beams in twelve minutes; but by means of a tackle, with three lower pulleys, he will raise the six beams at once, with the same ease as he before raised one; but then he will be six times as long about it, that is, twelve minutes; thus the work is performed in the same time, whether the mechanical power is greater or not. But the convenience gained by the power is very great; for if the six beams are joined in one, they may be raised by the tackle, though it would be impossible to move them by the unassisted strength of one.

Consequently, if by any power you are able to raise a pound with a given velocity, it will be impossible, by the help of any machine, to raise two pounds with the same velocity. But, by the help of a machine, you may raise two pounds with half that velocity, or even one thousand with the thousandth part of that velocity; but still there is no greater quantity of motion produced, when a thousand pounds are moved, than when one pound is moved; the thousand pounds moving proportionally slower.

No real gain of force is, therefore, obtained by mechanical contrivances; on the contrary, from friction, and other causes, the working parts are always lost; the machines we are able to give a more convenient direction to the moving power, and to apply its action at some distance from the body to be moved, which is a circumstance of infinite importance. By machines also, we can modify the energy of the moving power, as to obtain effects which it could not produce without this modification.

In machines composed of several of the mechanical powers, the power will be to the weight, when they are in equilibrio, in a proportion formed by the multiplication of the several proportions which the power bears to the weight in every separate mechanical power of which the machine consists.

Suppose a machine, for instance, composed of the axle in the wheel, and a pulley; let the axe and wheel be such, that a power consisting of one-sixth of the weight will balance it; and let the pulleys be such, that by placing the power equal to one-fourth of the weight, we would support it: then, by means of the axe in the wheel, and the pulleys combined, a power equal to one-fourth of one-sixth, that is, ⅙ of the weight, will be in equilibrio with it.

In contrivings machines, simplicity ought particularly to be attended to; for a complicated machine is not only more expensive, and more apt to be out of order, but there is also a greater degree of friction, in proportion to the number of rubbing parts.

Whatever may be the construction of a machine, its power will proceed directly as the proportion of the velocity of the power to the weight; and so that this is obtained in the greatest degree that circumstances will admit, or that are necessary, then the fewer parts the better.

It is evident from the principles already laid down, that the velocity of a machine is equal to that of a pinion, or smaller wheel which is driven by it, in proportion to the diameter, circumference, or number of teeth in the pinion to that of the wheel. Thus, if the number of teeth in a wheel are 60, and those of the pinion 5, then the pinion will go 12 times round for once of the wheel, because 60, divided by 5, gives 12 for a quotient.

Hence, if you have any number of wheel's teeth, and wish to divide the product of the teeth in the wheels by those in the pinions, and the quotient will give you the number of turns of the last pinion in one turn of the first wheel. Thus, if a wheel (fig. 27) of 48, acts upon a pinion B of 8, on whose axis there is a wheel C of 40, driving a pinion D of 6, carrying a wheel E of 36, which moves a pinion F of 6, carrying an index; then the number of turns made by the wheel A will be equal to: 8X4X3=96, 96=240, the number of turns which the index will make while the wheel A goes once round.

Any number of teeth on the wheels and pinions having the same ratio, will give the same number of revolutions to an axis; thus, 8X4X3=96, 96=240, as before. It therefore depends upon the skill of the engineer, or mechanic, to determine what numbers will best suit his design.

It is evident, that the same motion may be performed, either by one, or by a number of machines, or by many wheels and pinions, provided the number of turns of all the wheels bear the same proportion to all the pinions which that one wheel bears to its pinion.

When a wheel is moved immediately by the power, it is called a leader, and B becomes a follower. If there is another wheel on the same axis, it is called the follower. Thus A, being moved immediately by the power, is to be considered as a leader, and B as a follower; the wheel C being driven by B, becomes a leader, and D a follower; E (fig. 28) is a leader, and the cylinder F may be considered as a follower.

Sometimes the same wheel acts both as a leader and a follower; as in fig. 29, where B is moved by A, and consequently is a follower; while, as the cylinder D is led by B, it is also a leader. Therefore, as to multiply both the divisors and dividend by the same number does not alter the quotient; in mechanical calculations, every wheel that is both a leader or a follower may be treated of as a single leader. The power of a machine is not at all altered by the size of the wheels, provided the proportions to each other are the same.

On the application of men and horses, as moving powers in machinery, &c. A horse draws with the greatest advantage, when the line of draught is not level with his breast, but
MEDAL. denotes a piece of metal in the form of coin, such as was either current mon-
ey among the ancients, or struck on any particular occasion to preserve the portrait of some great person, or the memory of some illustrious action, to posterity. Its etymology is not explained, but is of little consequence, though the best authorities give it from a "met-
tallum."

To enlarge on the utility of medals in the sciences, were needless. As historical doc-
uments, they form the principal evidence we can have of the life of our ancestors. In some few instances they correct the names of sovereigns; and in a great many, illus-
trate the chronology of reigns. By their as-
sistance the geographer has sometimes been enabled to determine the situation of a town whose name alone has reached us. To the naturalist they afford the only proofs of the knowledge which the ancients had of certain plants and animals; and they sometimes pre-
serve details of historical buildings for the tect, of which not even a ruin is, at this day, standing. The connection of medals and poetry has been treated at considerable length by Mr. Addison. To the connoisseur they are not entirely necessary, as they enable him to appreciate the busts and portraits of antiquity. And the scholar need hardly be reminded that they have contributed in so small degree to the elucidation of obscure passages in the classics. The altering of the Greek coins is one of the best schools of study for the sculptor.

The study of medals, perhaps, is not of very ancient date. The preservation of the Greek coins among their choicest treasure, is said to have been one of those marks of due respect which the Romans showed the Greeks: but the knowledge of medals in se-
ries does not seem to have formed a distinct branch, either of study or entertainment, till the revival of literature in Europe. Petrarch is related to have been one of the first who began to study the medallie science. Al-
phonso, king of Aragon, formed another col-
lection.

And a third was placed by Cosmo de Medici in Florence, of the curiosities in the Museum at Florence.

In this country, though we know of the ex-
istence of no cabinet before the time of Cam-
den, it may be fair to suppose that the know-
ledge of Greek and medals was introduced from Italy. The "Britannia" was the first work in which engravings of them were pro-
duced: and Speed's Chronicle, which soon followed it, was illustrated with coins from the collection of Sir Robert Cotton. Henry prince of Wales was one of the first who had a rich cabinet; and he bequeathed it at his de-
th to Charles. The most considerable of our other early collectors were, archbishop Land, lord Arrolld, Mr. Selden, Oliver Cromwell, we are told, had small collec-
tion; and the cabinet of Charles the Second is mentioned by Vaillant.

In the article here presented to the reader's notice, we shall give first a brief account of the coins of the most antient nations which are still extant; reserving the Greek and Roman, which are the most interesting of all coins, for a more extended view; add-
ing, at the close, a particular though con-
densed history of the coins and coinage of England. For the first part, as well as for

what lower degree.
MEDALS.

part of an ounce, of which Mr. Pinkerton describes the nominal value to be 4
sterling: the diadrachm, tradrachm, and tetradrachm, explain themselves, except the
tetradrachm of the Augustan standard, which was valued at five shillings. This last was
the largest form of the Greek silver coin. The silver divisions of the drachma were the
tetroboion, the hemidrachma or trithron, the diobolion, the obolus, the hemiobolion, the
tetrobolion, and diachalkos; the first of the va-
tue of sixpence, and half a crown. Of the distinct names by which many of
these coins were called among the different states, our intelligence is partial; nor are
such names of consequence.

The next Greek coinage, in point of antiquity, is that of copper, which is said not to
have been introduced till four hundred and four years before the Christian era. The
first copper coin of Greece was the chalcus, of which two went to the quarter of the silver
ounce. In days of prosperity, however, even this was divided by different states into dif-
dent portions, which were called aetta, or little coins. The lepton, dilepton, and
trochyleon, were the divisions of the chalcus, the smallest of which, the diachalkos, the
size, are very rare. Such were the brass coins of Greece previous to the subjacent
of that country to the Roman empire.

The earliest of the gold coins of Greece are those of Philip of Macedon, although they
were struck in Sicily considerably earlier. Philip, having conquered the city Crenides,
on the confines of Thrace, found gold-mines in its neighbourhood, formerly ill explored,
and of small produce. From this gold he first struck the coins called Philippus, because of
his portrait which appears on them. The Philippus it should seem were diadrachms, the
form most universal in the ancient coinages of gold; and at their first appearance went for
20 silver drachmas, but in latter times for 2: Greek drachma or Roman denarius. The
Philippus was also called ἄσπες. There were likewise the τριπλάσιον and the τετραπλά
σιον, with gold double the weight, which could not have gone for more than double the
silver. There were also the 2 θεσσαλικά and the Τριτεραχάς, or quadruple ἄσπες; the for-
mer worth about two, and the latter worth about four mullets of our money.

The original value of the Roman coin is a subject still more intricate and extensive. As
in Greece, the first estimation of their money was by weight: though copper, not silver,
was the first medium of coinage. The first Roman coinage, according to Mr. Pinkerton,
was in the reign of Tiberius and Caracalla, about the year 430 before the common era, and
was to the as or 2s libra, or piece of brass only, which was stamped with the two-
headed image of Janus on one side, and the prow of a ship on the other; though Mr. Pinsky
afterward thinks, it probable that the very first Roman ases of Tullus had the figure of a bull, ram, or other species of cat-
tle. However this may be, parts of the as were very early given in proportion of weight
and value: such were the semi or half, the	trios, the quadans, the sextans, and the uncia.
After a certain period, the as, though still called the ases ouo or piece of brass, fell in weight; larger denominations were
coined. Such were the bissus or dupondius,
emperors’ heads in their several medals. The

crown of laurel is continually seen; and

Agrippa appears not only, with the crown, but the mural crown. The successors of Alexander assumed, by way of distinction, different symbols of deity on the busts of their medals. A few instances also occur, among the Roman coins, of the helmet.

The reverses of medals, both among the Greeks and Romans, were of infinite variety. They contain figures of deities at whole length with their attributes and symbols; public buildings and divers ions; allegorical representations, historical and private events; figures of ancient statues; subjects of natural history; magistracies, &c.

The reverses of the Roman coins have more of art and design than the Greek, though the latter have more exquisite relief. It is very evident that no reverse is found, and of the ancient Greek reverses some are in

The figures of deities and personifications on the Roman coins, are commonly attended with the names: the figure of Virtue with VIRTVS AVGVS; but on the reverse of the Greek coins the figure is only accompanied by some certain symbol; as in Athens, wheaten garland, Man with his arm or, Mercury with his caduceus. The anchor on Seleucian coins is the mark of Antioch; the owl, of Athens; the labyrinth, of Crete; the horse, of Thessaly; and so on.

Of the legends, the early Greek coins usually contain the name or the initials of the city they belong to; or the name, the first character of it, or the monogram, of the prince. The earliest coins of Athens have only ΑΘ, money of Athens: ΣΤ, of Syrakusis; ΜΑΣ, of Massilia. ΣΥΑΛΟΚΟΣΙΝ occurs at full length, as well as ΦΙΛΙΑΠΟΣ for Philip of Macedon. And though in aftertimes the names of princes were accompanied by modest adjacents, there were others that were not a little proud. Of the former were ΔΙΚΑΙΟΥ, ΕΥΣΕΒΟΥΣ ΦΙΛΑΞΗΝ of the latter, ΘΕΟΛΑΡΟΤΟΣ, ΒΑΣΙΛΕΩΣ ΒΑΣΙΛΙΑΝ, &c.

After the Roman empire had swallowed up the Greek, the legends on Greek coins became as remarkable for length as they had before been for brevity. The Greek imperial coins have a great variety in their legends, which explains the variety of the reverses ranging in adulteration. The legends of the Roman imperial coins are still more deservedly celebrated for their beautiful simplicity. ΙΝΔΕΑ ΚΑΠΤΑ and ΑΣΙΑ ΣΟΒΑΣΚΑ are sufficient instances.

Of the pieces produced by the ancient mints, there were some of a size which seemed evidently to have been intended for something else than circulation. Medallions were occasionally presented by the emperor to his ministers; and sometimes by the imitator to the emperor as specimens of workmanship. These are usually known by their weight, which is far greater than that of the acknowledged money. Both the Greek and Roman medallions appear to have been principally struck in the imperial periods. Till the time of Hadrian they are rare. For a more full account of them, we refer to the work of Mr. Pinkerton.

To dwell longer on the various types and titles of the Greek or the Roman coins, would be superfluous. Their curiosity and elegance are infinite. The regal coins of Greece are interlaced from their portraits; the coins of cities, from their importance to geography. On the consular coins of Rome, the names and titles of the consuls do not appear till toward the close of the series; the brass consular coins are uninteresting. The imperial brass is of three sizes, large, middle, and small; the first forming a series of the greatest beauty. The imperial silver coins are numerous; the gold, of wonderful perforation. Often a half obverse having occurred both upon the Greek and Roman coins, we shall refer to the Tables selected by Mr. Pinkerton, as it would be impossible, in so concise a work as this, to give every information which the collector might require. The best works upon the Greek and Roman coins are probably these: Froelich’s Notitia Eccentricae; Numa’s Poema, &c. We refer the student to that work for the means of learning the names of the emperors, and their titles.

Those of Stephen which have the banner, are the rarest. The pennies of Henry the Second are also scarce; of Richard the First we have only the French penny; and of John only a copper mark. Of Edward the Third, though of the last there are not only pennies but halfpennies and farthings. The first coinage of Henry the Third had only on the obverse BERNICVS REX; and his penny was large and weighed no longer personally ascribed to Henry the Second. After his 39th year, we find III or TERCII added to the title. The pennies, halfpennies, and farthings of Edward, the First are all common. Salford pennies have EDW. RANGL. DNS.HIBY upon the obverse, are usually ascribed to Edward the First; those with EDWA. or EDWAR. to Edward the Second; and those with EDWARD or EDWARDVS to Edward the Third. This, however, is but conjecture. In the 18th of Edward the Third, the penny was brought down to 20 grains; and in his 27th year, we had halfpence and halfpence, in which the king’s head was surrounded by a sort of a double treble. In the reign of Edward the Fourth, having previously sunk to 13, the penny fell to 12 grains. In Edward the Fifth’s time, it was reduced to 6, and in Elizabeth’s to little more than seven. Of the groats, Richard the Third is very rare. In 1503, Henry the Seventh coined the shilling or testoon: it resembled the groat, but had no more value than 145 or 150 farthings. The crown of silver was first struck by Henry VIII. and the half-crown, sixpence, and threepence, by Edward the Sixth. Elizabeth, in 1558, coined three halfpence, and in 1568, three forthing pieces; but they were disused in 1582. Henry the Eighth was the first of our princes who debased the coinage; and in the earlier part of Edward the Sixth’s reign, the practice was continued. But from the 4th of Elizabeth, 1601, the denomination, weight and fineness of English silver, have remained the same. From 1601 to 1628, the money of Elizabeth was of a new taste. By a mill and screw; but the artist of this money being hanged for counterfeiting coins, the hammering system was again recurred to. Till the time of Charles the Second, we have little more of the milled money.

The design of a gold coinage appears to have been first formed by Henry the Third, the most particular account of which is to be found in Lord Liverpool’s Letter to the King. The piece ordered to be current was called a gold penny; but being of too great value for general circulation, it was in two or three years called in, and now but three specimens of gold halfpence and halfpence, to be a beautiful specimen of the coinage of the time. The obverse is much in the manner of the king’s great seal, and the inscription HENRICI REX III.; on the reverse, the mint-master’s name and place. The three known are all of different types: one reads LVND, another LVNDE, and the third LVNDEN. But it is from Edward the Third that the series of our gold coins commences. In 1244, he struck the florin, half, and quarter florin. The florin was current for six shillings, but
MED
MED
was the same year succeeded by the noble,
the value of which was half a mark. Henry
the Fifth diminished the value of the noble;
and Henry the Sixth restored it to its size, and
gave it the name of ryal; while Edward the
Fourth, in 1465, supplanted it with the angel.
Henry the Eighth, in 1523, added the gold
crown and the sovereign to their present
value: the sovereign of 22s. 6d.; the crown
at 2s. 6d.; and the noble at its old value.
In 1546, he coined sovereigns and
half-sovereigns, the former to go at 20s.
and the latter in Occre, Charles the Second,
however, instead of the sovereign and
the guinea and half-guinea. George the First
added the quarter-guinea. But though it was
continual in the early part of the reign of
his present majesty the seven-shilling piece
has been preferred.

The history of our copper coinage, the
last in order of chronology, will be shorter.
From the reign of Henry the Eighth till the
close of his reign, the scarcity of silver
halfpence and halfpence, up to the
introduction of tokens or pledges for
money among tradesmen, many of which are
thereafter employed to what in what has been said
by Erasmus, and other learned
men. Elizabeth, it appears, would neither
hears of a copper coinage for the country;
and though farthing tokens of copper were
issued both under James and Charles the First,
they were considered rather as pledges of
a government than legitimate money. The
death of Charles the First put an effectual
stop to their further currency; and till 1672.
the farthing was employed with town pieces
and tradesmen's pledges; seven, in the
latter year, halfpence and farthings of copper
were made public money, and the circulation of
tokens forbidden. His present majesty has
added two-shilling pieces.

MEDEOLA, Clingking African aegraphe, a genus of the hexandria order, in the
trigynia class of plants, and in the natural method
ranging under the 11th order, sarcc-
mentacea, a family of the corolla is sepertite and revoluted; the
seeds are spurious. Its characters are these: the flower
has no emplente; it has six oblong oval
petals, and six and-bladed zamina terminated
by a single pistil, and a straight
germina terminating the style; the
germina afterward turn to a roundish trided berry with
two cells, each containing one heart-shaped
seed. There are three species.

MEDICAGO, small-trained, a genus of
the decandria order, in the diacleral class of
plants, and in the natural method
ranging under the 22d order, papilionacea. The
leaves is compressed and screwed; the cali-
bris of the corolla is doved in the vex-
illum. There are 12 species, though only
five are commonly cultivated in this country.
They are low trifling plants, adorned with
small yellow flowers, succeeded by small
round snail-shaped fruit, which are downy,
and armed with a few sharp spines. They
are easy propagated by seeds. The M.
sempervirens, has been latterly much
reputed as a green fodder for cattle, and
has been cultivated by some farmers with
success.

MEDICINE, is the art of preserving
health, and of curing or alleviating disease.
It is the same science in its application to
animal, as agriculture to vegetable, life.

Origin and progress of medicine. "Med-
cinae usque ad non est." This art arises
out of the natural, as others more gradually
and indirectly originate from the artificial and
adventitious, wants of mankind. The exact
period, however, in which medicine began
to be formally practised as an art, or sepa-
rately cultivated as a profession, has by no
means been accurately ascertained. All the
accounts which have been transmitted on
this subject from a date prior to the time of Hip-
ocrates, are either conjectural or fabulous.
Hippocrates first effected a separation of
medicine from philosophy and science, and
gave it the form of a distinct science: he has there-
fore been generally regarded by the moderns
as the father of physic; and from his time
the history of this science may be made with

Hippocrates was a native of Greece. He
was born in the island of Cos, and flourished
about 400 years prior to the christian era.
He was, in his character as a physician, an
estimate cure, professedly with the accuracy,
be formed from his writings, or from those works
which have been attributed to him, but which
are generally regarded as in a great measure
the inventions of his disciples and successors.
"Hippocrates," says an authority,
"lived at too early a period to be acquainted
with the collateral branches of science. He
studied life and disease in the book of nature,
and had the merit of an original observer."
We do not, however, appear to have
this author fully to acquit the "Coan sage
of the many idle theories which have been
imputed to him." It may well be conceived that
he was influenced in his opinions on the
disease of the cause and the nature of disease,
particularly, if not by the splendid ficitions of the Greek
philosophy, by preconceived theory and vague
conjecture. Indeed, the hypotheses contain-
ed in the reputed writings at least of Hippo-
ocrates, have been, with trivial modifications,
the hypotheses of modern times; for in this
author's perceiving and pressing principle
of nature, and in his attraction, depuration,
decosition, and crisis of disease, he may be traced
the same mode of theorizing which has been
adopted by later systematics.

The humoral pathology, and even the vis
natural medicatrix of modern times, appear
to be modifications or relics of Hippocratic
reasoning.

The immediate successors of Hippocrates
began to direct their researches into the aux-
iliary departments of medicine; and among
these, Praxagoras, Chrysippus, Hephatus,
and Erastius, particularly the two last,
made no inconsiderable discoveries (when we
consider the scantiness of their materials)
respecting the structure and functions of the
human frame. It was during his period, ac-
cording to Celsus, that the science was di-
vided into the three distinct branches of
dietetic, pharmacological, and chimerical
medicine—vis manu operata, vis medicamentosi,
tertia quae manu medicatur. Shortly
after the time of Herophilus, the medical
work became divided into the two sects of
empirics and dogmatists; the one, rejecting
the reasoning and deriding the practice of
their predecessors, affected to divest all
authority but that of experience; the other,
retaining their faith in the scholastic philoso-
phy of the times, and their conviction of the
utility of physiological knowledge in detect-

ing the causes and regulating the treatment of
disease. The empiric sect was founded by
Sparacio of Alexandria, about 257 years be-
fore Christ.

The next revolution in importance in
the medical art was occasioned by the introduc-
tion of the Epicurean philosophy into the
schools of medicine. This was effected by
Asclepiades, who was succeeded by Themi-
sion, the founder of the medical sect, the
members of which were equally hostile to the
dogmatists and empirics. They discarded
what they considered the occult reasoning of
the former, and substituted in the room of the
laborious observations of the latter, indica-
tions of treatments deduced from the analogy
of diseases, or the mutual resemblance they
bear to each other, "nullus causae nostrum
quisquam ad curatum pertineat; satius
case quidem commuee morborum medici
temethodici contundit," Celsus. The most
celebrated of Themison's followers were
Thelephilus, who flourished under the em-
peror Nero, and Soranus, a native of Ephesus,
who lived during the time of the emperors
Trajan and Adrian.

We have now arrived at a very conspicu-
ous era in the science of medicine. About
the 13th year after Christ, in the reign of
Adrian, lived the celebrated Galen, who was
more than 150 years before our period.
Galen undertook the reformation of medi-
cine, and affected to reconcile the Epicurean
philosophy and practice. Instead, however,
of abiding by the doctrines of his master, his
system was almost entirely of his own in-
vention. "Both philosophy and science had
made some advances; and from those sources
Galen introduced many corruptions into
medicine." Like Hippocrates, he supposed
the existence of four humours, from the pre-
dominancy or deficiency of one or other of
which the varieties of constitutional
theisoic,

The complexity and nature of disease
were conjured to originate. These
humours are, in the Galenic system, the blood,
the phlegm, the yellow bile, and the black
bile. He likewise attached different
kinds of spirits—the natural, the vital, and
the animal; the first of which he supposed to
be a subtle vapour arising from the blood;
the last, to the heart, becomes, when
conjoined to the air taken into the lungs,
the vital spirits, which are changed into the
animal kind in the brain. These three species
of spirits our author imagined to serve as
substrates to distinct faculties: the
natural faculty, which he supposed to reside
in the liver, and to preside over the nutrition,
growth, and generation of the animal body;
the vital faculty, which he lodged in the
heart, yellow bile, and the black bile.
He likewise attached different
kinds of organs—arteries, veins, nerves, and
the like. The special functions of each
organ or principle of motion in these respective
faculties, Galen, as well as Hippocrates, calls
nature.

The authority of Galen, notwithstanding
the tissue of extravagances and idle conject-
ratures of which his systems were founded,
con-
MEDICINE.

In this work it is asserted, or rather perhaps conjectured, that a known channel, passes from the pulmonary arteries into the veins. Even allowing that this intimation justly laid claim to the title of a discovery, it is merely a discovery of the passage of the blood through the lungs, could in no measure interfere with the merit or be regarded as an anticipation of the Harveyan doctrine.

The period, however, had not yet arrived when a rational system to be made of medical facts and important in question. As the alchemists had derided the Galenists, so the reasons of the latter were now to give way to the mathematical art of physicians, who by axioms, postulata, theorems, problems, experiments, and corollaries, ("a capite alcali armatss, et necem unidine ministrant," attempted to explain, in the most futile manner, the functions of life, and to regulate the remedial practice.

The learned and industrious Boerhaave, of Leyden, whose name stands conspicuous in the annals of medicine, at length attempted to restore the authority of the ancient writings; and by uniting the doctrines of Hippocrates with those of Paracelsus, he framed a theory of medicine upon the supposition of acrimony, leucor, and other changes in the circulating fluids. From these changes he inferred the origin of all disease; and the process of cure is, according to Boerhaave, either the process of correcting or expelling acrimony from the body, or the correction of morbid viscidity or tenuity in the humourists. Boerhaave has, therefore, been considered the founder of the humoral pathology; a pathology which even to this day retains a material influence on the opinions, the phrenologism, and the practice at least of the vulgar.

Contemporary with Boerhaave was the illustrious Hoffmann, a German professor, and founder of a medical system. Dr. Stahl havig first suggested, or rather borrowed from the ancients, the idea of the rational soul of man governing the economy of his body, and divating the adverse tendency of noxious agents by exciting such actions in the system as are calculated to effect their expulsion, or destroy their malignity; Stahl endeavoured to state, that the first operation of the cause creating disease was the production of universal aloy or spasm in the primary moving powers of the system, and did not consist of changes produced either in the quantity or quality of the humours or fluids of the body, as taught by the celebrated Boerhaave.

The humoral, however, continued to prevail over the pathology of Hoffmann; and Dr. Cullen informs us, that "when he came to take a professorship in the university of Edinburgh, he found the Boerhavian system then in its full force." In framing a system of his own, Dr. Cullen reverted to the theory of Hoffmann; and indeed the whole of his pathology, in fact, relates to two leading diatomic doctrines, is scarcely anything more than an attempt to unite the hypothesis of Hoffmann with the Stahlian principle of an intelligent, preserving, and preservative power.

We have thus rapidly conducted our readers over the ground of medical history, and have presented a faint outline of the prevailing systems of medical philosophy, from the time of the Grecian to the time of the "Future Hippocrates," to the period when the fanaticism and prejudice of system were shortly to give way before the precepts of genuine philosophy and temperate induction; when new eras should be established upon a new foundation; when chemistry was to undergo a reform, equally rational and important; when by consequence a new alliance was to be formed between these two sciences, the language of metaphor and hypothesis was to be discarded from either; and when enquirers after truth were to be influenced and directed by the independent and invaluable axiom, "Nil prius regeri, nisi primum intelligi."
which Brown aimed at. His division is a guide to the student, but not to his physician. A recent attempt has been made to include in one scheme both general principles and particular facts. This plan, however, notwithstanding the boldness of conception by which it was conceived, and the brilliancy by which it has been executed, is defective. It rests upon a hypothetical, and therefore upon a sandy, foundation. Our readers who are acquainted at all with modern medicine, will be at no loss to conclude that we refer to that system of the late Dr. Darwin. By this author, excitability, which was left as an ultimate fact in the Brutonian theory, is attempted to be traced to its origin. The sensorial power, excitability, or spirit of animation, is conceived to be "a subtle fluid, residing in the brain and nerves, and liable to general or partial accumulation." The vital changes effected by the medium of this imaginary fluid, are, 1st, "Irritation, which is an excitement or change of some extreme part of the sensorium residing in the muscles or organs of sense, in sequence of the appulse of external bodies. 2. Sensation, which is the power to perceive the several parts of the sensorium, or of the whole of it, beginning at some extreme parts of it, which reside in the muscles or organs of sense. 3. Volution is an excitement or change of the central parts of the sensorium, or of the whole of it, terminating in some extreme parts of it, which reside in the muscles or organs of sense. 4th. Association is an excitement or change of some extreme part of the sensorium residing in the muscles or organs of sense, in consequence of some antecedent or attendant fibrous contractions."

With these assumptions as his guide, Dr. Darwin endeavours to penetrate deeper into the cause of disease than is allowed by a mere knowledge of the condition of the fibre. The powers of the sensorium are the proximate cause; the fibrous action, the excitement of Dr. Brown, the proximate effect; and hence, from an incomplete knowledge of the mind, the sensorium, statement of the mode in which excitations are produced, he treats of diseases as occasioned by the comparative redundancy or deficiency of the sensorial power of irritation, and not of the fibrous action. It would carry us far away beyond our limits to pursue this theory through the minutiae of its ramifications. Some opportunities will be afforded in the course of the present article to acknowledge the obligations which medicine is under to its ingenious framers. We shall here confine ourselves to the statement of what we consider fundamental objections to the doctrines, and, by implication, the nosology or arrangement of Zoonomia.

In the first place, it does not distinguish between cause and effect, between the resultant motion and its source. Secondly, it substitutes, like the antient systems, mere statements of phenomena for explication of their origin. Thirdly, and what is more immediately applicable to our present enquiry, it divides that which in nature is indivisible.

Dr. Brown had defined excitement to be a certain state of fibrous action produced by the exciting powers acting upon the excitable substance, and that after him considers irritation or excitement as an exertion of the spirit of animation, exciting the fibres to contraction. Here we observe the want of precision, indulged in, and the conclusion originates from forsaking induction to embrace hypothesis. "On Dr. Darwin's principles the identical fibrous motion exists before the faculty of irritation can be exerted." The spirit of animation, according to Dr. Darwin, is stated as "the unknown medium ("quo pacto adducitur ignoratur") through which the excitement or irritation is produced.

Again, the sentient and fibrous changes which in the Darwinian system of life are thus connected, are not rendered more explicable by the intervention of a subtle fluid. The spirit of animation of Darwin, allowing its existence to be capable of proof, in no measure facilitates the conception of vital causation. As an explanation of the last of the above objections, it may be urged, that when Dr. Darwin, in framing his classification, referred all morbid afection to the heads of irritation, of the voluntary and associative, he seems to have overlooked his former assumption, founded upon the inseparability and identity of the sensorial power or fluid, and not to have been aware he had laid down a principle of action, whether it be called irritability, sensibility, voluntariness, or associability, is only another mode of expressing the quantity of sensorial power residing in the organ to be excited."

The conception of one of these energies necessarily supposes an increase or diminution of all, and the disorder of decreased irritability, ought also to be the disorder of decreased sensibility, voluntariness, or associability. The classification, then, is even in contradiction to the principles of Zoonomia. It is intricate and erroneous.

Perhaps the most consistent and comprehensive plan of arranging individual diseases would be that which, while it preserved the important fact in view, of the indivisibility of the living system, would take into account the three degrees of irritation, or fibrous action, separate, functions performed by the arterial, the nervous, and the glandular organization.

As approaching nearest to this plan, and likewise because it is in most general use in this country, at least for a book for teachers of medicine, we shall make use in the present article of the nosology of Dr. Cullen, requesting the reader to recollect the unavoidable objections which oppose themselves to all systems and all classifications of morbid affections.

The following are the classes, orders, and genera of Cullen, with the exception of the class locales, which relates to those disorders principally that come under the head of surgery.

**Table of Classification.**

**Class I. Pyrexie.** A frequent pulse, succeeding to shivering or horror; increased heat; disturbed functions; prostration of strength.

Order I. Frigidus. Pyrexia, independent of local attention and cause languor, lassitude, and other signs of debility.

Sec. 1. Intermittens. Fevers arising from the insinuation of marshy grounds, with an evident remission, the returning fits being almost always ushered in by horror or trembling. One paroxysm only in the day.

Genera. Tertiana; quartana; quotidian.
MEDICINE.

in ascertained syphilis—

class I. Order I.—Febria.

What is fever? To this question it appears difficult to give a precise and satisfactory reply. It is observed by the author of Zoönomia, that the term fever is given to a collection of morbid symptoms, which are indeed so many distinct diseases that sometimes appear together, and sometimes separately; hence it has no determinate essence, except it signifies simply a quick pulse, which continues for some hours; in which sense Dr. Darwin employs the word throughout his ingenious work.

On this head, however, we differ in opinion with the author just mentioned. An increased action of the sanguiferous system shall be induced sometimes by, and at other times independent of, a diseased irritation, without being accompanied with other peculiar feelings, which, not restricting ourselves to the etymological significance of the term fever, we purpose regarding as necessary constituents of this, as a distinct entity.

In every proper fever, there is a feeling of debility, which essentially differs from actual debility. "A diminution of strength in the animal functions," which constitutes part of Dr. Cullen's definition of the febrile state, is scarcely characteristic of the condition to which we allude. It is a feeling, with which every one is more or less familiar, and appears to indicate rather obstructed than exhausted strength. Dr. Rush endorses this necessary constituent of genuine fever as a distinct expression from simple irritation of the blood-vessels on the one hand, and mere debility on the other, by comparing it with the smothered sound which may be supposed to be emitted from a musical instrument, provided a heavy weight were applied to the chords; which ought to be suffered to vibrate freely and without obstruction, in order to produce a fine musical sound. Another illustration of a similar nature is likewise employed by Dr. Jackson.

Dr. Brown defines fever, "an asthenic disease that disturbs the pulse." In this, however, there is the want of definition which we have just complained of in the definition of Dr. Cullen. Asthenic diseases are diseases of deficient excitement; but in fevers we have an interruption rather than diminution of power. The faculties are locked up, not lost.

Of the phenomena of fever. Dr. Cullen very properly selects the more ordinary circumstances that present themselves in the course of an attack of intermittent fever, as an example of what occurs with more or less regularity in every case of genuine febrile disorder.

The following, he says, "are to be observed in such a paroxysm. The person is affected with laugor or sense of debility, a sluggishness in motion, and some uneasiness in existing it, with frequent yawning and stretching. At the same time the face and extremities become pale, the features shrunk, the bulk of every external part is diminished, and the skin over the whole body appears constricted as if cold had been applied to it. At the coming on of these symptoms, some coolness of the extremities, though little taken notice of by the patient, may be perceived by another person. At length the patient himself feels a sensation of cold, commonly first in his back, but then passing over the whole body; and now his skin feels warm to another person. The patient's sense of cold increasing, produces a tremor in all his limbs, with frequent successors or rigors in the trunk. After which, so long as the cold and its effects have continued for some time, they become less violent, and are alternated with warm flushings. By degrees the cold goes off entirely; and a heat greater than natural to the skin comes on the forehead, and by degrees becomes a sweat, which gradually extends downwards over the whole body. With this heat the colour of the skin returns, and a preternatural redness appears especially in the face. Whilst the heat and redness come on, the skin is relaxed and smooth, but for some time continues dry. The features of the face and other parts of the body, recover their usual size, and become even more turgid. When the heat, redness, and turgescence, have increased, and continued, the skin becomes dry, and a moisture appears on the forehead, and by degrees becomes a sweat, which gradually extends downwards over the whole body. As this sweat continues to flow, the heat of the body abates; the sweat vanishes, and in a gradual manner, the skin returns to its usual temperature, and most of the functions are restored to their ordinary state."

Specia of fevers. Dr. Cullen divides the division of systematics into continued and intermittent. The very correct description above given answers, as we have stated, to a single paroxysm or fit of fever. It is not however often that the chain and continues with the decline of the paroxysm. In the course of a certain time it is renewed; and according to the suddenness or tardiness of the paroxysm's recurrence, the fever is called continued, recurrent, or intermittent. Sometimes, indeed, the disordered actions recur with such celerity, that the fever appears to be one continuous series; "the remission is inconsiderable, is perhaps without sweat, and the returning period is marked by the usual symptoms of a cold stage, but chiefly by the exacerbation or aggravation of the hot one."

The disease in this last case is considered as a continued fever; in which, however, there is thought to be stages of an intermittent, almost invariably, especially in the earlier periods, a diurnal remission and recurrence of paroxysm. Of intermittent fevers, the paroxysms, such as we have just described, are always finished in less than 24 hours, and most frequently are not extended to nearly this time.

We are then furnished with a natural division of fever into intermittent and continued, which however have many circumstances in common, and often pass into each other; thus, what is termed in the schools a quasian intermittent, formed by an interval of 72 hours, and goes from the last paroxysm to the commencement of another paroxysm, will in its course become a tertian ague, with only 48 hours of interval: this again shall fall into a quaquater, characterized by an interval of only 24 hours. A quaquater shall pass into the state of a remittent, and this last be converted into a true continued fever.

Besides, however, this leading distinction of fever, from the times of the recurrence of the fit, we have many others arising from the nature of the constitution of the individuals attacked, the prevailing condition of the atmosphere, and other extraneous circumstances (and, likewise what is ascertained however with less exactness) the specific difference of the exciting cause; thus, common fever has sometimes the inflammatory, at others the typhoid, character. Thus are accounted the fever of damp and warm climates, the yellow fever of the West India islands, the fever of crowded prisons, and the plague in Eastern countries.

On Cullen's genera. It will be perceived that under the appellation of fever we confine ourselves to the consideration of what has been by way of distinction termed simple fever, and perhaps with propriety regarded by Mr. Wilson as "the only general disease," other diseases being either local, or general and local. Thus the sensitive irritated fever of Darwin, which forms principally the pleidogenesis of Cullen, is a disorder either systematic of, or at least supported by, local irritation.

The genera of Dr. Cullen of continued fevers are.

1. Synocha. "Great heat, pulse frequent, strong, and hard; high-colored urines, the functions of the sensorium not much impaired, such changes, not answer to any case of simple fever; it is the definition of what Dr. Brown calls the alethic, which is opposed to the true febrile state."

2. Typhus. "A contagious disease, the heat not much increased, pulse frequent, small, and weak; urine little changed, sense much impaired, and the strength greatly diminished." This definition approaches nearest to the more usual form of fever in this country. That part of the definition, however, is extremely defective which describes the heat as not much increased.

3. Synoachus. This is made by Cullen a kind of intermediate disease between synoachus and typhus.

Exciting causes of fever. On this subject the most opposite opinions prevail. It is imagined by some, that no case of genuine fever, beyond those ephemeral irritations which possibly originate without the previous application, either through the medium of the lungs, or the surface of the body, of a certain something generated in the system of another individual in the course of the same disease. Others infer, from the daily observation of febrile diseases where no communication with the sick can be traced or suspected, that although the febrifacient matter just spoken of be in man, it is not in all instances the cause of fever; that cold, damp, heat, putrid exhalations whether animal or vegetable, insufficient ventilation, the depressing passions, &c. are all, either singly or in conjunction, capable, under some circumstances, not merely of predisposing to, but of actually engendering, proper fever. Lastly, there are some who consider contagion, or the generation of fever by specific febrifacient matter, as totally imaginary; it is a fallacious inappellations in instances where fever has spread by communication, that either certain undetected conditions in the air, or the confined effluvia of animal excretions accumulated by want of

**MEDICINE.**

cleanliness and ventilation, with other circumstances, are causes sufficiently adequate to produce the affection, without supposing the agency of a specific and occult power.

"It is from nastiness," says one of the most celebrated of the anticontagionists, "degenerate into infection by chemical changes, that the bodies, clothes, beds, and apartments, of the poor in Great Britain, derive their poisons, their pestilential charge. By a common paternostive process, the septic exuvia is formed, and derived to some extent from pulsating arteries or glands. Away then with this preposterous phrase, 'from the poison engendered by septic process.'

Let human contagion for the nature mean nothing but small-pox, vaccinated arising in kindred forms of morbid secretions." (Dr. Rush.)

Notwithstanding, however, the circumstances, that they are not met upon, we conceive the general facts to be in favor of poison engendered, independent of mere putrefaction or filth; and we shall shortly state the grounds upon which our opinion is established, without subject of question, in the spread of fever. That contagion, however, is absolutely requisite to the production of this disorder, in every instance, does not seem an opinion authorized by facts, although it must be adduced as a palpable proof; for when we refer to its generation from mere filth and sloth, under the circumstances just mentioned from Dr. Rush, it may be replied, that contagion in such cases may be used in some instances by accident without suspicion, and that the situation of the recipient constituted merely a predisposition to suffer from its application.

A context has likewise arisen respecting the production of intermittent as well as contine-nent fever. Intermittent fevers are observed to prevail especially in situations the soil of which is marshy; on this account it has been imagined, that they are sensibly consequent upon a certain tint or miasma arising from moist ground. "The similarity of the climate, season, and soil, in the different countries in which intermitents arise, and the similarity of the situation of the sick in different regions, concur in proving that there is one common cause of these diseases, and that this is the marsh miasma." (Cullen.) Dr. Brown and others have contended, that the noxious influence of cold or of heat, "when the common ashenhous noxious powers accompany either," are sufficient to occasion genuine intermittent. It however appears an established principle, that intermittent fevers are most frequently the offspring of poison arising from marshes or moist ground. That other causes act in conjunction, and augment the predisposition, is likewise an established fact; for the ages of mortality which occur most abundantly at cold seasons which have succeeded hot ones, and especially amongst those whose diet has been iniminct and unstimulating. It is also beyond dispute that mere cold or poor living will induce symptoms after the habit has been once established.

**Proximate cause of fever.** On this subject the following errors appear to have misled systematics: 1. A want of distinction between final and proximate cause; between inquiries instituted in order to divine the operations of nature, and a careful examination of the phenomena of nature as they occur in sequence. The indivisibility of the body, and the unchangeable constitution of the disorder, have been too much overlooked. Fever has been considered as an affection of parts rather than of the universal system. 3. An error which results from the conjunction of the two former; that shrinking of the coldness of the external surface, which is merely a consequence and concomitant effect resulting from a febrile attack, has been viewed as the cause of the other symptoms which present themselves in the course of the affection.

"The remote causes of fever," says Dr. Cullen, "are certain sedative powers applied to the nervous system, which diminishing the energy of the brain, thereby produce a debility in the whole of the functions, and particularly in the action of the extreme vessels; this debility proves an indirect stimulus to the saguineus system, whence by the intervention of the cold stage, and spasm connected with it, the action of the heart and larger arteries is increased, and continues till it has the effect of restoring the energy of the system, or of extending this energy to the extreme vessels, of restoring therefrom, their action, and thereby especially overcoming the spasm affecting them."

In the historical sketch of the progress of medical theory with which we introduced the present article, we observed that the spasmodic theory of Hahnemann was engendered that of Dr. Cullen. In the hands, however, of this last systematist, the doctrine in question appears to have received modification rather than amendment: Dr. Cullen added another set of entangled links to the previously entangled chain. The shrinking, coldness, and general inactivity, observed at the commencement of fever fits, and which require the necessary consequences of the sudden quiescence throughout the system, induced by the peculiar action of the noxious powers producing fever, our author considers as one of nature's first steps in obtaining relief and obviating the progress of the fever.

On this theory we may in the first place remark, that when the progress of a febrile affection is arrested by remedies applied during the first or cold stage, both the torpor of the brain and the shrinking of the surface may be removed without the intervention of the hot fit. Indeed, obviating the recurrence of this constitutes the cure of fever. The succession, then, of the hot fit is not a necessary consequence of the previous cold; much less is it an agency contrived by nature to remedy this last. The theory is likewise "erroneous, in as far as it enters into the supposed intentions of nature."

Secondly, the action of the heart and larger arteries is hot, as is justly observed by Dr. Darwin, occurred in the mechanical manner of reaction, which the theory we are canvassing supposes. During the continuance of the cold fit, the whole circulation is lessened, or in a manner suspended, the blood is not retreating for safety to the centre, less blood passes through the lungs as well as through the vessels on the surface of the body; the fortress, and not merely the outposts, has been invested by the cold. Now, when the hot fit comes on, the marks of irritation, or as Dr. Brown happily terms it, of "counterfeited vigour," by which it is characterized, are merely consequent upon the natural stimuli acting upon accumulated irritability, of irritability accumulated by the previous quiescence of the cold stage, and are not to be attributed to the blood's reacting and flowing back in order to influence and occupy the parts and cavities which it had deserted. This supposed action and reaction cannot indeed take place in that mode and to that extent which our theorists imagine. The manner of the body is a living and not an hydraulic machine. The blood is not dammed up at one part in order to rush with violence into another. To illustrate: When even a part of the body only, as the hand, is immersed in cold water, then, when the hand is not unexpectedly exposed to a diminished temperature for a short period, a lessened fibrous or vital action is the immediate consequence, the sensorial power or excitability accumulates in a consequent part, and becomes a matter of general sensation; indeed, the hand, if continued in this condition for any length of time, will become quite anaccelerated, but not properly speaking, increased motion, with blear heat, the consequence.

You have perhaps conceded too much to the spasmotic theory of fever, in likening the state of the surface in the cold fit to that produced in consequence of diminished temperature, for in this last the shrinking is direct, while in the former, it is occasioned indirectly, or, as we have previously noticed, is merely one of the effects arising from the general interruption of the functions. Fever does not commence by attacking exclusively the extreme parts, but the capillaries and the capillaries of the surface.

The spasmotic theory of fever then, is not only a substitution of terms for an explanation of facts, but even the phrenology which it employs is out in order to maintain that the leading symptoms of the malady, appears to be deduced from defective knowledge of the laws and qualities of life. It is physically, metaphorically, and practically wrong. "Fever fits are efforts of nature to relieve herself." Darwin.

Before proceeding further, it may be proper to notice one or two defects, as they appear to us, in the ingenious theory of the author of _Zoonomia_. In our remarks on homoeopathy, the mistakes which Dr. Darwin had been led into from his unsound division of sensorial power, were hinted at. These mistakes have been modified; and it is evident in the learned author's attempts to form a sympathetic theory of the disorders under notice: a theory, which, in our opinion, involves the second error which we have above stated, viz., that of overlooking the individuality of the body, or the universal distribution of sensorial power, and regarding fever rather as an affection of parts than of the whole frame. It likewise, by consequence, embraces the erroneous doctrine of attributing the secondary actions in fevers to the cutaneous tachy tera. The cold fit of simple
fever," says Dr. Darwin, consists of a torpor of the cutaneous capillaries, with their mucous and serous mucous glands, which is gen-
tered by direct sympathy to the heart and arteries. The torpor, however, of the heart and arteries is consistent with, and not conse-
quently upon, the injection of the cutaneous vessel; and the power residing in them, for the time at the time of an attack of fever, must be affected in the same manner as the sen-
corial power of the latter; and the admission of association, is the introduction of an un-
necessary law, an additional cause of confusion. That distant parts sympathize with each other, in a manner which physiology has not hitherto been able to unfold, as the stomach with the surface of the body for example, is admitted; in the case of fever, however, we wish particularly to insist upon such sympathy as an explanation of symptoms being super-
fluous: the heart and arteries, the stomach, the surface of the body, the secretory glands, all receive a diminution or sudden interrup-
tion of their functions at the same moment of time, and from the same cause: they are simultaneous and not successive effects. Dr. Darwin seems equally unfortunate in replacing a hot skin and remaining quiescence of some internal organs, as of the stomach, in the second stage of fever, to re-
verse sympathy. Sympatysis cannot be de-

t in one instance, and reverse in another: "The laws of association are irrevocable, or they do not exist."

What then is the cause of fever? It is an abrupt suspension and consequent disruption of all the connected movements of the ani-
mal frame by which the balance of excite-
ment is overthrown, the laws of excitability are changed, and in consequence of which the same agents no longer produce the same

Fever differs from debility insoman as the latter is a gradual and regular ex-
haustion, not an abrupt interruption of the powers of life; it differs from strength of strength consists in a powerful and equable excitement, while fever, however it may "counterfeit vigour," is never attended by the same consequence of vigour, regular and orderly display of power.

The primary cold, or as the Latins term it, "horror," is from the quiescence that has been induced, during this state of quiescence, a new and inordinate condition of the excita-

bility is established, and by consequen-
tion both the external and internal stimuli excite perturbed in the place of orderly and usual actions; action without power commences; hence morbid heat is generated, diseases associations are formed, and without being in a state of actual weakness, the whole sys-
tem sinks, oppressed. The plain indications of

Treatment in fever, are therefore to break the morbid associations on which this op-

pression is caused, or to diminish effects by which it is continued; to diminish the cold in the cold stage, the heat in the hot stage, and not to await the sanative process of nature, 'either of dissolving spasm, or of cooling heat, and expelling morbid cause. The various remedies employed for these purposes are, the external and internal use of cold and warm water; refrigerants, sudor-

nics, opiates, emetics, purgatives; on each of these, we shall introduce a few separate remarks; in the course of which an oppor-
tunity will be afforded, of enquiring more minutely into the pathology of the febrile state.

Of cold and tepid applications, and ablation.—Cold water internally.—Cold air.—The medical reports of Dr. Currie, on the effects of water cold, and warm, in the treatment of fe-

ver, are introduced in the following manner.

Narrative of Dr. Wright:

"In the London Medical Journal for the year 1786, Dr. William Wright, formerly of Edinburgh, published a case of the true and the successful treatment of some cases of fever, by the ablation of the patient with cold water."

"On the 1st of August, 1777," says Dr. Wright, "I embarked in a ship bound to Liverpool, and sailed the same evening from Montego-bay. The master told me he had several sailors on the same day we took our departure, one of whom had been at sick paroxysm on board ship for some time, but in a condition, of very serious state. On the 23d of August, we were in the latitude of Bermuda, and had had a very heavy gale of wind for three days, when the abovementioned man relaxed, and had a fever with symptoms of the greatest malignity. I attended this person often, but could not prevail on him to be removed from a dark and confined situation to a more airy and convenient part of the ship; and as I refused medicine and even food, he died on the eighth day of his illness.

"By my attention to the sick man, I caught the contagion, and began to be in-
disposed on the 5th of September; and the following is a narrative of my case, extracted from notes daily marked down: I had been many years in Jamaica, but except being somewhat relieved by the climate and fatigue of business, I ailed nothing when I embarking. This circumstance, however, might perhaps dispose me more readily to receive the infection."

"Sept. 5th, 9th, 7th: Small rigours now and then; a chilliness of the skin, and a dull pain in the forehead; the pulse small and quick; a loss of appetite, but no sickness at the stomach; the tongue white and sunny; little or no thirst; the belly regular; the urine pale and effusive; and the night relatively clear, with starting and delirium."

"Sept. 8th. Every symptom aggravated; with pains in the loins and lower limbs, and stiffness in the thighs and hands."

"I took a gentle veinot on the second day of this illness, and next morning a desoration of tumar.idis; at bedtime an opiate joined with antimonial wine; but this did not pro-
cure sleep or open the pores of the skin."

No infallible remedy being procured, a drachm of Peruvian bark was taken every hour for six hours successively, and now and then a glass of port-wine, but with no appe-
s. I was bitten upon my deck, my pains were greatly mitigated, and the collier the air the better. This circumstance, and the failure of every means I had tried, encour-
gaged me to put in practice on myself, what I had often wished to try on others, in fevers similar to my own."

"Sept. 9th. Having given the necessary directions, about three o'clock in the after-

noon I slipt off all my clothes, and threw a sea-cloak loosely about me till I got upon deck, when the cloak also was laid aside: three buckets of salt water were then thrown at once upon me; the shock was great, but I felt immediately relieved. The headache and other pains instantly abated, and a fine glow and diaphoresis succeeded; towards evening, however, the same febrile symptoms threatened a return, and I had again recourse to the same plan. The same day, and the same good effect. I now took food with al-
petite, and for the first time had a sound night's rest."

"Sept. 10. No fever, but a little uneasiness about the hams and thighs; used the cold bath twice."

"Sept. 11. Every symptom vanished; but to prevent a relapse I used the cold both twice. Dr. Thomas Kirt, a young gentle-
man, passenger in the said vessel, and of the same profession as his master, on the 9th of August; his symp-
toms were nearly similar to mine, and having taken some medicines without experiencing relief, he was disposed of trying the cold bath; with my approbation. He continued on the 11th and 12th of September, and by this method was happily restored to health. He lives at this time (Jan. 1780) near Liver-

pool."

We have thus presented our readers with this important narration of Dr. Wright, both as it furnishes a history of fever, as it details the mode in which the cold afflictions should be employed. It was consequently the means of introducing this most valuable reme-
dy into general practice. We shall now add from Dr. Currie the more particular rules which ought to govern the use of the affliction in cases of cold water in fevers, and then make one or two observations on the nature of its operation."

"The safest and most advantageous times," says Dr. Currie, "for using the cold water is, when the exacerbation is at its height, or immediately after its declension has begun; and this has led me almost always to direct it to be employed from six to nine in the evening; but it may be safely used at any time after the commencement of the attack. The time of chilliness present, when the heat of the sur-
fase is steadily above what is natural, and when there is no general or projeff porpi-
ration.—These particulars are of the utmost importance in the use of cold water in fevers, and must be used during the cold stage, the respiration is nearly suspended; the pulse becomes flut-
tering, feeble, and of uncalculable frequency; the surface and extremities become doubly cold and relaxed, and the patient seems to struggle with the pangs of instant dissolution. I have no doubt, from what I have observed, that in such circumstances the repeated affusions of a few buckets of cold water with extraneous liquid, this remedy should therefore never be used when any considerable sense of chilliness is present, even though the thermometer applied to the body should indicate a degree of heat greater than 101."

"And neither ought it to be used, when the heat measured by the thermometer is less than, or even only equal to, the natural heat, though the patient should feel a degree of chilliness. This is sometimes the case towards the last stages of fever, when the pow-
ers of life are too weak to sustain so powerful a stimulus."

"3d. It is also necessary to abstain from the use of this remedy under profuse suf-

fused;"
sible perspiration, and this caution is more important in proportion to the continuance of this perspiration." 

"Under these restrictions," our author adds, "therapeutic operation may be useful at any period of fever; but its effects are more salutary in proportion as it is used early. When employed in the advanced stages of fever, where the heat is reduced and the bodily complaint should be given immediately, and the best is warm wine."

Observations. Cold water, as a remedy for fever, may be conceived to operate upon a twofold principle. In the earlier stages, and before the vital power is too much impaired and aggrased and oppressed to endure a violent shock, the copious and sudden affusion of cold water all over the naked body, appears to effect its beneficial purposes in part by the abruptness of its agency; if in a manner severs the chain of disease associations, and restores the healthy and orderly movements of the frame. This operation is not, as has been suggested, mechanical: it is in some measure attended by a rise of temperature from the application of an emetic, to which it is in every respect greatly preceivable, or to sudden mental agitation. In the language of the schools, it causes short fever.

When, however, the disease associations are more firmly established, and the vital power greatly oppressed by the disorder's continuance, although the surface of the body retains its morbid heat, the water to be applied must be cold, not merely tepid or even tepid as to be comforted by the patient, by washing with a sponge, and this under the restrictions enjoined by Dr. Currie, or we may safely say, while it is found genial to the patient's feelings, ought to be resorted to in every case of simple fever. The action of the water at this time is somewhat different from that in the previous period, or under different circumstances of the disorder. It proves a direct stimulus. But how, has it been urged, can the negative of a power prove stimulative? "Darkness might as well be called a stimulus to the eye, or hunger a stimulus to the stomach, as cold to our sense which perceives heat." Darwin.

To this, he replies, Dr. Beddoes, and before him by Dr. Beddoes, that the objection is founded upon a disregard of the sentient principle: "Cold," says the latter author, "may very often be so applied as, by removing the very disadvantageous sense of heat, that attends some diseases, to produce an effect equivalent to stimulation. It is, I believe, exactly in this way, that bathing the body with cold water proves serviceable in low fevers."

From the urgency, however, of the debility, or from the prejudices of the patient or his friends, in some periods of fever, even the application of cold water in the way of ablation may be regarded as too severe. In this case tepid ablation has been made to supply its place, and often with propriety and success; it is, however, particularly deserving of remark, that unless this last be used in the gentlest manner, the object of the practitioner in its choice is defeated, as the evaporation from the surface is more copious from the tepid ablation; and this is one of the most powerful, indeed, strictly speaking, the only direct manner of ablation, which is applied by Dr. Currie to water, from 87° to 97° of Fahrenheit; from 87° to 75° the water is denominated cool. Cold water may be given internally, and with the utmost freedom, in the hot stage of the fatal paroxysm. Its use, however, requires to be carefully regulated by the same restrictions as in the external application; it must not be given unless the heat of the surface be steadily above the natural standard. Draughts of cold water have been known, when properly administered, to procure a sudden solution of the disease.

Cold air. The extraordinary melloration in the modern practice of medicine, as it relates to the treatment of fever and febrile diseases, is not confined to the use of ablation and ablation. The terror of our predecessors, in relation likewise to cold air, are fast departing; and the importance of its free admission in the apartments of the febrile sufferer especially, comes to be generally acknowledged and applied. It has been stated by a physician, above all praise for fidelity of observation and justice of remark, that the corrupted air of sick rooms, is more highly objectionable as being much more fatal even among the higher classes of society, than the virulence of the disease itself. "Vener em cudiam agnoti non tam morbo quo puerorum, quam habitibus putridis, quos diescur dri nume propter amicorum cura." Heberden.

The utility of cold air in fever is referable to two principles: 1st. That of immediately lowering the heat of the surface, and thus tending to supress the occasional accretions by such heat; and 2ndly, from affording a larger quantity of oxygen at each inspiration. The first of these principles is sufficiently evident, and does not require any further illustration: if cold ablation prove beneficial chiefly by virtue of diminishing the temperature of the body, it necessarily follows that coldness in the circumambient atmosphere must be attended with precisely similar effects: but on the purity, as connected with diminished temperature of the atmosphere, it may not be improper to preserve the present opportunity of offering one or two remarks. A given bulk of air at an inferior temperature, contains more of the principle which is essential to sustain life than the same quantity at a superior degree of heat; hence the greater refreshment which is experienced from the inhalation of a cold and dense, over that of a warm and rarefied atmosphere; hence, in part, the more vigorous digestion and keen appetite of a healthy individual during the winter, than the summer months; and finally, by the relief a febrile patient experiences from the inspirtation of such air, it is rendered evident, both that the heat of fever originates, and is kept up, independently of those organs which modern chemistry and physiology have supposed to be the sole organs for the supply of heat to the living system. From this fact Dr. Reid infers, and we think with justice, that the constant equality of animal temperature in a condition of health, has more dependence upon living actions in general than upon a full degree of oxygen in the lungs, according to the ingenious theory first suggested by Dr. Crawford, but since materially modified. See Physiology.

But the frigoric virtue of a more oxygenated atmosphere means the admission into the lungs of a febrile invalid, is a further proof, that however violent the reaction, as it has been erroneously called, such reaction is, in every case of genuine fever, far from being an evidence of actual increase of power. Whatever theory we adopt respecting the precise mode in which pure air influences the animal oxygen as partaken of, it must prevail, that it is, in the strictest sense of the word, an exciting agent. Now as far as it operates beneficially in fever, it reduces the irritant power; that power which actually prevail is from this very agency, which modifies the turbulent action, and by consequence reduces the prevailing morbid heat. The admission of cold air requires likewise to be restricted to the hot stage, and to be limited by the patient's feelings; a current of cold air passing rapidly over the body while in a state of perspiration, may be productive of fatal consequences.

Of refrigerants in fever. Besides, however, the free admission of a cool and pure atmosphere, other agents have been had recourse to, and with considerable effect, in order to abate the morbid heat of fever. From possessing a cooling influence on the system, certain medicines have been distinguished by the term refrigerants: refrigerants are principally chosen from the vegetable acids, and the different neutral salts; and are found in their power in reducing the prevailing temperature, that they have properly been made to constitute a considerable part of regimen in fever. Indeed nitre, and other neutral salts, with the vegetable acids, have been received into some systems of classification, under the distinct head of febriferous medicines. The modus operandi of refrigerants has not perhaps hitherto received explanation; the substances of which they are composed are for the most part those which contain oxygen in a concentrated, and, at the same time, loose state of combination; from this circumstance, their action has been inherently that of perhaps satisfactory accounted for. "It has been sufficiently established," says a modern writer, "that the consumption of oxygen in the lungs is materially influenced by the nature of the ingesta. The fresh air, which is supplied by the respiration through animal food and spirituous liquors, and, in general, by whatever substances contain a comparatively small quantity of oxygen in their composition. But the superior temperature of animals is derived from the consumption of oxygen gas by respiration: an increase of that consumption must necessarily, therefore, occasion a greater evolution of caloric in the system, and of course an increase of temperature, while a diminution in the consumption of oxygen must have an opposite effect. If, therefore, when the temperature of the body is morbidly increased, substances be introduced into the stomach which, containing a large proportion of oxygen, especially in a state of loose combination, and capable of being assimilated by the digestive powers, the nutritious matter received into the blood must contain a larger proportion of oxygen, that principle will be consumed in the lungs, by which means less caloric being evolved, the temperature of the body must be reduced; and this operating as a reduction of stimulus, would diminish the number and force of the contractions of the heart." Murray's Medicina.
MEDICINE.

This reasoning is perhaps more specious than just. In the first place, the remarks which we have above introduced on the actual diminution of febrile heat from inhaling an oxygenous atmosphere, seem to oppose the theory of perspiration as the cause of the oxygenous principle being consumed in the lungs. Secondly, it may be noticed that the effects of these medicines are too speedy and direct to admit of the supposition of this intermediate kind of agency; and thirdly, although the refrigerantia are for the most part, they are not universally, substances which contain this superabundance of the oxygenous principle. The saline draught, for example, appears to moderate febrile heat primarily, by reason of the carbonic acid gas that it contains.

Chemical reasoning has recently been extensively applied to the development of the mode in general in which the functions of the lungs and lungs are connected, and as this enquiry is closely related both to the theory of febrile heat, and the dietetical as well as the medical management of the febrile and the hot fit in general, it is proper to determine the reader by one or two further reflections on this very interesting point of discussion. It is an axiom of Hippocrates, that animal food should not be given in fever; an axiom which was no doubt founded upon observation of its general irritating and disordering tendency. Modern physiology, however, has not rested content with a knowledge of the fact, but has endeavoured to determine its influence upon pulmonary organs. Hence it is said, we are furnished with an explanation why animal diet is uncongenial to the patient in fever. The pulmonary circulation is impeded by febrile oppression, less oxygenous atmosphere, and the power of assimilating materials which contain the hydrogenous and azotic principles in abundance is consequently weakened, or, as we have heard, it expressed still more chemically, less fuel or combustible matter is required, on account of there being less power of consuming such fuel, or of maintaining combustion.

Perhaps the peculiarity or distinct nature of living beings, has not been sufficiently attended to by modern physiologists of the chemical school. That hypothesis, the outline of which we have just delineated, appears at first sight perspicuous and unobjectionable, but when pursued more in detail, facts present themselves which are in some measure at variance with its fundamental principles.

Animal food may, perhaps, prove less congenial to the patient in fever, than under circumstances of debility without febrile disturbance, on account of the direct irritation it communicates to the fibre, independency of its chemical properties, the difference between animal and vegetable diet in this particular, is abundantly obvious. But it may further be urged, that several materials taken into the stomach during the burning heat of fever, appear to be productive of nearly similar effects, in their immediate operation, with a diet of animal food; of this stock, which when duly administered is congenial and salutary, when given while the skin is dry, and there is no disposition to perspiration, proves irritating and harassing; it still further impairs the wound digestive organs, augments the tendency to costiveness, and increases febrile heat. These properties it surely does not possess by virtue of the quantity of hydrogen or azote that it contains.

Of Sudorifics.

We now proceed to consider the agency of sudorifics as febrifuge remedies. Moisture on the surface of the body may be procured by medicines which appear to have a direct power over the cutaneous vessels, or by those whose action seems to be directed primarily to the stomach. These last are principally of the saline class, which are by far the most suitable for this purpose. The physiology of perspiration, and the principles by which it operates as a cooling process, are, notwithstanding the recent discoveries in chemistry, and their application to this interesting subject, still involved in much obscurity.

The ancient imagined, sweat to be not merely an excrementitious product, but the vehicle of conveying that portion of the body which has been the occasion of disease. This opinion does not, in the present state of science, require to be confuted. The questions of most interest, to this interesting subject, respecting the phenomenon and cause of perspiration, are, in what relation does it stand to the respiratory function; and is that moisture on the surface of the skin which closes a febrile paroxysm, to be regarded as a cause or consequence of the disorder's diminution?

"That an animal," says Dr. Currie, "possesses to a certain extent the faculty of rendering sensible heat latent, or, to speak more philosophically, of changing calorics from a free to a latent state, in cases in which the stimulus of heat might otherwise overpower the living energy, there is reason to believe, from a variety of experiments and observations, and that this is in part performed by perspiration from the surface can scarcely admit of a doubt. The process of perspiration, which is continually going on from the surface of the body, is in this point of view the converse of respiration; as in respiration, air is constantly converted into a solid or fluid, and thus heat evolved, so in perspiration a fluid is constantly converted into a vapour, and thus heat is absorbed. A vessel is placed, and exposed to the atmosphere, cannot be raised above 20° of Fahrenheit by any quantity of fuel, because, heat is applied from below, evaporation carries it off from the surface; in like manner we may suppose the heat of the living body to be kept uniform, by the evaporation from its surface increasing or diminishing, according to the quantity of heat extracted from the system, or received from the surrounding medium."

These speculations are beautiful and highly ingenious. It however admits of question, whether Dr. Currie, in applying them to the subject of febrile heat, may not have given too much weight to the analogy of absorption of caloric to animal matter, the excretion of the cooling process in the living body; and whether sensible perspiration, produced by medicine or otherwise, may not be consequent upon, rather than prior to, the diminution of febrile heat? But, for example, a large quantity of water be swallowed in the heat of a febrile paroxysm, and be directly succeeded by general diarrhoea, or sweat, with relief from the burning sensations of fever, although it be natural to attribute such relief to the sweat that is produced, this last may be subsequent to that altered condition of the fibres by which the evoluction of caloric is diminished. Such an opinion has been ingeniously argued by Dr. Reid: and if the following observations of Dr. Darwin are just, they appear to place the matter beyond dispute.

"The perspirable matter," says this latter, "is secreted every second quantity during the hot fit, the hot fit begins to decline, their increased action lessens, and hence the abstraction of sweat is diminished, whilst the increased secretion of it continues for some hours afterwards, which occasions it to stand in drops upon the skin. As the skin becomes cooler, the evaporation of the perspirable matter becomes less as well as the abstraction of it. And hence the dissipation of aqueous fluids from the body, and consequent thirst, are perhaps greater during the hot fit than during a cold one.

For the sweats do not occur, according to Dr. Alexander's experiments, till the skin is cooled from 112 to 108 degrees of heat; this is till the patient is in a decline to their increased action lessens, and hence the abstraction of sweat is diminished, whilst the increased secretion of it continues for some hours afterwards, which occasions it to stand in drops upon the skin. As the skin becomes cooler, the evaporation of the perspirable matter becomes less as well as the abstraction of it. And hence the dissipation of aqueous fluids from the body, and consequent thirst, are perhaps greater during the hot fit than during a cold one.

It appears that the sweats are not critical to the hot fit, any more than the hot fit can be called critical to the cold one, but simply that they are the natural consequences of the decline of the hot fit. And hence," continues our author, "it may be concluded, that a fever fit is not an effort of nature to restore health, but a necessary consequence of the previous torpor; and that the causes of fever would be less detrimental, if the fever itself could be prevented from existing, as appears in the cool treatment of the small pox."

Of Paracetemol and Emetics.

Nothing, perhaps, is of greater moment in almost all afebrile and every kind of fever, than to preserve the whole of the alimentary canal free from accumulations of colics, &c. From a deficient attention to this principle, since the introduction of the card to the treatment of this, and indeed in a variety of other diseases. Viscidities and impurities in the sto-
march and bowels, are often both effect and cause of the persistence of the febrile state; for the inflammation is always first excited by the induction of fever, so the consequent accumulations of foreign matter in the alimentary and intestinal canal, themselves prove direct sources of irritation and disease. In the ordinary stages of fever, an emetic has been known abruptly to arrest its progress, and the same purpose is sometimes accomplished, especially in ephemeral affections of the intestinal kind, by the employment of a brisk purgative. In the more advanced periods however of the disorder, the object of the physician ought to be rather that of keeping the bowels gently open, and this is best effected by saline in place of a saline purgative; the former of which principally operate by exciting the exhalants on the internal surface of the intestines to pour out their contents, the latter by stimulating in a forcible manner the intestinal fibres.

It is a fact worth particular notice in the treatment of fevers especially, that where as due attention is given to ensure regular evacuations from the bowels, those stimuli, the copious use of which is often necessary to support the attacks of fever in the last stage of the disease, are more freely admissible and abundantly more efficacious: this is indeed an important principle in the treatment of diseases generally; and it is perhaps chiefly by virtue of this rule, that in an orderly and due condition for the agency of other stimuli, that purgatives, like sudorifics, form so useful, and indeed the former, almost an indispensable part of the regimen of the greater number of ailments. In intermittent fevers it is generally necessary to evacuate the bowels by more stimulant cathartics, more especially when the cure of these fevers is conducted by the Peruvian bark.

Having thus discussed the nature, causes, and treatment of fever, it may be proper to present the reader with a recapitulatory view of the remedies which are required in the different stages of the disease; but more particularly, to such recapitulation, we shall make one or two remarks on the more unfavourable symptoms with which fever is sometimes attended, and on the periods in which the disease works a greater or less duration to terminate.

The unfavourable signs are, in the first place, an abrupt alteration of type. If during fever, indicating in its primary stages no particular severity of disease, a rapid change take place in the feelings and expressions of the invalid; if upon the more ordinary symptoms, suddenly and unexpectedly supervise delirium, prostration of strength, an observable change in the primary stages of fever, accompanied by irregular and partial alternations of heat and cold, without the intervention of the perspiring state, the patient's life is in considerable danger. These above changes are often indeed preludes to a speedy death. Weakness, quickness, and irregularity of pulse, delirium, tendency to fainting when in an erect posture, prostration of strength, partial and irregular sweats, difficult respiration and cyanosis of the tenens, unusual fever in the excretions, great faintness of the tongue and fauces, are all evidences of a fatal tendency in the complaint; in general likewise it may be observed, that in cases where marks of great nervous irritation are absent or of a fever, even though the disorder may not assume that has erroneously been termed the putrid type, much danger is to be apprehended. Indeed, the management of fever is not to be recommended or the indications of treatment less decided, from the absence of such type. Genuine nervous fevers are often the most obstinate and malignant.

Reverses of this kind, indeed, the heat is often so partial and irregular as not to admit of the cold affusion. Dr. Currie in his Medical Reports, describes a fever in which this remedy was tried without success. This fever, says Dr. Currie, does not appear to originate in contagion, or to be propagated, by contagion.

Calculations respecting critical days have been in some measure forced and systematized. It is worthy however of remark, that the critical days and fever, as well as intermittent in the successive stages of their course, are disposed to assume progressively the quidian, tertian, and quartan aspect.

Thus, if in the first or second day there be more than a week, the ninth and eleventh days from its first attack are those on which we may anticipate its declination; after the second week the seventeenth and twentieth are the more usual period of termination. These however, are by no means unexceptionable rules.

RECAPITULATION OF THE TREATMENT OF FEVER.

Treatment of continued fever during the first three days. Cold affusion. Water to be impregnated with salt, its application to be confined to the hot stages of the paroxysm. Large draughts of cold water taken under the same limitation. Cold and pure air. Emetics. Purgatives. Aperient and saline infusions.

After the fifth or sixth day, Cold and tepid ablation. Water employed to be impregnated with salt or mixed with vinegar. In the morning two glasses, or dilute alcohol, camphor, pudicium, or the warm bath. Bowels to be kept gently but constantly open, by saline or mild purgatives and subacid drinks. While the skin is preserved moist by these medicines, these last, or any other, which are almost invariably improper when the skin is dry and hot, and the bowels costive. For head-ache and other nervous affections, blisters, ether, camphor. In the last stages, when critical sweats break out, and the powers of life appear to be shrinking from the contest, repeated glasses of port wine with mixture of opium in large quantities. During the whole course of the disease, the appearance to be diligently preserved cool, clean, constantly ventilated, and free from all individuals but those who are necessary attendants on the sick.

TREATMENT OF INTERMITTENT FEVER.

Cold affusion immediately upon the full accession of the hot fit. Warm bath, warm spiced wine, during the cold stage of the paroxysm. Tincture of opium, either previous to the accession of the cold, or towards the decline of the hot fit, and immediately preceding the accession of the paroxysm. Calomel purges before the administration of tonics; arsenic, zinc, Peruvian bark, quassia, and if any enlargement of one of the viscera (ague cakes) appear, sted. Hope; upon the expectation of hope the power of clausus altogether depends; these sometimes succeed in ague, when other remedies are contrariwise by the violence of the complaint.

Although we have judged it expedient to enumerate the different medicines which in the event of fever's protection may be requisite, it is proper to observe that the progress of the complaint may be for the most part be abruptly arrested, and the necessity of other means of cure consequently superseded, by an early and judicious employment of the cold affusion. If the application of the water in the mode described in the narrative of Dr. Wright he objected to, a slower bath may be employed, or, what is an excellent and convenient substitute for the latter, a common gardener's watering-pot; the patient is to be taken out of his bed, if convenient, conducted or carried into an adjoining apartment, and the water poured from this instrument as hastily as it will admit of over his naked body; the skin is then to be quickly and effectually dried with towels, and the invalid re-conducted to his bed; this course of treatment is to be continued with the application of the hot paroxysm, even should this be on the same day, and continued, if requisite, on the following days, until the disorder's decline; or, in the pointed language of a modern writer, "the evil may be swept away." (Reid's Medical Reports, Monthly Magazine.)

Fever Houses, &c.

The rapid and extended diffusion of fever through families and individuals might be deemed sufficient evidence in favour of matter engendered by febrile action, having the power to produce a similar disorder in another individual. The fact, however, appears to have been placed beyond doubt by the unfortunate result of several experiments made with sceptical tenacity in order to prove the negative of this assumption.

While the writer of the present article was published in his article on fever at the medical university, several anti-contagionists, as those gentlemen were denominated, freely exposed themselves within what they regarded the imaginary sphere of contagion, in the wards of the infirmary of the university; and they observed that once these individuals were infected with fever, and in some instances the disorder had a fatal termination. In these instances the production of the disease could not be referred to want of cleanliness, or to any peculiar condition of the atmosphere; for the fever did not extend to those gentlemen attending the hospital, who were fortunate enough to remain satisfied with the previous evidence in favour of contagion.

But with a knowledge of the evil, we have at length acquired a knowledge of its antidote; and it has been demonstrated by experiments upon a multitude of the male and female, that, whether the matter producing fever be introduced into the system by the lungs, the surface of the body, or the stomach, its power to infect extends but an exceedingly small distance—three feet at the most; and the patient in whom it is generated, "when he is confined where the air has free entrance and egress." This fact, it has been well observed, "cannot be corroborated by too great a variety of testimony, nor repeated too often, until it shall..."
be familiar not only to the most learned of the profession, but well known to the community at large." (Dr. Bateman.)

Its application with that of another fact immediately to be mentioned, has already gone a considerable way towards the actual extirpation of contagious fever.

This second fact is, that although infectious matter be rendered almost immediately inert by exposure to the air, it is capable of being rendered concentrated, and even transported at an unlimited distance, when made to come in contact with any material, even "a rag or a bit of lint," if such material be excluded from the air. From these, one should expect unquestionable premises, separate receptacles, apartments, and houses, have been exclusively devoted to the admission of the sick in fever, and, as we have just observed, with the most evident and extended benefit, particularly to the inferior classes of the community.

The example of fever institutions was set to the metropolis by the very active and laudable exertions of provincial physicians. In being thus hitherto a Companion, Liverpool, Cork, and other large towns in the British isles, the plan of thus separating the infectious fevers from other diseases, had already been adopted, and at length its extension, and was found in New York, in London, and with the happiest effects. Among the internal regulations of these houses, the following are the most important—they have been adopted in this country, and are now considered essential, and apply in a general manner to private practice.

Every patient when admitted into the house, is to change his infections for clean linen; the face and hands are to be washed clean with warm water, and the lower extremities fomented. "The effect which this salutary change has upon the patient before any medicine is given, is often more beneficial than those which all the antihypertensive drugs in the world could better." All discharges are to be speedily removed. The floors of the sick room are to be washed twice a week, and near the beds every day. The clothes which the patient brings with him are to be thoroughly purified by washing the linen, and exposure for a length of time of the other habiliments to pure air.

Blankets and other bed-clothes are to be exposed to the open and fresh air before they are used by another patient. Several windows of the apartment are to be constantly opened in the day, unless the weather is very cold and wet; and some of them should not be shut in the night, if the patients are numerous, and the weather moderate.

By a due enforcement of these regulations, the necessity in general may be obviated of employing the acid fungicides recommended by Chestworth, Carmichael Smith, and others, which have been ingeniously, and we think justly, imagined to operate upon the same principles with atmospheric or pure air, viz. by oxidizing, and thus destroying the various fungous effusions.

By cleanliness then, and procuring a free circulation of air, by guarding against the lodgment of contagious matter, and by keeping as much as possible from actual contact with the sick in fever, every cause is obviated from which infection can be communicated. The individual who resides in the house adjoining to a fever institution is equal-

ly out of the sphere of contagious influence with one at fifty miles distance; may, in the contagious apartment, and even in the sick room itself, the immunity is precisely the same: such are the preventive as well as the experimental effects of cleanliness and ventilation, which, whether in sickness or in health, cannot be too highly appreciated, or too extensively adopted.

**ORDER II.—Phlegmasia, Inflammations.**

When any part of the body has an unusual heat and redness, with pain and swelling, it is said to be in a state of inflammation, and such a state of a part, an inordinate action and disposition of vessels have generally been esteemed sufficient. Such opinion, however, has been questioned by the author of Zoonomia. "Inflammation," says Dr. Darwin, "is uniformly attended with the production or secretion of new fibres, constituting new vessels; this, therefore, may be esteemed its essential character, or the criterion of its effects. At the old parts of the body, where the reaction seems rather a consequence than a cause of the germination or pulsation of these new ones; for the old vessels may be enlarged and excited with unusual energy, without any production or secretion as in the head of name or of anger." On the contrary, however, we are disposed to regard the formation of new vessels, which does not perhaps take place in every case even of genuine inflammation, consequent to the wound, or the occasion of capillary dilatation. The case which Dr. Darwin puts in opposition to this theory is not in point. It is permanent and forcible, not transient and slight, extension of blood vessels, which constitute the inflammatory state. The eye may be exposed to a vivid light, its vessels consequently act with more than ordinary excitement, and this to a certain extent without actual inflammation; but if such excitation be extended beyond a certain point, the small vessels of the organ shall be deprived of their proper resistance, and thus shall not merely transmit a more than the quantity of blood, but shall in a manner become congested in their vessels, and shall cause pain, unusual redness, heat, and tumour. This induced weakness of the capillaries, ought then, perhaps, according to the opinion of some authors, to be regarded as the proximate cause of inflammation; the too great or too little excitement on which it may have depended the remote cause; and the increased action of the larger vessels of the part, the proximate effect.

The augmented action, if considerable, is accompanied by an irritation of the whole system; such irritation constitutes the "senitive irritated inflammation"—Dr. Darwin, who is distinguished from simple, or what we have considered genuine fever, by its being a sequent of local affection.

**Sthenic and asthenic inflammation.** The disturbance of the System does not correspond more with the magnitude of the local disorder, than with the constitutional character of the individual affected. Of two persons that are the subjects of inflammation, as of the mucous membrane of the nostrils, constituting inflammatory catarrh, or a cold; of the serous vessels, of the adjacent organs of the lungs; or of the joints, forming rheumatism; one shall previously have possessed much constitutional vigour, the other shall have been languid and feeble—the former will have a sthenic, the latter an asthenic disease. This distinction in practice will be found of immeasurable importance. It was of the utmost consequence to Dr. Darwin, and we believe, however, that this author was mistaken in the mode in which the inflammation of a part, and the disorder of the system, are connected; for the purpose of cor-

firmed his favourite theory of atheistic and asthenic disorder, he laboured to prove that the systematic in many cases of inflammation actually preceded the local disease—this is not the case. Even in the most violent fevers of pulmonary origin, Dr. Darwin says, "the lunge precedes that of the system; and indeed asthenic disorder, independently of local irritation, is in some measure a contradiction in terms. High excitement, to whatever extent it may be carried, while there is no irregularity of want of balance in any of the corporeal or mental function, and no affection of a part, cannot be properly regarded as a disease, however it may predispose to the disease of the system."
MEDICINE.

141

as of the lungs. For example, in small-pox
and in measles, we shall have the same degree
of inflammation of the skin, the burning of the
mouth, and cold air would be equally indicated in either, were we to
infer the proper method of treatment alone from the inflammatory excitement;
but in measles the lungs are often the principal
seat of the local affection, an oxygenous
or pure atmosphere would prove too stimu-
lating to these organs, and thus if we pur-
sue general doctrines without particular ex-
ceptions, or overlooked the peculiar na-
ture of the part or organ injured, the object
of our plans would be frustrated and de-
feated.

As it relates to this important principle in
medicinal agency, the system of Dr. Brown
is exceedingly deficient. The peculiar sus-
ceptibility of the separate organs our author
overlooked in the rapid and general survey
which he took of the animal economy.

Genus I. Pulmonary, inflammation of the
lungs.

Species 1st. Cynanche tolistallis, a com-
mun inflammatory sore throat.

M. M. Acid gargles. Saline purgatives.

Species 2nd. Cynanche maligna. An acci-
dental, but very common, symptom of scar-
let fever. See SCARLATION.

Species 3rd. Cynanche trachecialis, croup.

See Infancy.

Species 4th. Cynanche pharyngea, a more
extensive in the pharynx of the cynanche
tolissalis.

Sp. 5th. Cynanche parastrachea. The mumps
manifestation of the parotid and maxillary glands,
which appears in the form of a swelling under
the jaws: it is more common in some than in
other counties of England. It sometimes
appears as an epidemic. The mumps is in
itself a slight disease; but after its declension,
which is in general about the fourth day, the
tests in men, and breasts in women, are very
apt to be affected with swelling, in conse-
dquence of some peculiar sympathy of these
parts with the throat.

M. M. If delirium supervene upon the
retrogression of the swellings, blister. "To
suckle the head with warming water." Darwin.

Genus IV. Pneumonia, inflammation of the
lungs.

Genus V. Corditis, inflammation of the
heat or pericardium.

Genus VI. Peritonitis, inflammation of the
peritoneum.

The disorder which is usually termed
inflammation of the lungs varies in some mea-
sure its seat. Thus the diseased action shall
be directed towards that part of the pleura
which is irritated, and the blood, which may
be called carotis; or it may pass down the
diaphragm, or the peritoneum, and form the
peritonitis of Cullen, the diarrhagitis of
Darwin.

The general symptoms are, pyrexia, pain
in the chest, and deadly symptoms of the
heart, and, if the disorder happens in the
stomach, the pulse is hard and frequent.
Sometimes the expectation is tinged with
blood.

The particular symptoms are, in caroticis,
palpitation, with unequal intermitting pulse,
pain in the region of the heart, vomiting,
fainting: if the inflammation be particularly
directed to the diaphragm, the pain is situated
towards the lower ribs; the respiration in a
recumbent posture is extremely difficult, and
the corners of the mouth are sometimes so
retracted as to form a disagreeable smile,
called rima sardonicum.

M. M. It is of the utmost importance to
attend to the prevailing diathesis. If the
constitution be shenic, and the disorder ur-
tant, immediate and exact remedies are
required; for, with such a disposition, the
frigant and emollient cathartics. Cool and
equal, not cold and irregular, atmosphere.
Dilute drinks. Total abstinence from an-
imal food, sometimes during the first five
days. Antimonial preparations. Avoid compres-
sing it a blister on the painful part. Digitalis. In
Dr. Currie's Medical Reports we find the fol-
lowing observations: "I have employed the
digitizs to a very considerable extent in in-
flammations of the brain, of the heart, and
the lungs; and have succeeded with it in
cases where I otherwise should have despaired."
In Dr. Reid's Treatise on Consumption we meet
with an acquiescence in this sentiment on the fox-glove. Our experience,
however, has taught us to value this remedy
principaliy in other pulmonary affections than
the more violent kinds of inflammation, as
is mentioned under the head of phthisis. After
the excitement has been moderately, opium
in small doses. "Do neutral salts increase the
tendency to cough?" Podalivum. Small
doses of calomel, to prevent adhesions.

N. B. If pneumonia run on into suppura-
tion, we shall be discharged by cough, and
thus a species of consumption be formed; or
will be detained in the cavity of the chest,
and constitute cementum. In other cases, di-
gitalis in large doses. Calomel. Optimum:
Pervian bark.

Genus VII. Gastritis, inflammation of the
stomach.

Symptoms. Violent pain in the region of
the stomach, with pyrexia; small, frequent,
and sometimes contracted, pulse; vomiting;
laugh.

Causes. It may be occasioned by any thing
acid taken into the stomach; by blows on
the region of the organ; and a slight species
of it is often consequent upon taking cold in-
quiries after exercise.

M. M. In inflammation of the stomach
and bowels we have, in some measure, an
exception to the general rule of curative ac-
ting as the disease appears sphenic or a-
henic. The pulse and vital powers are often
udently reduced, and yet venesection is re-
quired. Warm bath. Fomentations. Ano-
MEDICINE.

Genus XII. Cytisus. Inflammation of the bladder.

Genus XIII. Hysteris. Inflammation of the womb.

Heat, pain, tension, and swelling in the lower belly; pyrexia; vomiting. M.M. Venesection. Mucilaginous clysters, with opiates. Anodyne tonifications.

Genus XIV. Rheumatisma. Rheumatic inflammations never, like others, terminate in suppuration. Dr. Darwin attributes this circumstance to the secondary and associative nature of the disease; the original cause, like that of the gout, not being in the inflamed part; and therefore not continuing to act after the inflammation, continued action of the hands at a distance would be more properly referred to the nature of the parts that rheumatism attacks.

Division. Rheumatism is sthenic, or asthenic: the former, chronic rheumatism, often succeeds to the former; which the author just quoted refers to the deposit of nucos, or coagulable lymph, which the inflamed vessels had poured out in the first stages, remaining absorbed on the synovial membrane of the joints. It would probably be more correctly attributed to the loss of energy in the parts affected: an opinion which appears to receive support from the circumstance of the asthenic form of the complaint sometimes coming on in a direct way, without the intervention of the acute species.

M.M. Bleeding would appear to be indicated in the sthenic kind of rheumatism; in this disorder, however, the physician is so often unexpectedly foiled by the rapid occurrence of indirect debility, that venesection is almost never advisable; it lays the foundation for obstinate chronic complaint. Leeching to the joints, and taking a cold bath after the inflammation has in some measure subsided, Calomel, and opium. Sudorifics. Warm bath. "I have found digitalis an excellent remedy in inflammatory rheumatism, one of the most tedious and incurable of all diseases." Dr. Currie.

Genus XVI. Podagra, gout.

Symptoms. Pain in the joints, principally the great toe, and, with it, stiffness of the foot and feet, returning at intervals. Previously to the accession of the inflammation the muscles of the stomach are generally disturbed. The fits generally come on in the morning.

Causes and peculiarities. Gout is invariably a disease of the asthenic diathesis. It is produced in a system predisposed to its influence by the indirectly debilitating powers of certain vegetables and watery food, depressing passions, &c. The inflammation of this disease often alternates with, and appears in a manner vicarious of, torpor in other parts of the system; as of the brain producing delirium.

Dr. Darwin supposes the original seat of the gout to be the liver, which is probably affected with torpor not only previous to the annual paroxysms, but to every change of its situation from one limb to another. For this principle of associate action there does not, however, appear sufficient support; and indeed the sympathy is displayed with more force and frequency between the liver and the foot, than we have before mentioned (the stomach, the lungs, the brain), than the hepatic viscera. It is indeed the nervous system, and not the glandular, with which the paroxysm of the gout appears to have the most intimate connection; and it would have found a more appropriate place under the head of nervous diseases, that where it now stands in the Nomenclature. It is, however, very often combined with calyceal inflammation of the bladder.

The gout is evidently hereditary; but the attacks of this malady may, in general, be warded off, even from the most susceptible habit, by a temperate mode of living. This principle is illustrated in an extraordinary manner by the history of Dr. Gregory, the present professor of the practice of medicine in Edinburgh. We have often heard him in his lectures produce his own as an instructive case of the beneficial effects of abstinence from fermented and spirituous liquors. Gout has been imagined, like fever, to be a savant process of nature, for the purpose of expelling something from the constitution. The doctrine, in either instance, is equally erroneous.

M.M. In treating gout it should never be forgotten that it is an asthenic disease: white excitement is kept up in the system by paroxysms are suspended. Dr. Beddoes, in his Illness, says, that one of the greatest marvels to gout he ever met with informed him, "that his freest year was that of a warm, contested election, at which he was candidate for a county. He both drank and exerted himself at this time more than at any period of his life." This evident principle of the asthenic nature, even of the actual inflammation in gout, ought to render the physician extremely careful in his applications of the remedies lately introduced into practice, the application of cold water to the inflamed part, in some violent cases this may be proper; but it should never be extended beyond the limit of pleasurable sensation. To bless is like to curse, for the mode of suspending the paroxysms has already been referred to; and every artifice experiences temporary benefit from his dinner, his glass, and pleasurable company. It
MEDICINE.

143

is by acting on the imagination that empires suspend the threatened attacks of gout. In this, as in many other instances, constitutes the virtue of remedies; both therefore in chronic rheumatism and gout, we might place among the curative agents metallic tractors, whether authorized by Paracelsus, or formed of old nails, as in the instructive experiments of Dr. Haygarth. Even a piece of scaling-wax, or stick, when supposed by the patient to be the genuine tractors, operated in a most astonishing manner. (Haygarth on Periarthritis.) The influence of the imagination over the body, whether in health or disease, has not been sufficiently acted upon in the professional practice of medicine. The irregular affections in gout must be combated by stimulants carefully adapted to the excitability; for the spasmodic affections of the stomach areatics and bitters, as ginger and quassia. If the head is affected camphor, muri, ether, opium; these like wise are remedies for the humors. The Portland powder, which is a composition of bitters and aromatics, may prove for a time highly useful; but the protracted use of medicines of this class is objectionable, as eventually detons stomach and bowels. Regular and steady, and not capricious and merely temporary, abstinence from wine, spirits, and spices. The body to be preserved gently. Pure air, moderate exercise, cheerful mind, in a Warm and cold sea-bathing. Bath waters. Very small doses of digitalis. Hop (humulus lupulus)?

ORDER III.—Exanthemata, Eruptions.

The exanthemata are more nearly allied to genuine fever than those disorders of which we have just been treating, as the local affections are consequences rather than symptoms of the general irritation. They have been called eruptive fevers. They are defined by Cullen contagious diseases, affecting a person only once during the whole of life, contracting with fever, and succeeded by eruption on the surface of the body, upon which these depend may indeed operate upon certain parts more particularly, and thus the disease be entitled to rank among the sensitive, irritative, or symptomatic fevers. The eruption is by no means the primary indication of the exanthemata: the primary action of contagion, whether of a specific or general nature, has hitherto escaped the penetration of the pathologist.

Genus I. Ermplies, St. Anthony's fire.

Symptoms. This disease does not correspond with the whole of the above definition; it is not contagious; and it has frequently been found to recur. The disease is more ordinary seat of this affection. After febrile irritation has subsided, and continued for a short time, during which there is often an unusual dryness, and sometimes delirium, the face suddenly becomes bloated, the eyes lids swell, and the skin is red and blistered. If the disorder is violent, or ill-treated, the inflammation and redness extend down the neck, and spread so on times on the shoulders: the tuft appears more discolored, and sometimes hemorrhages, and the patient has been known to die apoplectic. The erysipelas is an exanthematic inflammation. Its seat is the retic mucous. Its tendency is to gangrene, rather than to suppura- tion. A fatal termination is said to be principally on the 7th, 9th, or 11th day.

M. M. In no other affection is it of more urgent moment to decide on the treatment by the nature of the prevailing diathesis. It has been observed, that in large and populous towns, Measles appears in the form of asthenia; and in this case requires wine, bark, opium: while in the hardy constitution of the rustic it assumes a sthenic character, and demands the vigorous emollient. It is in the latter that remedies become the object of the physiologist. Venusenosis. Saline purgatives. Ditter drinks. Might not digitalis be employed with a propect of singular advantage, as the disease has an evident their pertinence of species? With respect to external application, it has been customary to use meaty substances, such as flour. Solutions of lead, zinc, or alum, are improper, "as they stimulate the secreting vessels into too great action." (Darwin.) Cold water.

Genus II. Pestis, the plague, an epidemic typhoid fever.

Genus III. Variolata, small-pox.

Symptoms. After the pyrexial symptoms have continued for three days eruptions appear on the skin, which on the eighth day begin to appear. Species. The small-pox is divided into the distinct, and centrifugal. the first has more of the sthenic, the latter of the asthenic, character. In the former the eruptions are of a phlegmonic, in the latter of an erythematous spreading, nature. The eruption of the distinct small-pox makes its appearance in circumscribed red spots on the face; in the course of two days the body and legs receive their characteristic spot. If these, the face swells, the pustules enlarge, and on the eighth day are mature. The swelling of the face now goes off, and the hands and feet begin to swell, with a slight return of fever, which however soon declines.

In the continent, or asthenic, species, the fits are not so regular; the eruptions are not circumscribed and prominent, but diffused, and scarcely appearing above the skin; a lacerated appearance. The eyes swell, the throat, and every symptom denotates debility. The fatal termination is often on the 11th day.

Incubation. The advantages of inoculation for the small-pox need not be insisted on. The circumstance, however, upon which depends the more favourable character of inoculated over natural small-pox, does not appear to have been satisfactorily accounted for. The only caution requisite in preparing for inoculation, are to preserve the three fingers' breadth, always a space for the insertion of the matter when feeling, or other irritable processes, are not going on in the system. With respect to the time, it has been well said, that inoculation ought to be performed either before the second month, or alter the second year.

M. M. Cold air. The bowels to be preserved open. Animal food to be denied. If the fever runs high, antimonials and nitre. In convulsive fits, barbituric acid, and when the internal canal is with the utmost solicitude to be preserved free from congestions by purgatives, the bark, small doses of nitre, wine, pure air; vinegar aspirated about the head, veins, and floor of the apartment. Pericardium.

N. B. For an account of the vaccine disease, see the article Vaccination.

Genus IV. Varicella. The chicken-pox is a very slight disease; the eruptions sometimes assume nearly the character of the distinct small-pox; but there is not much irritation of the system, and they generally disappear in the course of three or four days from their first breaking out.

Genus V. Rubella. Marks. Symptoms. Pyrexia, sneezing, inflamed eyes, dry cough, drowsiness; about the fourth day, or later, small red points appear on the skin, which in the course of about three days fall off in branny scales. "As the contagious material of the small-pox may be supposed to be diffused in the air like a fine dry powder, and rising with the saliva in the mouth to infect the tonsils in its passage to the stomach, so the contagious material of the measles may be supposed to be more completely dissolved in the air, and thus to impart its poison to the membranes of the nostrils which contains the sense of smell; whence a catarrh with sneezing ushers in the fever." Zoonia. Measles.

M. M. Measles too often lay the foundation of pulmonary consumption, to prevent which the symptoms demand inflammation of the lungs are to be with much solicitude observed; and for this purpose small doses of mixture of digitalis are to be preferred to every other medicine. Venusenosis cannot with propriety be used, however, imperiously called for; and digitalis supplies its place without the risk of inducing indirect debility. Steady and cool atmosphere, not cold air in currents. Refrigerant cathartics, with calomel. Animal food, not to be given. Digitalis, with a very small quantity of opium, for the cough succeeding to measles.

Genus VI. Miliaria, military fever, is merely a sympathetic eruption. Small points appear about the neck and face, which in two days become white pustules, and desquame. They have a peculiar smell. Much anxiety and difficulty of breathing precede the eruption. This disorder appears to be a consequence of an improper heating regimen in fever.

Genus VII. Scrofula, scarlet fever.

Symptoms. After pyrexia has lasted about four days a scarlet eruption appears on the skin, sometimes attended with inflamed tonsils and cervical glands; these last sometimes appear without cutaneous eruption, and the disease has been called scrophularia malignant. This disorder is apt to be mistaken for measles; but in scarlet fever there are no catarrhal symptoms as in measles. This disorder is very irregular in its aspect; and often, without much care, fatal in its termination. Sometimes, without any alarming symptoms in the onset of the fever, a change takes place, and in the course of a few hours the patient falls into the arms of death. The unfavorable symptoms are the same as in the previous form, but more principally of children. Whether it depend upon an affection, like measles and small-pox, is not perhaps utterly ascertained.

M. M. Cold air. Air. Antimonials, opium, bark, wine, saline purgatives or cinemas,
of some other discharge, such discharge to be restored.

Genus II. Hæmoptysis. Spitting of blood. Symptoms. Redness of the cheeks, a sensation of weight in the breast, difficult respiration. Slight taste in the mouth, irritation in the trachea, coughing up of florid blood.

Hæmoptysis more usually appears in individuals with a slender make and contracted chest, who are of an irritable habit, and who have been subjected in their earlier years to epistaxis. It generally comes on at the age of puberty.

Causæ. Violent irritation of mind or body, sudden vicissitudes of heat and cold, too powerful excursions of the lungs, as in singing, coughing, playing upon wind instruments. Like epistaxis, and indeed more frequently, it immediately originates from obstructed nostrils. Sometimes it appears vicarious of a gouty paroxysm.

M. M. "The faculty," says a modern author, "of repressing the primary symptoms of phthisie pulmonary, is proportioned to its difficulty of cure when the characters of the disorder are fully complicated, and the texture of the lungs not wholly destroyed." (Reid on Consumption.) In no case, perhaps, is neglect or early management of disease more pregnant with irreconcilable evil, than in the consumptive affections. Digitals properly and timely had recourse to is the "anxiet of hope." In families where this fatal disease (pulmonary consumption) is hereditary, the use of this remedy as a prophylactic, will, I have no doubt, save many lives that would otherwise have been cut short. (Dr. Currie.)" Digitals is a remedy in pulmonary consumption in its earlier periods, which nullifies the disease regulations, and with sufficient attention on the part of the individual, circumstances of regimen and diet, may be employed with a prospect of almost invariable relief. (Dr. Reil.) Other testimonies, equally decided, might be adduced in favour of this valuable remedy. Warm bathing. A regular temperature in the air that the person breathe. Warm clothing. Avoiding currents of air. Assiduously guarding against damp, and especially against cold in the feet, as by sitting with the feet on a stone floor, or in oil-cloth. Milk diet, of which Hoffmann elegantly says, "Qua perplexis phthisicis, myocardium Clavotis facillitatem, et animum, saluabat." Avoiding all spirituous liquors, and spiced or high-seasoned meats. Keeping the bowels gently open by manna, castor-oil, senna, &c. Uva ursi has recently been recommended by Dr. Leeuwenhoek, to be used as a very gentle and efficacious purgative. Dr. Leeuwenhoek, by purgatives, prefers the use of the root over the bark, of Uva ursi. It is allowed to be a very powerful reneging in the stomach, and is considered as a purge, by some of the most Laennecian and modern authors.

These are the remedies of the first stage, or, more properly speaking, the menacing symptoms of consumption. When the lungs have actually become ulcerated after gradual and protracted irritation, very little expectation of recovery can remain. Griffith's mixture, composed of steel, myrrh, and aloes. Digitals in larger doses, and combined with the above tonic. Uva ursi, and vitriolic acid. Digitals combined with calomel.

Change of climate. If a tendency to absorption from the surface of pulmonary ulcer could be induced greater than the disposition of it, we might have some prospect of curing it in a more easy manner. In order to produce this absorption, sailing so as to occasion sea-sickness has been had recourse to. Swinging, riding in a carriage, and other modes of occupying a degree of vertiginous affection, and consequent nausea, have likewise been recommended and practiced. In
MEDICINE.

It is true that the exact contrary is the fact, for the malady will be occasioned with most facility when the circulation is weak and irritable.

Vvhy the membrane of the nostrils, &c., should be the readiest to suffer more particularly, it is not to seem of an easy explanation; it is important, however, to recollect that what has been pointed out in an explicit manner by Dr. Beddoes, and since by Dr. Reid, that this membrane is a part of the same expansion with that which lines the windpipe and enters the lungs; so that in fact a common inflammatory cold is a degree of the same disease with an inflammation of the lungs.

M.M. Moderate and equal temperature.

The bowels to be kept gently open. If the phlegmatic irritation is considerable, subtorics, Animorials, &c., are to be given. Oil or other substances may be used to lay the cough, but irritating balsams, such as cough medicines are generally composed of, are in the highest degree detrimental; they too often increase the disposition to, and sometimes actually produce, confirmed consumption. Liquorice, honey, boiled fig, almond emulsion.

If the phthisical tendency is conspicuous, digitals (see the section on Phthisis pulmonalis).

Genus II. Dysentery, dysenteria.

Symptoms. Frequent stools, mixed with mucus, and sometimes with blood, attended with griping and tenesmus, the proper definite remedy being opium, either sulphureous, or pyrexia, pulse quick and feeble. The disease is sometimes contagious and epidemic.

Causes. Dysentery depends upon the irritability of weakness, determined by particular circumstances to the alimentary canal; its predisposing and exciting causes are alternations of heat and cold, more especially when accompanied by damp, as when an army is encamped on marshy ground; the putrid miasma arising from the marshes; the contaminated effluvia proceeding from the discharge in the disease; and, according to Sir John Pringle, from dead bodies left unburied in the field of battle.

The immediate cause of the symptoms seems to be, a spasmodic constriction of the larger intestines, retaining the feces.

M.M. Colonel, opium, and rhubarb, to relieve the spasm, and discharge the contents of the bowels; magnesium acetate, as of starch with tincture of opium. Emetics. Small doses frequently repeated of peruvian. Colombo. Turpina bark. Warm bathing.

Class II. Neuroses, Nervous diseases.

Men is indebted for all his acquisitions to casual observation, leading to experiment. That the faculty we call the sentient resides in, or was developed through, the instrumentality of a peculiar and distinct organization, we should not, a priori, have conceived; there is nothing in the composition either of brain or nerve to lead to this conjecture. If, however, a portion of the bony defence of the conception be accidentally pressed in upon its substance, and an obstruction in the faculties of sensation and voluntary motion be the consequence; if such accident be repeated with the same result; finally, if it be found, as it has been, that by voluntarily producing pressure on this organ, similar effects may be occasioned in proportion to the degree and extent of the force employed; the impor-
ence will come at length to be indispensible, that the brain is the organ or reservoir of sensation, and that a lesion in the medium through which locomotion is effected.

Again, if it be found that at pleasure we can deprive any portion of the body both of sense and motion, by dividing the nerve supplying said part, or cutting off its common trunk with the brain, we are like to be fully justified in inferring, that the chord we have severed was the instrument by which the empire of the will had been exercised over the actions of the body of the brain itself, or at least the nerve supplying the organ in question.

This mode of inferring the nature of what is not an object of our senses, by comparing it with what can actually be observed, will be found equally satisfactory, in relation to partial as to total interruptions of sense and motion; thus, by a less degree of injury done to a nerve, as by lacerating or puncturing, instead of severing it, we shall perceive not an entire deprivation of, but merely an impediment to, the loco-motive faculty; the actions of the member will be in a manner refractory; and convulsive or irregular, instead of orderly and steady motion, will follow the mandates of the will. If then, without the interference of an experimenter, and without visible injury to the animal structure, the movements of an organ become improperly accelerated, or cease to be exercised in their usual mode; if, to instance by example, the heart perform two, or three, or four, or five, or six, or seven, instead of twelve, to twelve, to twelve, in the course of a minute, we conclude that the body is in an uneasiness which Hartley concedes to depend upon vibrations and vibrations, whether we embrace the doctrine of universally pervading ether, or subscribe to the tenable positions of the author of Zoonomia. Depressed perception and interrupted motion, are therefore the essences of nervous disease: the percipient, however, is to be distinguished from the motive faculty; for we have a class of living actions, which, although equally under the influence of nervous power with those over which the will presides, are nevertheless, in a state of health, incessantly carried on without perception or consciousness; thus, by impeding the functions of the nerves of the stomach, we may interrupt the function of digestion. Digestion, however, is a process performed without design, and independently of volition; on the other hand, it is necessary that it should be impeded by a derangement in the nervous system, while the digestive power shall proceed without the least impediment.

Dr. Cullen's definition of a nervous disease, would therefore have been more accurate, had he added an infection of either sense or motion, without idiopathic pyrexia, or visible disease of parts. The orders of this class (neuroses) are four:

1. Conatus. A diminution of voluntary motion, with sleep or impaired sense.
2. An insufficiency of the involuntary motions of either natural or vital functions.
3. Spasms, morbid motions of muscular fibers.
4. Vesane, disorders of the judgment or intellect without pyrexia, or observable affection of any particular part of the body.

ORDER I. Conatus.

Genus I. Apoplexia. apoplexy.
Symptoms. Abolition of the sentient and loco-motive faculties, the sleep in general attended with snoring. The respiration, motion of the heart, and other involuntary actions, remaining.

Causes. We conclude from the anatomy above-stated, that there is some degree of the pressure on the brain, or the apoplectic stupor; but that effusion of blood takes place in the manner described by the generality of authors, is exceedingly problematical; if the appearances on dissection are appealed to in behalf of this theory, it is answered, that such appearances can alone apply to fatal cases of the disease; and in such, an actual rupture of veins and effusion of blood will readily be admitted.

Epilepsia, palsy, and apoplexy, were confounded by Brown to originate from the mere irregularity of nervous power consequent upon debility or deficient excitement; and to be occasioned without either an unusual impetus of circulation to the vessels of the brain, or impeded return of blood from this organ. We believe, however, that although the cause of apoplectic often is in one sense mere deficiency of excitement directed to the action of circulation, the immediate occasion of the apoplectic symptoms is for the most part the state of the vessels of the brain.

Apoplexy, for the sake of illustration, may be divided into static and asthenic. If a vigorous and phletoric man, sitting down to his dinner and his glass, suddenly, during the excitement of conviviality, of mirth, and of alcohol, fall on the floor with deprivation of sense and apoplectic seizure, it must be evident that the fit has been induced by a greater flow of arterial blood into the vessels of the brain, than the veins of this organ could, in due time, convey away. The apoplexy has been induced in the manner of a silene disease.

If, in the other hand, a debauched and debilitated individual be the subject of an apoplectic attack, at the time when the excitement of intoxication shall have been succeed by the condition of indirect debility, the disease will here have been brought about in a different manner; the impetus in the vessels of the brain shall have partaken of the general diminution of power throughout the whole system; sluggish vascular action shall have caused congestion; which congestion, in union with the deficient excitation on which it had depended, shall have induced that sudden suspension of the sentient faculty which constitutes the apoplectic paroxysm.

Apoplexy often immediately succeeds to a full meal: what more natural than, under such circumstances, to attribute the fit to a distended stomach pressing upon the aorta or large descending blood-vessel, and consequent expanse or dilatation of the heart, and increase in the imordinate measure to the head? Such conclusion, however, will not bear the scrutiny of strict enquiry. Upon this principle, the apoplectic stercor and incommensurability ought to be induced within the cranium, and not in one dysy or night-mare, while the body is in a recurrent posture, and the stomach is most distended from the extrication of gas which takes place in consequence of the weakened digestive power; in place of this, however, the fall is immediate; the attack is made while the body is in an erect position, and often before the stomach has become in a very great degree distended; the fit then arises, in this last case, from an insufficiency of the digestive powers they have called off to their aid, leaving the brain in a condition of insufficient energy, properly to propel the vital fluid through its own vessels; congestion will result, and this last will produce the apoplectic or immediate cause of the fit.

M. M. The strictest attention to the manner in which the disorder has been brought on. If the disease is ethicus, and the physicals are called while the paroxysm still continues, immediate and copious bleeding from the arm, the jugular veins, or the temporal artery. Every ligature about the patient's body, especially about the neck, to be loosed immediately. Press hard with the thumb and fore-finger upon the carotid arteries, taking care to avoid the jugular veins. Place the head of the patient high on his pillow, or seat him erect in a chair. Preserve the apartment cool. Cold water may in some cases be applied vigorously to the forehead and temples. Afterwards saline purges, and subacid drinks. Encem. Careful preservation from irregular and violent excitations, either of body or mind. In theէ harvest form of the complaint, bleeding with much less freedom and only during the paroxysm; in general, it is not at all proper. It is better to open the temporal artery, if convenient, than to allow the complaint to continue. The application of cupping-glasses is still preferable; apply blisters to the neck. When the power of deglutition has returned, cordials and stimulants. Opium and wine in very small doses. Volatile alkali. Sprinkle vinegar about the room. To prevent the returns of the fits; tonics, particularly bit ter, as colocombo, gentian, quassia; exercise and mental amusement, without violent excitation. Journeys to Bath or elsewhere. Preserve the body regularly open, without violent purgations. Avoid sudden exposure to cold, especially cold and wet feet. If the fit has followed the suppression of any accustomed discharge, or cutaneous eruption, let them, if possible, be restored.

Genus II. Paralysis, palsy.
Partial interruption of the loco-motive faculty, sometimes with a degree of apoplectic stercor.

This is partial apoplexy, arising from similar causes operating in a less degree. It
MEDICINE.

Cuonik daces to a full fit of apoplexy, and continues for some time during life. The pulse often affects the whole body, and is confined to that side; hence it has been supposed, that the injury of the brain is likewise partial; and from the degeneration that has been in the brain from the encephal, Dr. Darwin and others have concluded, that the origin of the disease is on the side of the brain opposite to the affected side.

Palsy, however, certainly originates at times (even if genuine apoplexy does not) from interrupted excitement, without any congestion in the brain, as its more immediate source, as it results from the poison of lead and other poisons.

M. M. Ascertain the exciting cause, and, if possible, counteract it. Emetics, purgatives, preceding stimulants and tonics. Tonic and stimulants, and whilst in the paralyzing state of life, and have been many remedies. This is said to be the case when the loco-motor power, and the energy of the muscular fibre, shall have been restored to their former state. In such cases the recovery is rapid, and the past, and anticipation of the future, have both probably been irrecoverably lost.

The more possibility of his being reduced to this condition of humiliating existence, one would think a motive sufficiently powerful to check the imponderable in his course.

Order II. Agyria. Secyno. Stump, fainting. Syphon, spasm of constriction, or even, for a time, a total cessation, in the action of the heart.

Fainting may arise from passions of the mind; from sudden reduction of stimulus, either from loss of blood in the region of the heart; from perspiration; from the irritation of worms, or other poisons, in the stomach and bowels; much heat, offensive ejecta, &c.; in these cases the disorder has been called syncope cerebral. When fainting arises from deficiency of oxygen in the circulating air, as in a crowded assembly, the cessation of the heart is produced nearly upon the same principles as in actual suffocation, drowning, or hanging. It is termed syncope pulmonae.

M. M. Immediately obtinate, if possible, the exciting cause. Endeavour to restore sensation by aspersing cold water on the face and neck; attempt to clear down a small quantity of blood; and in cases, but more especially when the affection arises from impure air, throw open the windows, and prevent compassionate spectators from crowding to the scene of action.

N. B. If fainting, or palpitation, recur frequently, and without any manifest cause, perhaps as a prodromus or exciting, there will be reason to suspect that the disorder is not nervous, but depends upon some malformation in the heart, or neighbouring blood-vessels. In this last case it is irremediable.

Genus II. Dysepsia, indigestion. Symptoms. Hypochondriac pain, indigestion,-nausea; vomiting; inflammation from flatulence; heartburn; pain in the stomach, especially when the body is in a hot position; nervouss breathing; costiveness.

This disease evidently arises from deficient action in the muscular fibres of the stomach, which in violent cases amounts to inverted motion and vomiting. It acknowledges the same sources as other affections of weakness; these are, inter alia, various liquors, and of tea; exposure to damp and cold; irregular hours of repose; intense study; mental depression and anxiety; when originating from this last source the disorder has an equal claim to the appellation of hypochondriasis, or low spirits, with that of dyspepsia.

M. M. Purgatives, with calomel, previous to giving tonics. An emetic. Coluchsia, gentian, quassia, &c.; in diagnosis, in order to neutralize the acidity, and case the consequent pain of heartburn.

Chalk, which is used with the same induction, is improper, on account of that neutral compound which it forms with the acid of the stomach becoming insalubrious, and more and more tending to increase the digestive state. The dyspeptic must be persuaded that a horse is a better physician; and that temperance of every kind, with reasonable disposition and exercise in a dry healthy air, will do more for him than all the medicines in the world. (Townsend.) Cold, or shower, bath, in very warm, and warm bathing in cold weather. A glass of warm water after dinner, and supper.

Genus III. Hypochondrisis, low spirits. Indigestion, with languor, and causes apprehension of evil, more especially as it relates to the patient's state of health.

This disease and dyspepsia only deserve to be distinguished by separate names, inasmuch as the mental depression in hypochondria appears especially to increase the disease by which it is, in part, constituted; and such disease is again supposed to be beyond measure by the morbid imagination of the invalid. Thus, in some cases of confirmed hypochondriasis, the dyspeptic sensations shall be attributed to the sufferer by the immediate agency of a medical impostor.

M. M. Aim at converting soliloquy and apprehension into confidence and hope; not by deriding the feelings of the hypochondriac, and treating them as fanciful, but by breaking the chain of excited associations. Procure a gradual change of scene and of habits. Journeys to Bath, or elsewhere, according to the previous disposition of the patient. Bath waters. Warm bathing. Preserve carefully the alimentary canal free from colitures and viscerities by drastic purges and calomel. Maintain a regular moisture of the skin, without copious perspirations. Tonics with aromatics. Dr. Darwin particularly insists, and with justice, on the advantage of uniformity in the hours of meals: this uniformity should be extended even to medicinals, the same hour of repetition being invariably observed. "Sic et si dormit."

Genus IV. Colic, or green-sickness. Dysepsia; paleness of the skin and of the lips; lassitude; difficult breathing, and palpitation of the heart, after using more exercisers than usual, especially in going rapidly up stairs; pulse small, feeble, and sometimes very quick; coldness of the extremities; appetite deficient, and oftentimes deprived; pain in the back and limbs; coldness of the extremities; emaciated ankles, especially towards morning; and obstructed menstruation. "Chloros haurit debilis pulsa totum corpus, laxo utas et frigent omnibus." (Van Swieten.)

Dr. Cullen has, with much impropriety, classed this among the nervous diseases; it ought to have been transferred to the next contumacious division of disease, or rather regarded as an affection of the lymphatic absorber system. In cases of much debility, especially of disposition to torpor, in the absorbing and secreting vessels; if, at the time when nature demands a new secretion and discharge from the system, in place of generative living, due exercise, moderate and pleasant excitation of the mind, the ever-springs hope of youth, &c. be substituted to poverty and unforesomeness of diet, water and vegetable food; and verbosity, concealed, unproperly, and unreservedly, in the hours of pleasure; the effect is the disease now under notice: which, however, from much natural debility, independently of either mental depression, or physical actions, or any other cause, may be, and very often is, occasioned. Chlorosis, indeed, is of exceedingly frequent occurrence.

The immediate cause is evidently an inactive state of those vessels, more especially of such which supply the lungs, with the deficiency of red blood in the vessels, want of propelling power in the heart and arteries: hence want of menstruation, emaciated swellings of the feet, "patient et frigent omnibus."

M. M. Almost as certainly as some kinds of pain yield to opium, does even obstinate chlorosis fall before the power of steel. "Dum hoc utilius, inquit orbe, melius major calor." To steel, then, must the physician have just, and trust in every case of genuine green-sickness. It is necessary, however, frequently to commence with an acute; and in almost all cases it is perhaps best to give a purgative, joined with calomel, before the use of steel. Tonic bitters. Aromatics. Moderate exercise in a pure atmosphere. Flesh and milk. A bath of about eighty degrees, as Buxton, not by any means colder. Marriage.

Order III. Spasmis, Spasms.

In the introduction to the class Neuroses, we endeavoured to describe briefly the manner in which a knowledge was acquired of the separate functions and distinct diseases of the nervous system. In the case of spasmodic affections this is especially illustrated. If in any animal the nerves supplying a limb be denuded, and a violent stimulus be applied to its surface, the whole member shall be immediately thrown into convulsive agitation; a fact which is perhaps too often demonstrated in the same and other experiments. When then such convulsions movements appear, without experiment, and sometimes without apparent cause, a similar change is justly inferred to take place in the nerve or nerves passing to the organ which, may be the subject of the disease. There's one circumstance with respect to spasms, that,
MEDICINE.

both in theory and practice, ought always to be retained in the memory; this is, that the spasmodic or convulsive state of parts invariably implies debility. To act irregularly, is in all instances to act with deficient vigour; for the total destruction of these disorderly movements, performed in a given time, will not amount to the quantum of power displayed in the same time by healthy and steady action. This fact appears to be a sufficient refutation of Mr. Darwin's hypothesis, that convulsions are voluntary exertions of the muscles to relieve pain, even if we concede to this author, that the strict definition of volition ought to be the active state of the sensorial faculty in producing motion; in consequence of desire or aversion, whether we have the power of restraining that action or not; for, according to this principle, convulsion should be an actual and positive increase of vigour, which it is not; for while the utmost agitation is carrying on in the convulsed member or organ, if a due quantity of stimulus be thrown in, excitement will immediately follow, and in consequence of this excitement, false difference and firmness; in the same manner, but upon a different principle, as tightening the sail of a ship arrests its vibratory motions, but increases its actual and integral force.

If it appear difficult to conceive why a stimulant or exciting agent should produce this debilitated action, we must refer to the invariable law of existing excitation, that carried beyond a certain point, is immediately productive of indirect debility; thus when the galvanist convulses the leg of a horse, he throws in more of stimulus than is adapted to the fibrous excitability of the organ in question; he exhausts the irritability of the part; and the convulsion that follows is the consequence of such exhaustion, exactly upon the same principle that half a pint of wine shall give steadiness to the tongue, and firmness to the step, while a quart of this stimulus, taken in the same time, shall produce a temporary paralysis of the limbs, and render the speech softening and inarticulate.

We have indiscriminately employed in the above observations, the terms spasm and convulsion. As it relates to the excitement, they are virtually the same states; and thus, whatever convulsion is a spasm, that is, whatever rigid unmovable contraction, or rapid alternations of contraction and relaxation, follow the debilitated causes upon which they depend, in one sense they are scarcely to be distinguished; the difference of physiognomy, which they assume appears to have dependance upon the complicated associations of living actions, which are but little understood, and both in theory and practice too much disregarded.

From the above remarks we hope it has been rendered evident, that in attempting to overcome a spasm or convulsion, the leading principle of cure must be stimulative; the disease in question, however originating, invariably requiring dignity, or tender propery; perhaps, deficiency of excitement.

Sect. I. Spasmodic affections in the animal functions.

Genus I. Tetanus. A spasmodic rigidity of a great part of the body; in some instances it is drawn violently backward, at others forwards, and in both cases the disease is generally followed or attended by trismus or lock-jaw; these symptoms may last with greater or inferior violence from twenty-four hours to a month or more.

The immediately exciting causes of tetanus are, either prick or pressure of the hand, the sudden application of cold after extreme heat; great intertemporance, or other vices: the disease may likewise be consequent upon viaciar muff, worms, and other irritating substances, in the alimentary passages.

M. M. Purges, followed by tonics; mercury combined with opium.

Genus V. Epilepsia, epilepsy. Violent convulsions of the muscles, attacked with sleep.

Epilepsy in its nature and causes appears to hold a kind of intermediate situation between apoplexy and convulsion; it has the same duration as the spasm of the one, with the irregular muscular action of the other. Epilepsy, in a greater or less degree, is a disease of extreme frequency: indeed, all the convulsions of children may be called epileptic. In its full and formidable shape, it is not so frequently met with as several other diseases. A physician, however, may denominate, with propriety, all fits epileptic, of which alternate or combined convulsions and sleep constitute the characters, especially if these are connected with the increased action of the salivary glands.

M. M. Epileptic fits are sometimes congenital, hereditary, and depend upon some occult state of the nervous system. In these cases, the disorder is generally irremediable. All those that can be directly or indirectly ascertained, and endued, if possible, to obviate the exciting causes of the disease; and during the paroxysm to lessen every kind of danger to the head and head, preserve the aperture in which the fall is made as airy as possible, and be careful that the patient do not inflict injury upon himself by the violence of his agitation. In some cases, indeed, the individual can obviate the full formation of the paroxysm by laying a ligature round the limbs in which the sensation threatening the attack is perceived, between the point at which such sensation commences and the brain. This sensation constitutes what is called the epileptic aura; its abstract cause is obscure; but no less so than the phenomena of spasm in general.

In treating the complaint, particular attention is to be given to the predisposing and exciting cause or causes, which are extremely liable to this such irrepressible, indulgence in secret vices, mental passions and affections, imitation of other epileptics, lively recollections of previous impressions, repelled eruptions or discharges, sudden alterations of the extremes of temperature, unpleasant odours, and, as by far the most common source of those epileptic fits which scarcely amount to absolute epilepsy, worms. These causes must all necessarily be removed before the physician can have the least prospect of overcoming the disease. Emetics, cathartics with colonel; antiepileptics; suddenly discover the chain of associations, by plunging the patient in the cold bath, or delivering with violence cold water into the body. Induce a new disease, as the itch; a plan which Dr. Darwin adopted with success in the treatment of St. Vitus's dance, with which the present has a great affinity. Patients have likewise been cured of epilepsy by the accidental occurrence of a quartan ague. These are instructive cases to the reflecting and speculative. Tonics. Galvanism. By this newly discovered source of nervous excitation, the writer of this article recollects to have wit
Medicine.

Genus II. As hina.

**Symptoms.** Difficult respiration returning at intervals, with a sense of tightness across the breast. Whizzing at the commencement, and scarce secretion of any cough but what is hard; towards the close of the paroxysm it however becomes more free, attended with a discharge of mucus.

These symptoms certainly arise from a spasmodic constriction of the bronchial tubes, "which may be produced by consent to the larynx and diaphragm."

The causes of asthma are numerous, while its predominance is often hereditary, and dependent upon a peculiar conformation and temperament; the actual disease may be excited by temperance; either in eating or drinking, violent exercise, mental agitation, eruptions or discharges abruptly or unreasonably expelled; the tunes of metallic poison, as of lead, &c.

**M.M.** Spasmodic asthma, when fully established, scarcely admits of a radical cure.

The paroxysms to be relieved by opium and ether; coffee; tonics in the intervals, principally of the class of bitters and aromatics.

Avoid distending the stomach inordinately. Emetics; emesis previous to the anticipated accession; gentle horse exercise; pure air; oxygen gas. If eruptions have been expelled, endeavour to restore them.

**Genus III. Pertussis,** hooping cough.

**Symptoms.** Convulsive strangulating cough, with noise inspiration and hooping, and sometimes attended with vomiting. It is contagious.

The precise nature, or, as physicians express themselves, the proximate cause of hooping cough, does not seem to have been accurately ascertained. It is, however, supposed to be "an inflammation of the membranes which line the air-vessels of the lungs, and that it only differs from pericardium superficialis in the circumstance of its being coughing out."

It has been observed to be a morbid irritative fever; we are inclined, however, to think that the infection principally operates upon the stomach; and that the inflammatory disorder of the mucous membrane is merely a consequence of the irritation, or erroneous treatment, of the complaint. It is not attended, in the first instance at least, with the symptoms of inflammatory irritation; and the vomiting, by which the violent fits are often relieved, proves that the stomach, in pertussis, is in a morbidly irritable state.

It deserves however to be remarked, that the membrane in question is very apt to parake of the preceding irritation, to become inflamed, and thus, like the inflammation after small-pox, and measles more especially, to lay the foundation of consumption of the lungs.

**M.M.** Antimonial emetics. Very small doses. Warm bathing. Above all, digitalis; in no disease, perhaps, is the power of this valuable medicine displayed more forcibly and evidently than in hooping cough. Its effects are generally almost instantaneous. After the violence of the paroxysm has been subdued, and even before, change of air. Cicuta (cnicum maculatum) has been much employed in this complaint.

**Sect. III. To the animal functions.**

**Symptoms.** Sudden eruption of watery fluid with or without heartburn; the fluid brought from the stomach sometimes transparent.

**M.M.** The author of the present article recently had an opportunity of witnessing in this disease the beneficial effects of the ingestion of tobacco-smoke by a person not previously accustomed to smoking; this man had taken tonics, antispasmodics, and atacks, without effect. "A gram of opium twice a day, soap, iron powder, a blister." (Darwin.)

**Genus II. Colica, colic.**

**Symptoms.** Permanent and excruciating pain in the belly, with a sensation as of twisting about the navel, constipation, and sometimes vomiting.

**Causes.** These symptoms evidently originate from spasmodic constriction in some part of the intestinal canal, which may be occasioned by various causes: such as indigestible food, the sudden application of cold; acid substances received into the stomach; poisons, especially lead; hence colic is a kind of epidemic disease among painters, attended with paroxysm of the arms, &c. It is likewise common in cold countries.

**M.M.** Opium. Cataractis, principally of cataris oil. Warm bathing. Anodyne clysters, Fomentations and blisters to the part. In obstinate cases of the painters' colic, Bath waters. Carefully obviate the exciting causes of the disease.

**Genus III. Cholera.**

**Symptoms.** Vomiting and purging of bilious matter, violent pains in the stomach and bowels, with great and violent perspiration.

Cholera is one of the diseases of the autumnal months; it is very often produced by the sudden succession of cold to unusually warm weather: it sometimes follows the taking of indigestible substances, as of much cold cucumber, especially at the period of the year above-mentioned, when the directly debilitating power of cold abruptly succeeds to the indirectly debilitating operation of heat, and the biliary secretion is more than ordinarily copious.

**M.M.** During the violence of the vomiting and purging, give water-gruel, and inject starch clysters, to each of which add a little of opium. After the disorder has in some measure subsided, restore due excitement by cordial and nourishing diet, with stomachic medicines. If febrile irritation is induced, the saline draught, composed of salted wormwood and lemon-juice.

**Genus IV. Diarrhea.**

**Symptoms.** Frequent stools, without primary pyrexia, and not induced by contagination.

A morbid action in the exertories of the intestines constitutes this disease; sometimes however, and frequently, purging arises...
MEDICINE.

from more loss of excrebin in the intesti-
nal fibres, without increase either of bile or
any other secretion. It is immediately oc-
casioned by acrid matter in the stomachs;
by acids, by mental passions, or by the
sudden application of cold, more especially
to the feet.

M. M. 3. According to the exciting causes.
If there is reason to suspect the lodgment of
acrid matter, cologne, with jepa, senna, or
rubarb. Afterwards astringents, of which
one of the best is good red wine. Opium.

Chick, if acridity prevails. An emetic if the
disease is obstinate.

Genus V. Diabetes. 

Symptoms. Superabundant discharge of
urine, in some cases amounting to fifty
pounds in twenty-four hours, limpid and
very close to the taste, with urgent and
perpetual thirst, dry skin, weakness, emaciation.

This disease often, perhaps, exists to a very
considerable extent without being detected.
It is not an uncommon complaint among the
poor, especially of the north of Brit-
ain.

The principal circumstances that have
attracted the notice of the pathologist in re-
ference to this complaint, are the saccharine
quality of the urine, its evacuating nature, and the
at-
tentive evacuation. One of the principal
ingredients in the nutrition of the body has
been supposed to be the saccharine principle;
from the inordinate discharge of this prin-
ciple in the diabetic urine, the disorder has
been therefore referred to some to a de-
ciency of assimilating power in the stomach
and digestive organs, while others have in-
ferred from it to originate entirely from alter-
cation in the kidneys. Perhaps both of
these causes may operate in producing dia-
betes. Upon dissection, the kidneys are al-
ways found lacerated. Dr. Darwin, after Mr.
Charles Darwin, attributes the copious flow of
urine to the inverted or retrograde action of
the urinary lymphatics; but besides that
thesis does not account for the super-
abundance of sugar or of mucilage in the
water, it has been proved that such inver-
sions are not always accompanied with their
structure and general economy.

M. M. 4. Animal diet. Dr. Rollo and
others have observed that when the patient
live on animal food, the saccharine quality of
diabetic urine abates. Alkaline and ac-
sthetic medicines, such as tart-galls and
limewater. Bark. Steel. Opium. Ament-
away. 

N. B. A copious flow of urine is fre-
cently observed to attend nervous affections, and
indeed is one of the characteristics of the
disease we are next to notice; in these cases
however, the water has not the superabun-
dance of the saccharine principle as in genu-
ine diabetics, which last disorder has been ex-
tremely placed in the class Neuroses.

Genus VI. Hysteria. The hysterical disease.

Symptoms. A gurgling of the bowels, fol-
lowed by gulsms hystericus, or a sensation
of a ball ascending to the throat, and mean-
ing suffocation. Convulsive agitations, al-
ternate laughing and crying, a general flac-
kuiness and languor of the body, followed
by extraordinary fatigues. A deficiency of
vitality of straw-coloured or limpid urine. Hys-
teria, like epilepsy, is in a certain degree
extremely common; it generally first occurs in
}females about the time of puberty. It is
like all other convulsive diseases, a symp-
tom of a lux habit, and is consequent upon
the irritation of the nervous system. It may be
brought on by mental agitation, or by irrita-
tions in the stomach, bowels, uterine or-
ines, &c.

The discharge of urine which attends or
precipitates hysteric presentation, is attributed by
Dr. Darwin to the inverted motions of the
lymphatics about the mouth of the bladder,
as in diabetes; a temporary torpor, or spasm
of these vessels, would appear sufficient to ac-
count for the superabundant excretion, the
watery part of the urine not being taken
up.

M. M. 5. Avoid every occasional and ex-
citing cause of the disease. Park, quassia, and
other tonics. To remove the present symp-
toms, camphor, asetatecd, caustor, opium; if this
does not succeed, the best and most effectual
is the patient, the hyposyamus will generally
be found an excellent substitute. This has
not the constipating tendency of opium; and
in hysteric cases it is of importance, while
it is easy to be obtained, to preserve a freedom
both in the alvine and cun-
nacular discharges. Emetics, N. B. The cus-
mary plan of bleeding in hysteric affec-
tions is extremely detrimental to the general
health, and especially to the return of the
rigorons. If it is judged necessary in some
cases of hysteria to withdraw a small quantity
of blood, it should be done not by ven-
section in the ordinary mode, but by the ap-
plication of a crotchet, which is thought to
be of some service.

Genus VII. Hydrophobia. 

A dread of water as exciting painful con-
vulsions of the pharynx, caused for the most
part by the bite of a mad dog, violent spasms,
violent irritation, death.

M. M. 6. "When the contagion of a pad-
tic fever is taken by the saliva into the stom-
bach and bowels, when the integuments are
quivered (quiver) at the patient the moment he finds
himself attacked with a sense of chilliness,
loss of appetite, and an unpleasant taste in
his mouth, has recourse to two emetics at
proper intervals, one of which is an emetic and
the other the inorganic. If the first emetic
takes a cathartic, he has certainly got rid of the infection in
the same manner, even after three days, or per-
haps a week, if the part bitten by the dog be
not cut off with the knife, the danger is escaped."
(Townsend.) Dr. Thornton advises the ap-
lication of hot vinegar, sharpened with vi-
ricose acid, to the wounds of five men who
had been bitten by a rabid animal, and the
application was attended with seeming suc-
cess. Mercury, by this has been ex-
tolled as a specific for hydrophobia.

Order IV. Vesania. 

Disorders of the intellect, independent of
pyrexia or convulsions.

Every nervous disease, (says a author
whom we have before quoted) is a degree of
insanity. But, however, imagination carried to
the height of sentiment perception, or, as
it has been expressed by Dr. Baty, the rais-
ing up in the mind of images not distinguish-
able from impressions on the senses, is the
proper definition of the insane state;* the
cardinal point on which madness turns, the
above apothegm of Dr. Reid may be
regarded as rather bold and impressive than
strictly accurate. It were surely improper to
demonstrate the apoplectic, the paralytic,
the hysterical, or the tetican, insane; yet an
individual under these maladies, is as truly
as any other disease considered as one who:
like the lunatic animal, consents to give
himself to possess the mastery of the ele-
ments, commands rain to shed fertility on the
barren soil.

That the disorders of the intellect are dis-
orders of the nerves, we ready admit; it is
the converse of the proposition we presume
to question; and in so doing, we justify Dr.
Cullen, in considering the vesania, or nex-
tal affections, as a distinct order of nervous
diseases.

The pathology of such diseases is peculiar-
ly perplexing. We find by experience, that
an increase of vascular action in a tender
organ will give rise to the feeling of pain,
we have ascertained by the conjunctive and
mutually reflexive aid of casual observation
and direct experiment, that convulsive
movements in the muscular fibre are occasioned
by an immense injection of nervous excitement in
whatever that may take the brain is exer-
pressed upon, and the apoplectic stupor fol-
low; but in endeavouring to trace deranged
consciousness to disordered organization,
temporary or permanent, an increase of in-
tracranial action and intensity of manner to grow out of
labour and research.

Dissection does not afford that assistance to
the pathologist in this, as in many other
departments of his inquiries; for indepen-
dently of the great want of uniformity that has
been observed in the brains of the unfortunate
victims to mental derangement, it is impos-
sible to judge from an inspection of this or-
organ, how in the altered structures and ap-
pearances have been causes, and how far
consequences, of the malady.

Dr. Cullen has four genera in his order vesania, viz. amania, melancholia, mania,
and oncoelia, on each of which we shall
introduce a few remarks.

Genus I. Phrenopsie, insanity.

Amenia is defined an inabibility of judg-
ment, preventing the proper reception of the re-
collection of the relations of things.

Man is born with merely a susceptibility
of knowledge, a capacity of acquisition; he
is educated from observation to comparison,
and from comparison to principle. Place an
infant in a spacious apartment, give him for
the first time the use of all the senses with
which nature has furnished him, and he
will stretch out his hand to perhaps the most
distant object in the room, with a full per-
ception of being able to grasp it. Like the
youth counselled by Chlodon on Epict. Down,
everything within the scope of his vision
appears to him in a manner to touch his eye,
he has not the smallest conception of the
distance or magnitude, and the same total
ignorance prevails in respect to objects
which have relation to all his other senses.

Insanity results from the experience of
something which may make a comparison of
the relations of things.

As man, however, essentially differs from
the brute, by the more extended compass of
his intellectual grasp, the superinduction
of a period, and the anticipation of future
events, so different individuals have varied
susceptibilities of acquiring informa-
MEDICINE.

151

tion; and this variation, which constitutes every shade of the different suicidal characters, must necessarily arise either from difference in the perceptive organs, or circumscription and retaining faculty. When then, without any apparent deficiency of the external senses, which are the inlets to knowledge, we find an individual not to have arrived at a given standard of intelligence by the constant employment of such senses, not to have obtained a due knowledge of "the relations of things," we place him out of the range of intelligent existence; have an obscure conception of something defective in the interior structure of his sentient organization, and denominate him an idiot.

This is the amentia congenita of Cullen, idiocy from birth.

Idiocy, however, may be produced. Facility may succeed to intellectual vigor, and the whole fabric of acquired knowledge be undermined and overthrown. Thus man may be reduced to the state of a second child. This state may be engendered abruptly and visibly, or gradually, and almost in an imperceptible manner. It may follow violent agitations of the mind, or be traced to a prolonged mental state, or may be brought about by the gradations of natural decay.

The causes of idiocy, when it is not the result of original malformation, are, all kinds of atrophy, more especially indulgence in the use of spirituous liquors: "it has been traced up to somnolence too much indulged." The media through which it is principally occasioned are mania, apoplexy, and above all epilepsy. When epilepsy is established even in youth, very little hope of recovery can be entertained by the friends of the unfortunate victim to his own impiety. The vindication of idiocy is a condition beyond the reach either of physical or moral influences!

Genus II. Melancholia.

Genus III. Mania.

We have placed these two genera of Dr. Cullen together, as we deem our author fundamentally erroneous in considering them distinct affections. Melancholia is "partial madness without dyspepsia." From this mode of reasoning, mania, instead of being distinguished by the character of universal madness, would have been with as much propriety designated partial madness without fever.

Insanity is intensity of idea, creating imagination into implicit belief, and thus producing an incongruity of action; incongruity is it respects former, consistency as it relates to present, improbability and associations. It partakes of the character of mania or melancholia, of violent rage or gloomy despondency, according to the previous temperament of the sufferer, and the nature of the prevailing idea. In each the disordered associations are engendered upon precisely the same principles.

Madness differs from idiocy, as the conclusions drawn from erroneous principles, in philosophy we differ from the conceptions of ignorance: the one proceeds from erroneous premises, the other is defective judgment from defective information.

How this intensity of idea is produced, we have no means of ascertaining: we do not indeed feel it difficult to comprehend, that an absorbing attachment to one object, or an exclusive attention to one particular pursuit, may come at last to make shipwreck of the understanding; but it is the susceptibility of being carried away by this idea, that constitutes the maniacal mania, the qu’un atome déplace, pour t’en faire périr, pour te dégrader, pour te ravir cette intelligence dont tu parais si fier! So precarious is the tenure, even of the most exalted possessions of man!

Madness, however, like idiocy, may be produced through the medium of bodily disorders; thus, fever will often occasion delirium, which is a species of temporary insanity. Thus, an obstruction of the menstral discharge will frequently be the cause of the development of disordered ideas, or maniacal disorder, occasioned by previous disease, resulting from erroneous education, or depending upon hereditary conformation. Indeed, almost the whole range of nervous diseases may, under predisposing circumstances, come to be excusable in cases of genuine insanity. When lunacy has been brought on by bodily disorder, the completion of the derangement shall be formed by the previous temperament, or the natural disposition of the sufferer; thus, the favourite ideas of health shall, in their increase, be the predominant and overwhelming ideas of madness; again, when the insane state has more immediately proceeded from passions of the mind, or moral rather than physical causes, the ideas that have vanquished the intellect shall continue to reign. The imaginary monarch shall preserve his dominions and sway, and through the medium of his distempered fancy, shall observe menials and attendants in the persons who surround him; the melancholy lover shall require but a female form to pass before his cell, to be persuaded of the actual presence of his affections; and the religious enthusiast shall read a special embassy from heaven, in the countenance of every compassionate visitor.

Prognosis. "The chances of recovery are against those madmen, who can trace their indisposition to lunatic ancestry. When the causes are accidental, or obviously corporeal, a favourable termination may be expected. "The insanity subsequent to parturition, is generally curable if the curative attempts be rational. (Cox.) "Patients who are in a furious state recover as eagerly proportion, than those who are depressed and melancholy. When the furious state is succeeded by melancholy, and after this shall have continued a short time the violent paroxysm returns, the hope for recovery is very slight. Indeed whenever these states of the diseased frequently change, such alteration may be considered as unfavourable. When insanity supervenes on epilepsy, or where the latter disease is induced by insanity, the case is very seldom effectual. (Halsted.) "When a person becomes insane who has a family of small children to solicit his attention, the prognosis is very unfavourable, as it shews the maniacal hallucination to be more powerful than those ideas that generally interest us the most." (Darwin.) "Though individuals of every temperament become insane, it has been observed that those of the singuine more frequently recover."}

M. J. Endeavour to draw off the mind from the prevailing idea, or to convince the maniac of the errors of his conceptions, and fallacy of his pretensions, by relating the incongruous conceits of other maniacs which have some affinity with his own. M. Pinel states, that in the Bicetre of Paris, a maniac was cur'd by a suggestion that he had been a party to the guillotine, and that mother of mother had been placed on his shoulders, by a person judiciously ridiculing in his hearing the miracle of St. Denis, who was said to carry his head under his arm, and to kiss it. When the maniac was endeavouring to prove the posibility of the fact by an appeal to his own case, the narrator of the story suddenly exclaimed, "Why, how, you could kiss your own head? was it with his head?" In inept and equivocal madness, cautiously abstain from expressing suspicions in the hearing of the patient. Nothing is more certain than the ideas of a person mad than the idea of being thought so. (Reid.) On this account, premature confinement is to be deprecated, not merely as cruel, but as injudicious in the extreme. Those who are placed in the lunatic asylum as guardians, should unite decision and firmness of character with tenderness of disposition and gentleness of manners.

In strong phlegmatic habits, venesection. Cathartics. These last, especially in melancholy, often require to be of the drastic kind, and united with calomel. "Distillation very often proves a natural cure of insanity." (Haslam.) Vomits. Camphor. Opium in large doses. Cold bathing during the violence of the paroxysms, and in some cases warm bathing in the intervals. During the urgency of phrenzy, apply cold water to the head. Clay exp. Bisters to the scalp. In some cases the production of a vertiginous state by rotatory movements has been found effectual in breaking the morbid associations constituting phrenic and melancholy paroxysms, Digitals in very large doses, but regulated with care. Introducing a new disease, which shall fascinate, sooth, and easy of cure. "I should place considerable hopes on inoculation, had the party not previously had the small-pox, taking care, by proper medicines and management, to increase the symptoms that usually attend this last disease" to such a degree, that the whole system be considerably affected without the life being endangered. (Cox.)

In instances where madness has originated from corporeal diseases, it scarcely requires to be observed, that a considerable part of the treatment must be constituted by the administration of those remedies that in common cases of these affections have been found to be effectual.

Genus IV. Oneirodynia. This genus is described by Dr. Cullen as a violent and distressing imagination in time of sleep." It is divided into two species: the active, or that exciting to walking and various other motions; and the grasp, with sense of weight or pressure on the chest. This last is the
MEDICINE.

habit of authors, or nightmare, which is constantly placed erroneously among the disorders of the judgment.

The former of these is generally either congenital, induced by unknown causes; it is perhaps primary, and strengthens the almost unlimited power of one sense, when concentrated as it were, or employed to the exclusion of the rest. Dr. Darwin relates the case of a gentleman who had lost his sight, entering his room, and immediately inquiring of him the length, breadth, and height of the apartment, by the undivided exercise of his sense of hearing; an accuracy which he could not have arrived at, had he retained the faculty of sight. In like manner the sleepwalker "will unlock his door, wanderer from home, avoid opposing obstacles, and pass with safety over narrow bridges," which during his waking hours he would have deemed as unable to accomplish.

The incubus, or night-mare, appears to arise from an interruption of the circulation of blood through the lungs, from defective irritability in those organs, induced by fatigue, or worse, "a full supper and wine," which last, in some persons, will almost invariably induce the disease.

M. M. Temperance; especially moderate suppers. "To sleep on a hard bed with the head raised." Enemias of loch and colon. Tonics. Sleeping in a literary apartment, and without curtains to the bed.

Class III. Cachexia. Cachexies. Previously to an acquaintance with the distinct structure and separate functions of the nervous system, before the important discovery of the circulation of the blood, and more recent, but hardly less important, development of the anatomy and physiology of the secreting and absorbent vessels, the notions of pathologists on the mode in which disease, local and general, is occasioned, were indistinct and erroneous.

When, for example, on the surface of the body appeared a peculiar eruption, which after a certain time broke through the outer skin, and discharged an offensive matter, it was natural to infer that such discharge was expressed from a deprived condition of the solids or fluids of a diseased system in the same manner as exhalations proceed from dead and putrid animal or vegetable substance, or as water is formed in the fermenting vat. Hence, the use of the terms had habit of body, foulness of blood, pecuniary of humour, cachexies.

These gross and indiscriminate opinions respecting the actual nature and immediate cause of disease, are now retained alone by the vulgar; and as the separate functions should keep pace with the advances of science, the word cachexy, as descriptive of those affections we are now to notice, ought to be banished from the phraseology of the nosologist, and a generic title substituted, indicative of disordered or deranged action in the secreting, absorbing, and glandular organs.

Order I. Marcores. A wasting of the body or general emaciation.

Genus I. Tubes. Asthenia, emaciation, and hectic.

Genus II. Atrophia. Asthenia, and emaciation without hectic.

Dr. Cullen has properly distinguished the emaciation connected with hectic fever, from that independent of this as a primary and essential character. The latter, however, or atrophia, should not appear in the last class of diseases. When, for example, in consequence of mental affections, of engorgement of the brain, of the fluids, of deficiency in the quantity or depravation in the quality of the diet, a loss of flesh and strength is perceived, the effect shall have been occasioned without any loss in the absorbent vessels; and consequently without hectic; for let it be retained in the recollection, as a principle of the utmost importance in practice, that where hectic fever is present, a greater or less degree of derangement in the lymphatic vessels is likewise present. Hectic fever is a disease of the absorbent system.

For the purpose of illustrating this distinction between tabid and atrophic disorders, let two individuals be supposed equally emaciated and equally weak; but this weakness and emaciation in one shall have been induced by an indisposition to take a due quantity of nourishment, in order to supply the losses which the body has been in a state of continues, by the loss of bulk and of strength, an equal, or even greater quantity of aliment shall have been received into the stomach. Now, in this latter case, the tabid state has been occasioned by a moral condition or improper action of those vessels whose office it is to separate the nutritive part of the food, and convey it, properly prepared, to the blood-vessels (see the article Dr. Cullen); the other has proceeded from a want of those materials upon which these vessels exercise their functions. In the one the hectic flux from the very onset of the malady shall imprint the check; in the other, hectic will not be occasioned until the absorbents, from not being properly exercised, come at length to be disordered. The one complaint is the tubes of Dr. Cullen; the other is the atrophia of the stomach; the one is consumptive, the other atrophic.

We have been particular in pointing out this distinction, because it is not sufficiently noticed by writers in general, notwithstanding its extreme importance in practice; and because, by keeping it distinctly in view it shall be enabled to reconcile the apparently contrary operation of those medicines which are employed with varied effect under different circumstances of debility and emaciation.

Steel, for instance, is one of those articles which on account of their almost magic power over so many diseases of debility, have been indiscriminately recommended in all; it has acquired this repute in the hands of a tonic medicine, but as a tonic it often fails.

Now let us trace its effects in the two species of emaciation just alluded to. In the first stage of atrophy its administration will be often followed by irritable action, in the place of due excitement; the attendant febrile heat (not hectic fever) will be augmented, costiveness and an acid skin will follow, and indeed all the symptoms of the malady be heightened.

In tabid diseases, on the other hand, the reverse effects will arise. Here the fever is hectic; and in the same degree that this valuable medicine, when duly employed, had increased the febrile irritation in atrophia, it will assuage the fever of tabs, and from the same cause, the stimulus which it imparts to the absorbent and hectic state.

How hectic fever originates, it is difficult to explain: its symptoms have been attributed by a writer of the present day to that surplus of excitement being expanded upon the arterial, which is supported by the deficient excitability of the absorbent system. This, however, is rather a statement than an explanation of its essence. The characteristics of hectic are principally the circumscribed redness on the cheek appearing more evidently once or twice in the course of the day, usually after meals, and alternating with a more than ordinary paleness of countenance; the pulse is feeble and quick; like the crimson flush of the cheek, it is accelerated by any thing received into the stomach; the urine is for the most part high-coloured, but deposits a bran-like sediment after standing for some time; the tongue is not furred in the same manner as in fever in general, but is clean; and often, as the disease advances, it increases in redness, the exact contrary to what is observed in genuine fever; the sweat is partial and irregular, and not attended with the same degree of temporary relief as in other cases; and in the advanced periods of the complaint, principally breaks out about the neck, breast, and shoulders; as the disease proceeds, debility and emaciation succeed, the legs and feet become atrophied, and (particularly) the skin (though the fatal close of the malady on which the hectic depends) delirium at length supervenes.

M. M. In atrophia, a supply of nourishment, equivalent to the loss that may have been sustained; if emaciation has arisen from mental disturbance, the remedies must chiefly be made to apply to the mind. Tonics from the vegetable class, such as colocynth, quassia, and gentian; not steel. Minute the febrile irritation, by keeping the bowels gently open by the milder purgatives, such as rhova, senna, and castor oil. Preserve a slight moisture of the skin by small doses of animalia, i.e. calomel, sugar of lead, not violent or agitating, exercise. Shower-bath in very warm, tepid bathing in cold weather. Pure air.

M. M. or emaciation, accompanied by primary hectic. An exercise that may accomplish the double purpose of forcibly expelling vitreous and intestinal acidity, and exciting the languid absorbents. Draught purgatives, as jalap or aloes, with calomel, with the same intention. Steel, in conjunction with Peruvian bark or biters. Force exercise. Warm bathing.

N. B. Tabs is for the most part symptomatic of other complaints, as of a disease of the lungs or the liver; and in such cases the remedy by which it is to be overcome is the treatment of the original or radical malady.

Order II. Intemaeceutia, general swellings.

Sec. I. Adipsos, Fatty swellings.

Genus I. Palynsecelia, obesity. This arises from the deposition of oil in the adipose membrane—becoming distended by the exhalations of the body. It proceeds in general, from indolence and intemperance.
Genus I. Pneumonial, a tense elastic swelling of the abdomen, tense, elastic, painful, and attended by costiveness.

Pneumonial, or the breaking of the cellular membrane from air; it may arise without any evident cause, and in this case is denominated by Dr. Cullen the spontaneous or the distending phalanx, which may be introduced by means of an external wound, as of the thorax, in compound fracture of the ribs: sometimes elastic swellings of the whole body follow, from the application of poison; and at others, pneumonial appears as an attendant upon the hysterical disorder.

The pathology of this disease, unless when it arises from wounds, is exceedingly obscure.

M. M. Scarifications, compresses, tonics.

Genus II. Tympanites, a windy swelling of the abdomen, tense, elastic, and painful, attended by costiveness.

Tympanites, swellings, both of the intestinal canal and of the cavity of the abdomen, often take place in conjunction with anaesthesia, or other disorders of debility, and frequently arise from sedentary habits, hypochondriacal affinities, or morbid symptoms. Tympanites are sometimes connected with obstructed menstruation, and in this case is seldom overcome but with the return of the menses.

Genus III. Physometra, an elastic swelling in the hypogastrium, consequent upon fluctuating distension of the womb.

It has frequently occurred in the female with the hope of pregnancy, till nature explains the mystery, and her expectations vanish in air.

Sect. III. Aqueous, watery swellings.

Droplexial enlargement is distinguished from pneumonial by its being inelastic, or pitting from the pressure of the finger, and slowly recovering its former form.

While considerable obscurity attends the nature and probable cause of windy swellings, the theory of droplexial affection is sufficiently evident. Droplexia is a collection of serous fluid, either in the cellular membrane, or in the cavities of the body. It is invariably occasioned by exhalation being disproportionate to absorption; this increase of exhalation and diminution of absorption results from debility, which may be either direct or indirect; the latter follows increased action of the vessels, as in the dropsy succeeding to intemperance; the former arises out of deficient excitement in the lymphatic system, as when an individual becomes droplexial from incontinence, inactivity, mental depression, and poverty of diet. Partial droplexes, or anaesthesial swellings of the cellular membrane, as well as effusions into cavities, may also originate from pressure on the veins in dependently of original debility in the lymphatic vessels, such pressure obstructing the free reflux of blood through the venous system, and occasioning occasional a more than ordinary determination to the exhalant arteries in the vicinity. Such are the droplexial accumulations which sometimes occur in pregnancy, and which are relieved by delivery. In this manner likewise, that swelling of the abdomen, constituting ascites, partly originates when it is caused or attended by an obstructed circulation through the liver, the blood in the venae portae accumulating in an inordinate measure, and by consequence supplying the lymphatic vessels of the part with more than their due proportion of fluid. Lastly, we have the intestinal and debility in the exhalant and absorbent vessels, droplexial swellings may arise from inflammation, as is illustrated in the anaesthesial collections following eczema, in the diphteritic swellings on the neck, in the dropsy of the chest resulting from inflammation of the lungs, and in ascites following peritonitis inflammation.

In whatever mode, and to whatever extent, dropsy may be occasioned, the accumulation of serous fluid by which it is constituted, always argues debility in the lymphatic vessels of the part in which this accumulation occurs. This debility, perhaps, is primarily and principally sedent in the lymphatic exhalants; for we do not find hectic fever a characteristic of hydrops, as it is of other affections, in which an original torpor of the cellular texture is evidenced by the most evident symptoms. Hectic only comes on in the last stages of dropsy, when the absorbents are worn out with constant exertion to absorb the effused fluid.

We have hitherto spoken indiscriminately of droplexy of cavities, and of dropsy in the cellular membrane; these, however, although they often exist conjointly, require to be distinguished; for instance, an accumulation of water in the thorax, may be confined to the cellular texture of these organs, and form the disease properly distinguished by the designation of anaesthesial pulmonum; or it may be diffused in the cavity of the chest, and constitute the true hydrops pectoris, or hydrothorax. The former generally arises from an universal torpor of the lymphatic system, and is almost constantly connected with hydrops swellings of other parts, particularly the ankles and legs; the latter often originates as a local disease, as from an inflammation of the pleura, and is sometimes confined entirely to the chest.

Dropsy is the cellular membrane immediately under the skin appears principally in the lower extremities, on account of the dependent situation of these members, and the universal connection between the cells of which the membrane is constituted; and partly on account of the deficiency in lymphatic excitement, from which it originates, being more conspicuous in those vessels which are the furthest removed from the centre of the circulation. Anaesthesial, as it arises from exhausted excitability in the lymphatic vessels, is always a disorder indicating much danger.

M. M. Digitalis, in considerable doses, are especially indicated in droplexy of the chest, and its effects are more visible as well as more certain in the anaesthesial pulmonum, than in the hydrops pectoris, because this medicine influences powerfully the whole extent of the absorbent system. Squill, in combination with digitalis, for the hydrops pectoris, and if the cellular membrane be anaesthesial, connect steel with both the above medicines. Chrysts of tartar, especially in the anaesthesial pulmonum. Diuretics of other kinds, the same as in general anaesthesial. Opium, in hydrothorax, or dropsy of the chest, without anaesthesial, may be employed, but not in the side. It is sometimes impossible even to relieve the dropsy of incontinence; and the
dyspeptic from this cause can never expect again to enjoy the pleasures of existence in full measure." (Beddoes.)

Genus V. Ascies. Dropsy of the abdomen.

The swelling of the abdomen is tense, scarcely elastic, but fluctuating; the fluctuation can sometimes be perceived by placing one hand on one side of the abdomen, and striking with the other hand on the opposite side. Ascites is attended with scanty of urine, thirst, and after some time a degree of hectic fever.

As a rule, most usually originates through the medium of a diseased liver; and such disease is, in the greater number of instances, itself induced by intemperance in spirituous liquors. Like the disease, however, of the lungs, preceding dropy in the chest, liver complaints productive of ascites, may be brought on by the precipitate application of cold, succeeding to the extremes of heat, by inebriety, mental affections, and other causes. Ascites is also supposed to originate from debility in the abdominal lymphatics, without the intervention of any hepatic disease.

M. M. Ascertain by inquiry into previous and present symptoms, whether any degree of liver complaint has preceded the dyspeptic accommodation; whether there is any disposition to jaundice of the skin; whether the alvine excretions are insufficient, whitish, and slimy; whether there has been any pain in the region of the liver, difficulty of tying on the side, especially on the left side, high colour of the urine, pain in the right shoulder, &c., and adapt the treatment accordingly. If the water is independent of disease in the liver, chryscals of tartar, digitals, other diuretics, and steel, may be immediately had recourse to, without the intervention of calomel purgatives and of emetics which last are almost always indicated in the more usual form of ascites, that form a morbid affection of the biliary organs. Emetics in hepatic ascites are often attended with most beneficial effects. "Per vomitus solutum cuncta tenaci, concurrentur obstructa, expelluntur stagnantes, male mirabiliter in urinam proponent." (Boerhaave.) In the administration of asitic purgatives, care must be taken that, from the violence of excitement which they occasion, they do not induce peritoneal inflammation. A combination of gamboge, elaterium, and calomel is frequently employed as a purgative in ascites. Mercurial ointment to the region of the liver. Tonics, especially steel. The inflammation of vital air, as recommended and employed by Dr. Thornton and others. Tapping. This is to be regarded in general as merely a palliative: if however there has not been any very considerable disease of the liver, or the debility is not extremely urgent, tapping may be advised with a prospect of effecting a radical cure, provided due care is at the same time employed to maintain a proper excitement, or, as it is generally expressed, to restore and preserve the tone of the liver system.

Genus V. Hydrometria. Dropsy of the womb.

This, like the physometra, already mentioned, often assumes a deceitful resemblance to pregnancy. It is characterized by dropical swelling, continued to the region of the uterus, not being accompanied by other symptoms of dropy.

It is a disease in which the unmarried and the barren are principally obnoxious; sometimes it follows abortion.

Sect. IV. Solida. Swellings of solid parts.

Genus I. Physiologia. A swelling chiefly occupying a portion of the abdomen, increasing gradually, and neither tense nor resonant as in pneumatic nor fluctuating as in dropy.

This disease is principally formed by a serous state of the several parts, and viscera, which form its seat. These serous enlargements are generally incurable.

Genus II. Rhachitis. Rickets. See infancy.

Older III. Impetiginis.

Deforinities and discolorations of the external surface from general disease.

Genus I. Scrophula. King's evil. Swellings of the lymphatic glands, terminal in ulcer, are perhaps the only proper characteristics of actual scrophula; the thick upper lip, transparent skin, and other appearances which are considered as symptoms of the disease, are merely marks of peculiar predisposition.

A scrophulous habit is merely a susceptibility of disease, arising from torpor in the lymphatic vessels, and when brought on by the agency of exciting causes, constitutes a peculiar action of the lymphatic glands, by which inflammation and at length ulceration, with a discharge of grumous matter, are induced.

Its exciting causes are those which encourage the original debility, and the disease may almost certainly be avoided by attention to diet and regimen; by nutritious food, a pure oxygenous atmosphere, cleanliness, exercise, etc.

When by neglect, the predisposition has been permitted to break out into disease, calomel purges, steat, small doses of digitalis, warm and soothing baths, and phosphates of lead, above all clean and clear ventilation, stimulating nutritious diet. Let the mind be preserved free from the erroneous idea, that to cure scrophula is to purge away gross humours. See Surgery.

Genus II. Syphilis. Venereal disease.

After impure conception, a disorder of the genitals, ulcers in the mouth and nose. Eruptions on the skin of a copper colour, terminating in ulceration; these principally situated near the margin of the hair, blisters on the surface of the body, especially on the surface of the face. Nocturnal pains in the centre of the bones.

N. B. For the local application to venereal ulcers, the more particular treatment of the complaint, and the mode of curing gonorrhoea vulvulina, see Surgery.

Genus III. Strobilus, scurvy.

Indigestion and lassitude; bowels and tumid countenance; gums livid, and disposed to bleed spontaneously, or from the slightest irritation; skin dry, and covered with livid spots; edematous swellings of the ankles. Scurvy appears to originate from want of, or exhaustion of excitement, both in the venous and absorbent system; it is produced by a protracted course of salt food, and by mental depression.

The elephantiasis, phlegmasia, and trichomas, forming the fourth, fifth, sixth, and seventh genera of this order, are diseases of such rare occurrence in this country, as not to require any particular description.

For the more common complaints which require local application, see Surgery.

Genus III. Intemperance.

Symptoms. Yellowness of the skin and eyes; white and shiny faces; high-coloured obstructing the biliary, yellow, bilious, and extreme oppression of spirits.

The yellow colour of the skin, which constitutes jaundice, arises from the diffusion through the system of that bile, which, in the nature of matter, is produced through the biliary ducts into the intestinal canal. This impregnation of the system with bile has been supposed to be effected in three ways, viz. through the medium of the biliary vessels; by the injection of blood; and in the duodenum; and by regurgitation through the hepatic veins, or absorption by the lymphatics of the liver, when the obstruction is in some part of the bile's course previous to its union.

This interruption of the biliary secretion may originate from a spasmodic affection of the duodenum; from chronic inflammations, or other diseases of the liver interfering with the secretion; or from certain concretions lodging in some part of the hepatic organs, called gall-stones; and, as pointed out by Mr. Townsend, from visceral mucus stopping up or obstructing the biliary ducts. Indeed, whatever hinder the bile from passing into the duodenum may prove a source of jaundice.

The first of the above species of jaundice is generally of a temporary nature; it occurs principally in those who have much irritability of habit, in consequence of violent passions, and other sources of spasmatic affections.

The second species is not of so decided a nature; it follows upon a long course of intemperance in spirituous liquors, and is only to be remedied by removing the disease of the liver itself.

The biliary calculi, which give rise to the third species of jaundice, appear, like urinary concretions, to arise from some defective action in the secretory or absorbing vessels of the parts in which they are formed or lodged; as the stone in the bladder, is evidently favoured by a retention of fluid, from which they are formed. It may therefore be inferred, that gall-stones are never, or seldom, produced without some previous jaundice having taken place. Thus they are both the cause and consequence of the disease. Their presence may be ascertained from jaundice frequently disappearing and returning, from the appearance of biliary concretions among the faces, and from the disease being attended with shooting pains in the epigastric region, and right hypochondrium. Nasusae, difficult respiration, and sickness, often likewise accompany this species of jaundice.
The icterus mucosus of Townsend, which is perhaps the most frequent species of jaundice, is unattended either by pain or spasmodic affections; there are no gall-stones observed in the face; but these are generally discharged mixed with much slime and viscidities. It is generally accompanied with, and is most commonly occasioned by, depression of mind, especially when favoured by sedentary habits, breathing an impure atmosphere, living upon unwholesome intubitions, or indulging in the too free use of spirits and tobacco.

While it is the most frequent, and oftentimes the most protracted, of any of the species of jaundice, it is at the same time most easy of cure when properly understood and managed.

In icterus spasmodicus, opium, asaefatica, atrop, electricity. If the skin depends upon any irritations in the stomach: or bowels, these to be removed by emetics, purgatives, anthelmintics. Similarly in intermittent, emetics to facilitate the passage of the gall-stones, and spasmodics. Warm bathing. Enomolent clysters. Vegetable tonics, and steed.

N. B. The average doses of medicines will be found in the articles Materia Medica, and Pharmacy.

MEDEIATAS LINGUE, a jury or inquest impaneled, whereas the one-half consists of natives or denizens, the other strangers; and used in pleas wherein the one party is a stranger, the other a denizen.

MEDIAM, in logic, the mean or middle term of a syllogism, being an argument, reason, or consideration, for which we affirm or deny any thing; or, it is the cause where the greater extremity is affirmed or denied of the les in the conclusion.

MEDEIUM, or MEAN, geometrical. See MEAN.

MEDULLA OBLONGATA. See ANATOMY.

MEDULLA SPINALIS. See Anatomy.

MEDUSA, a genus of vermes of the order molusca. The generic character is, body gullionated, generally generally flat underneat: mouth central beneath. The animals of this genus consist of a tender gelatinous mass of different figures, furnished with arms or tentacular processes, proceeding from the lower surface: the larger species, when touched, cause a slight tingling and redness, and are usually denominated sea-nettles; they are supposed to constitute the chief food of cetaceous fish, and most of them shine with great splendour in the water. There are 44 species. See Plate Nat. Hist. fig. 202.

MEIONITI, a mineral found only among the lava of Vesuvius, always crystallized. Prismatic form, a prism whose bases are squares. It occurs usually in eight-sided prisms, and terminated by four-sided pyramids. Sometimes the edges of the prism are truncated. Colour greyish-white; fracture flat; melts before the blowpipe into a white spongy glass. MEL, a genus in the family of the natural order syngenia polygama necessary. The calyx is five-leaved; recept. cathe, chystical; down one-leaved, involuted, converging.

There are three species, herbs of the West Indies.

MELETITE, a mineral found in the neighborhood of Vesuvius, and formerly called the green glass. It is black or brownish. Crystalized in six-sided prisms, terminated by trihedral summits. It is composed of 40 silica. 28.5 alumina. 10.0 oxides of iron 10.0 magnesia. 3.5 lime. 0.25 oxide of manganese.

MELEAGRICA, a genus of the polyandria order, belonging to the polyandria class of plants. The calyx is quinquepartite, superior; the corolla pentapetals; the filaments are very numerous, and collected in such a manner as to form five pencils: there is one style; the capsule is half-celled with the calyx, formed like a berry, and is trivalved and trilocular. The species are 11, natives of India and the South Sea Islands. The most remarkable species is the leucodendron, from the leaves of which (or brown-leaved leucadendron) the cepalet oil is obtained; a medicine in very high esteem among the Eastern nations, particularly in India. It is said to be obtained by distillation from the fruits of the tree; but brought into this country it is a liquid of a greenish colour, of a fragrant but at the same time a very peculiar colour, and of a warm pungent taste. Some authors, however, represent this oil as being of indescribable quality, a white or colourless fluid; and it has been said by the authors of the Dispensatorium Brunsvicense, when prepared in Europe from the seeds sent from India, to be entirely of this appearance. Whether the oleum cepalet has been but little employed either in Britain or on the continent of Europe; but in India it is used both internally and externally, and is highly extolled for its medical properties. It is applied externally where a warm and peculiar stimulus is requisite; it is employed for restoring vigour after luxations and sprains, and for easing a violent pain in gouty and rheumatic cases, in tooth-sache, and similar affections of the skin; but it has been breathed in taken internally, and it is particularly said to operate as a very powerful remedy against tympanic affections.

MEALPYRUM, cow-wheat, a genus of the angiosperma order, in the duidynemia class of plants, and in the natural method ranking under the 40th order, persoonia. The calyx is quadrifid; the upper lip of the corolla is compressed, with the edges folded back; the capsule is bicolour and oblique, opening at one side: there are two gynious seeds. There are five species, four of them natives of Britain, and growing spontaneously among corn-fields. They are excellent food for cattle and fowls. It tells us, that where they abound, the yellowest and best butter is made. Their seeds, when mixed with bread, give it a ducky colour; and, according to some authors, produce a vertigo, and other disorders of the head; but this is denied by Mr. Withering, though he allows that they give it a bitter taste.

MELESTOMA, the American gooseberry tree, a genus of the monogyria order, in the decandria class of plants, and in the natural method ranking under the 17th order, caly-
fatigued, and take to the highest trees, where they will suffer themselves to be shot one after another, if within reach of the marksman. They were first seen in France under the reign of Francis I. and in England in that of Henry VIII. By the date of the reign of these monarchs, the first turkeys must have been brought from Mexico, the conquest of which was completed A.D. 1521.

The turkey he began to lay early in the spring, and will often produce a great number of eggs, which are white, marked with redish or yellow spots, or rather flecks. She sits on the first of her crop; of which in this climate she will often have from 14 to 17 for one brood; but she scarcely ever sits more than once in a season, except allowed thereto by putting fresh eggs under her as soon as the first set are hatched; for, as she is a close sitter, she will willingly remain two months on the nest, though this conduct, as may be supposed, is said greatly to injure the bird. Turkeys are bred in quantities in some of the principal counties of England, and are driven up to London towards autumn for sale in flocks of several hundreds, which are collected from the several cottages about Norfolke, Suffolk, and neighbouring counties. The fish is that part of the pelt in which it is worth their while to attend carefully to them, by making these birds a part of their family during the breeding-season. It is pleasing to see what pains the drivers take in picking them up by thousands of a bit of red rag fastened to the end of a stick, which, from their anti-pathy to it as a colour, acts with the same effect as a scourge to a quadruped.

Of the turkey there are several varieties, which have arisen from domestication. The most common is dark-grey, inclining to black, or barred dusky-white and black. There is also a beautiful variety of a fine deep copper colour, with the greater quills pure white, and the tail of a dirty white; it is when old a most beautiful bird. A variety with a pure white plumage is also now not unfrequent, and appears very beautiful. It was once esteemed as a great rarity, and the breed supposed to have been brought in Holland. The salpinus inhabits India, and is sometimes less than the last. See Plate Nat. f.lit. fig. 261.

MELES, in zoology, See Ursus.

MELIA, acaci, or the head-free, a genus of the monotypic order, in the decanthera class of plants, and in the natural method ranking under the 23rd order, tribulina. The calyx is quinquedentate; the petals five; the nectarium, cylindric, as long as the corolla, with its mouth ten-toothed; the fruit is a plum with a quinquangular kernel. There are three species, all of them exotic trees of the latter, rising near 20 feet high, adorned with large pinnate or wangled leaves, and clusters of pentapetalous flowers. They are all of them trees, which have arisen on hot lands.

MELIANTHUS, honey-flower, a genus of the angiospermae order, in the dixymadia class of plants, and in the natural method ranking under the 24th order, corydalis. The calyx is pentaphyllous, with the lowest four petals, and there are four petals, with the nectarium under the lowest ones. The capsule is quadrilocular. There are three species: 1. The major has many upright, ligeous, durable stalks, and from the sides and tops of the stalks long spikes of chocolate-coloured flowers. 2. The minor has upright, ligeous, soft, durable stalks; and from the sides and ends of the branches long, loose, pendulous bunches of flowers tinged with green, saffron-colour, and red. Both the species flower about June; but rarely produce seeds in this country. They are very ornamental, both to foliage and flower, and merit admittance in every collection. They are easily propagated by suckers and cuttings. They thrive best in a dry soil, and in a sheltered warm exposure. 3. The common, h. kernel.

MELICA, rograper, a genus of the digitaria order, in the triandria class of plants, and in the natural method ranking under the 4th order, gramina. The calyx is beaked, baldous, with an embryo of a flower betwixt the two florets. There are three species, of which the most remarkable is the native. It is a native of several parts of Britain, and of the adjacent islands; and it is common in the borders of the stream, the streams make ropes of it for fishing-nets, as it will bear the water for a long time without rotting.

MELICOCCA, a genus of the class and order octandria monogynia. The calyx is four-parted; the petals two; the anthers four; the style is one, and the stigma subulate, drapie coriaceous. There is one species, a tree of South America.

MELICYTUS, a genus of the class and order dioecia pentanthera. There is one species, of New Zealand, little known.

MELISSA, baum, a genus of the digitaria gynoomerica class of plants, with a monopetalous ringed flower, the lower lip of which is divided into three segments, whereof the middle one is cordate; the seeds are four in number, and contained in the bottom of the cup. There are six species.

Baum is greatly esteemed among the common people as good in disorders of the head and stomach; but is less regarded in the shops. It is most conveniently taken in infusion by dissolving a large grain of the drug in a little water, and then adding a little sugar. It is less bitter than the dry, which is contrary to the general rule in relation to other plants.

MELITIS, bastard baum, a genus of the dixymadia gynooemerica class of plants; the upper lip of whose cup is emarginated; the upper lip of its flower is plain, and is the lower one crested. There are two species.

MELIUS INQUIRENDUM, in law, a writ that lies for a second inquiry to be made of what lands, &c. a man died seized; when the party is suspected upon the writ deman clause.

MELLISÆ. This genus of salts is but imperfectly known, in consequence of the scarcity of mellicale. It has been examined only by Klaproth and Vanquelin, and even by them too slightly to admit a description of their properties. The following are all the facts hitherto ascerained:

1. When mellicale is neutralized by potass, the solution crystallizes in long prisms.
2. When mellicale is saturated by ammonia, the solution yields flat transparent needles transparent crystals, which become opaque when exposed to the air, and assume the white colour.
3. When mellicale is deprived of amonia, the solution yields green transparent silica crystals, which become opaque when exposed to the air, and assume the white colour.
4. When mellicale is dissolved into barytes water, strotian water, or lime water, a white powder immediately precipitates, which is dissolved by adding a little more of the acid.
5. When the acid is mixed with a solution of sulphat of lime, very small gritty crystals precipitate, which do not destroy the transparency of the water; but the addition of a little ammonia renders the precipitate flaky.
6. When this acid is mixed into a solution of a salt, a flat precipitate appears, which is dissolved by adding more acid. With mutrari of barytes it produces no precipitate; but in a short time a group of transparent needle-form crystals is deposited, consisting most likely of sulphuric acid.
7. When this acid is mixed into sulphat of alumina, it throws down an abundant precipitate in the form of a white flaky powder.

MELITE, hornstone, needle of alumina. This mineral was first observed about 100 years ago in Thuringia, between the layers of wood coal. It is of a honey-yellow colour (whence its name); and is usually crystallized in small octahedrons, whose angles are often transcluted. Fracture conchoidal. Specific gravity, according to Abich, 1.666. When heated it whitens, and in the open air burns without being sensibly charred. A white matter remains, which effervescs slightly with acids, and which at first has no taste, but at length leaves an acid impression upon the tongue.

Klaproth analysed the melilit in 1799, and ascertained it to be a compound of alumina and a peculiar acid, to which he gave the name of mellicale. A more accurate research was soon after confirmed by M. Vanquelin. MELLITIC ACID has been found only in the melilit. It may be procured from that mineral by the following process: Reduce slowly to powder in about 72 times its weight of water. The acid combines with the water, and the alumina separates in flakes. By filtering the solution, and evaporating sufficiently, the mellic acid is obtained in the state of crystals.

These crystals are either very fine needles, sometimes collected into globules, or small short prisms. They have a brownish colour, and are at first sweetish-sour, and afterwards bittersweet.

This acid is not very soluble in water; but the precise degree of solubility has not been ascertained. When exposed to heat, it is timelessly decomposed, yielding an abundant smoke, which however is despicable of smell. A small quantity of insipid ashes remains behind, which do not alter the colour of litmus paper.

All attempts to convert it into oxalic acid by the action of nitric acid have failed. The nitric acid merely caused it to assume a straw-yellow colour.

The effect of the simple bodies on this acid has not been tried. It combines with alka-
hils, earths, and metallic oxides, and fori
with them, which are distinguished by
the name of minerals. The properties of these
compounds will be considered afterwards.

From the analysis of M. Euphrate, we
learn that the mixture is composed of
40 parts of conic acid
16 parts of alumina
33 parts of water

100.

From other analyses by the same chemist,
he infers that metallic acid is composed of
carbon, hydrogen, and oxygen, but the pro-
portions are not yet known.

MELOCHIA, Lethe melbola, a genus of the peacandia order, in the monadelphia class of plants, and in the natural m-th order
ranking under the 37th order, columnaria.
The capsule is quinquelocular and monosper-
rous. There are 14 species: but the only
remarkable one is the peacandia, or common

MELODICUS, a genus of the class and order
peacandia digynus. It is contain;
sect. in the middle of the tube, stellate; berry
two-celled, many-seeded. There is one spe-
cies, a shrub of New Caledonia.

MELODY, in music, the agreeable effect of
different sounds, ranged and disposed in
succession; so that melody is the effect of a
single voice or instrument, by which it is dis-
tinguished from harmony.

MELOE, a genus of insects of the order
coleoptera: the generic character is
monadelphia, with the last joint oval; tho-
rasful; wing-sheaths soft, flexible; head
inflected. Among the principal species of
meleoe may be numbered the meloe procac-
bus, commonly called the oil-beetle. It is
of considerable size, often measuring near
an inch and a half in length: its colour is
violace-black, especially on the antennae
and limbs; the wing-sheaths are very short, in
the female insect especially, scarcely cover-
ing more than a third of the body, and are of
an oval shape. This species is frequent in the
advanced state of spring in fields and pas-
ture, creeping slowly, the body appearing so
swollen or distended with oil as to cause the
insect to look like a ball. On being
handled it suddenly exudes from the joints
of its legs, as well as from some parts of the
body, several small drops of a clear, deep-
yellow oil or fluid is very peculiar and
generally an evidence of a male insect
with difficulty. On being
handled it suddenly exudes from the joints
of its legs, as well as from some parts of the
body, several small drops of a clear, deep-
yellow oil or fluid is very peculiar and
generally an evidence of a male insect

MELON. See Cucumis.

MELONIA, a genus of the mono-
gynia order, in the triandria class of plants,
and in the natural method ranking under the
34th order, cucurbitacae. The calyx is
quinquelocular; the corolla campanulated and
monosperous. There is only one species, viz.
the pendula, a native of Carolina, Virginia,
and also many of the American islands. The
plants strike out roots at every joint, which
fasten themselves into the ground, by which
means its stalks extend to a great distance
each way. The flowers are very small, in
shape like those of the meloe, of a pale sul-
phur-colour. The plant is a native of the West Indies,
grows to the size of a pea, and of an oval figure,
and changes to black when ripe; these are
by the inhabitants sometimes picked when
they are green. In Britain the fruit are much
smaller, and are not so hard to find than them.
The plants are too tender to be reared in this
country without
artificial heat.

MELYRIS, a genus of insects of the order
coleoptera: the generic character is
antennae
entirely perforated; head inflected under the
thorax; thorax margined; lip closed, enarginate; jaw one-toothed, pointed. To ere
the three species. See Plate Nat. Hist. fig. 264.

MEMBRANE. See Anatomy.

MEMECYLON, a genus of the octan-
gynia monogynia class and order. The calyx
is superior; corolla one-petalled; anth.
inserted in the side of the apex of the filament;
berry crowned with cylindrical calyx. There
are three species, trees of the East Indies.

MEMORY, artificial, a method of
writing the name of forming certain
words, the letters of which shall signify
the date or era to be remembered. In
order to this, the following series of vowel, diphi-
thongs, and consonants, together with their
corresponding numbers, must be exactly
learned, so as to be able at pleasure to form
a technical word, that shall stand for any
number, or to resolve such a word already formed.

\[
\begin{array}{cccccccc}
1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 \\
1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 \\
\end{array}
\]

The first five vowels, in order, naturally re-
present 1, 2, 3, 4, 5; the diphthong au = 6, as
being composed somewhat beyond for the like reason, eu = 7, and eu = 9. The
diphthongs ed will easily be remembered for, as
being the initials of the word. In like manner,
where the initial consonants could conveniently
be retained, they are made use of to signify the
number, as for 3, f for 4, s for 6, and s for 9. The rest were assigned without any particular
reason, may be more easily remembered for 7 or septem, f for 8, or k, or moni-
der for 9, or duo; k for 1, as being the first conson-
ant; and l for 5, being the Roman letter for 50:
and among others that could have been put in
their places.

It is farther to be observed, that a and i being
made use of to represent the cophphers, why
certainly the greater number of the
butterflies, than in the case of the earlier
artificial, the numbers assigned begin with 1, instead of a repetition of a and i, e and e,
&c. instead of a repetition of e and s, y and y, &c.
for 100, 300, 500, 900, &c.

Fractions may be set down in the
following manner.
\[
\frac{a}{b} + \frac{c}{d} = \frac{a}{b} + \frac{c}{d}
\]

This is the principal part of the method,
which consists in expressing numbers by
artificial words. The application to history
and chronology is also performed by artificial
words. The art herein consists in making
such a change in the ending of the
name of a place, person, planet, coin, &c.
without altering the beginning of it, as shall
really suggest the thing sought at the
same time that the beginning of the word
being preserved, shall be a leading or
prompting syllable to the ending of it so
changed. Thus, in order to remember the
years in which Cyrus, Alexander, and
Julius Cæsar, founded their respective mo-
carchs, the following words may be form-
ed; for Cyrus, Cyrus; for Alexander, Alex-

MEM.
A mineral, nearly of the same nature with the one just described, has been found in Bavaria. Its specific gravity is only 3.7. According to this fact of Naumann and Hecht, it is composed of 49 oxide of titanium; 33 iron; 2 magnesium; 14 oxide combined with the iron and manganeous; 100.

A specimen of the same ore from Botany Bay has been lately analysed by Mr. Cheeseman.

MENAIS, a genus of the pentadactyla monogynia class and order. The calyx is three-leafed; the corolla salver-shaped; berry four-celled; seeds solitary. There is one species, a herb of South America.

MENDICANTS, or begging friars, several orders of religious in popish countries, who, having no settled revenue, are supported by the charitable contributions they receive from others.

MENISCUS, a genus of the cryptogama siliace. The capsules are helped in crescents interposed between the veins of the pod.

There is one species, a native of the West Indies.

MENISPERM. See OPTICS.

MENISPERMUM, a genus of the dioecia dodecandra class and order. The male petals are four outer, eight inner; stamina sixteen; female corolla, as in the male, stem; eight; barrel; berries two, one-seeded. There are 13 species, herbs of the East Indies.

MENNONITES, a sect of Baptists in Holland, so called from Mennon Simonis of Friesland, who lived in the sixteenth century. This sect believe that the New Testament is the only rule of faith; that the terms person and trinity are not to be used in speaking of the Father, Son, and Holy Ghost; that the first man was not created perfect; that it is unlawful to swear or to wage war upon any occasion; that infants are not the proper subjects of baptism; and that ministers of the gospel ought to receive no salary. They all unite in pleading for toleration in religion, and do not mourn from their assemblies who leave them, and form and own the scriptures for the word of God.

MENSES. See PHYSIOLOGY.

MENSTRUALM, in chemistry, the fluid in which a solid body is dissolvd. Thus water is a menstruum for salts, and gums; and alcohol for resins.

MENTHIA, a genus of the polyandria monogynia class and order. The cal; is five-leafed; cor. five-petalled; cap. inferior; cylindric, many-seeded. There is one species, an annual of South America.

MENYANTHUS, buckbean, a genus of the pentadactyla monogynia class of plants, with a monopetalous funnel-like flower, divided into five deep segments at the limbs; the fruit is an oval capsule with one cell, containing a great many small seeds. There are five species.

Buckbean, called by authors trifolium patens, and pataudium, is greatly recommended as a diuretic in dropsical cases; as also for the cure of intermittent fevers, and disorders of the urinary organs. It is a plant of easy cultivation, and the roots are used, either fresh or by decoction, for culinary purposes, the spermatic is preferred to the other two; but for medicinal use, the peppermint and pennyroyal have almost entirely superseded it. A conserve of the leaves is very grateful; and the distilled waters both simple and spiritual, are universally thought pleasant. Dr. Lewis says, that dry mint digested with rectified spirit, in a ratio of two parts of mints to one part of spirits, when this is strong weed, is useful in convulsive fits; and is also the best remedy for the quinsy, which appears by day-light of a fine dark-green, but by candle-light of a bright red colour. The fact is, that a small quantity of this tincture is green either by day-light or by candle-light, but a large quantity it seems insipuous to common day-light; however, when placed between the eye and a candle, or between the eye and the sun, it appears red.

The virtues of mint are those of a warm stomachic, capable of relieving colicky pains, and the gripes, to which children are subject. It likewise proves a useful cordial in languors and faintness. When prepared with rectified spirit, the whole virtues of the mint are extracted. The expressed juice contains only the astringent and bitter parts, together with the mucilaginous substance common to all vegetables. The peppermint is much more pungent than the others.

Pennroyal has the same general characters with the mint, but is more acrid and less agreeable when taken into the stomach. It was long held in great esteem in hysteric complaints, and supposed to have virtues more peculiar than any other plant, but its effects are trifling. It is observable, that both water and rectified spirit extract the virtues of this herb by infusion, and likewise elevate the greatest part of them by distillation.

MENZELIA, a genus of the polyandria monogynia class and order. The cal; is five-leafed; cor. five-petalled; cap. inferior, cylandric, many-seeded. There is one species, an annual of South America.

MERCATON's projection of maps. See MAP.
It is evident that the close connection of this subject with the affairs of men would be of very early recommendation, and accordingly the greatest among them have paid the utmost attention to it; and the chief and most essential discoveries in geometry in all ages have been made in consequence of their practical relations. Socrates thought that the prime use of geometry was to measure the ground, and indeed this business gave name to the subject; and most of the ancients seem to have had no other end in view; and besides measurement, he laid all their geometrical disquisitions. Euclid's Elements are almost entirely devoted to it; and although there are contained in them many properties of geometrical figures, which may be applied to other purposes, and indeed of which the modellers have made the most material uses in various disquisitions of exceedingly different kinds; notwithstanding this, Euclid himself seems to have adapted them cutely to his end, all is considered that his Elements contain a continued chain of reasoning, and of truths, of which the former are successively applied to the discovery of the latter, one proposition depending on and leading to the other. Euclid's propositions still approximating towards some particular object near the end of each book; and when at the last we find that object to be the quality, proportion, or relation between figures, the square, rectangular plane, and solid; it is scarcely possible to avoid allowing this to have been Euclid's grand object: Accordingly he determined the chief properties in the mensuration of rectilinear plane and solid figures, and arranged all such planes, and cubed all such solids. The only curve figures which he attempted besides are the circle and sphere; and when he could not accurately determine their measures, he gave an excellent method of approximating to them, by showing how in a circle to inscribe a regular polygon which should not touch another circle, concentric with the former, although their circumferences should be ever so near to each other; for lying between any two concentric spheres to describe a polyhedron which should not any where touch the inner one: and approximations to this aim have been given to the ancient and modern authors. He always considered that the determination of the circumference of a circle is the chief aim of geometry. He also reduced the circumference of the circle to the diameter of the circle; and so reduced the quadrature of the circle to the determination of the ratio of the diameter to the circumference; which until the times of Archimedes had not yet been found. Being disappointed of the exact quadrature of the circle, for want of the rectification of its circumference, which all his methods would not effect, he proceeded to assign an useful approximation to it; this he effected by the numerical calculation of the perimeters of the inscribed and circumscribed polygons; from which calculations he appears that the perimeter of the circumscribed regular polygon of 192 sides is to the diameter, in a less ratio than that of 3.1415926535897932 (says Mr. Lightfoot) to 1, and that the inscribed polygon of 96 sides is to the diameter in a greater ratio than that of 3.1415926535897932 to 1; and consequently that much more than the circumference of the circle is to the diameter in a less ratio than that of 3.1415926535897932 to 1, but greater than that of 3.1415926535897932 to 1: the first ratio of 3.1415926535897932 to 1, reduced to whole numbers, gives that of 22 to 7, for 3.1415926535897932: 1; 22: 7, which ratio therefore will be a good approximation to the circumference of the diameter. From this ratio of the circumference to the diameter he computed the approximate area of the circle, and found it to be the square of the diameter as 11 to 14. He likewise determined the relation between the circle and ellipse, with that of their similar parts. The hyperbola too, in all probability, he attempt ed: but it is not to be hoped, that he met with any success, since approximation to its area are all that can be given by all the methods that have since been invented.

Besides these figures, he has left us a treatise on the spiral described by a point moving uniformly along a right line, which at the same time moves with an uniform angular motion; and determined the proportion of its area to that of its inscribed circle, as also the proportion of their sectors.

Throughout the whole works of this great man, which are chiefly on mensuration, he everywhere discovers the deepest design, the most beneficial inventions (with Euclid exceedingly careful of admitting into his demonstrations nothing but principles perfectly geometrical and unquestionable) and although his most general method of demonstrating the relations of curved figures to straight ones, is by inscribing polygons in them, yet to determine those relations, he does not increase the number and diminish the magnitude of the sides ad infinitum; but from the plain fundamental principle, allowed in Euclid's Elements, viz. that any quantity may be so often multiplied, or added to itself, as that result shall exceed any fixed quantity of the same kind, he proves that to deny his figures to have the proposed relations, would involve an absurdity. He demonstrated also many properties, particularly in the parabola, by means of the regular paravola which are similar to the inscribed figures; but without considering such series to be continued ad infinitum, and then summing up the terms of such infinite series.

He had another very curious and singular contrivance for determining the measures of figures, in which he proceeds as it were mechanically by weighing them.

Several other eminent men among the ancients who have dealt in this subject, held no small credit and after Euclid and Archimedes: but their attempts were usually upon particular parts of it, and according to methods not essentially different from theirs. Among these are to be reckoned Thales, Anaxagoras, Pythagoras, Bryson, Antiphon, Hippocrates of Chios, Plato, Apollonius, Philo, and Rhetor: most of whom wrote of the quadrature of the circle; and those after Archimedes, by his method, usually reduced the approximation to a greater degree of accuracy.

Many of the moderns have also prosecuted the same problem of the quadrature of the circle, after the same methods, to greater lengths: such are Vieta and Mersenne, whose proportion between the diameter and circumference is that of 113 to 355, which is within about \( \frac{1}{7000} \) of the true ratio; but above all Leibniz, with a still more amazing degree of accuracy, he determined the ratio of the circumference to the diameter to be \( \frac{3.1415926535897932}{4} \cdot \), making it that of \( 3.1415926535897932 \) to 4. See Circle.

Hence it appears, that all or most of the material improvements in the principles or methods of treating of geometry, have been made especially for the improvement of this chief part of it, measurement, which abundantly shews the dignity of the subject; subject success, and therefore, we may say, after mentioning some other things, deserves to be more curiously weighed, because from hence a name is imposed upon that mother and mistress of the rest of the mathematical sciences, which is employed about proportions, and which is wont to be called geometry (a word taken from ancient use, because it was first applied only to measuring the earth, and fixing the limits of possession); though the name seemed very ridiculous to Plato, who substitutes in its place the more extensive name of metrics or mensuration; and others after him give it the title of gnomometry, because it teaches the method of measuring the kinds of phenomena and phenomena of the earth. See Heights, Surveys, Leveling, Geometry, and Gauging.

MERCURIALIS, mercury, a genus of the former order, in the daisy class of plants, and in the natural system under the 38th order, triticaceae. The calyx of the male is tripartite; there is no corolla, but 9 or 12 stamina; the anther is globular and twined. The female calyx is tripartite; there is no corolla, but two styles; the capsule is bicoccous, bilocular, and monospermous. There are six species.

Of these, the perennis, according to Mr. Lightfoot, is of a soporific and delirious nature, noxious both to man and beast. There are instances of those who have eaten it by mistake, instead of the chenopodium bonusHenricus, or English mercury, and have thereby lost their lives, or inventions in plain words, that the French make a syrup of the juice of the annua, another species, two ounces of which are given as a purgative; and that they use it in pessaries and plasters, mixing one part of house to one and a half of the juice. Dr. Withering differs greatly from Lightfoot concerning the qualities of the perennis. "This plant, (says he), dressed like spinach, is very good eating early in the
Mercury.

spring, and is frequently gathered for that purpose. It is said to be beneficial to sheep. Mr. Macnab relates the ease of a man, his wife, and three children, who experienced highly deleterious effects from eating it fried with bacon; but this was probably when the spring was more advanced, since that plant had become acrimonious. When steeped in water, it affords a fine deep-blue colour. Sheep and goats eat it; but cows and horses refuse it.

Mercury, called also quicksilver, was known in the remotest ages, and seems to have been employed by the ancients in gliding and in separating gold from other bodies, just as it is by the indians. Its colour is white, and similar to that of silver; hence the names hydrargyrus, argentum vivum, quicksilver, by which it has been known in all ages. It has no taste nor smell. It possesses a good deal of brilliancy; and when its surface is not tarnished, makes a very good mirror. Its specific gravity is 13.638. At the common temperature of the atmosphere, it is always in a state of fluidity. In this respect it differs from all other metals. But this metal solid when exposed to a sufficient degree of cold. The temperature necessary for freezing this metal is—39°, as was ascertained by the experiments of Mr. Macnab at Hinde's-day. The congelation of mercury was accidentally discovered by the Petersburgh academicians in 1739. Taking the advantage of a very severe frost, they plunged a thermometer into a mixture of snow and salt, in order to ascertain the degree of cold. Observing the mercury stationery, even after it was removed from the mixture, they broke the ball of the thermometer, and found the metal frozen into a solid mass. This experiment has been repeated very often since, especially in Britain. Mercury contracts considerably at the instant of freezing; a circumstance which misled the philosophers who first witnessed its congelation. They supposed that in its thermometer it stuck so much before it froze, that they thought the cold to which it had been exposed, much greater than it really was. It was in consequence of the rules laid down by Pardies, and by dry, but Mr. Macnab was enabled to ascertain the real freezing point of the metal.

Solid mercury may be subjected to the blows of a hammer, and may be extended without breaking. It is therefore malleable; but neither the degree of its malleability, nor its ductility, nor its tenacity, has been ascertained.

Mercury boils when heated to 609°. It may therefore be totally evaporated, or distilled from one vessel into another. It is by distillation that mercury is purified from various metallic bodies, with which it is often contaminated. The vapour of mercury is invariable and elastic like common air; like air, too, its elasticity is indefinitely increased by heat, so that it breaks through the strongest vessel. Gothic, at the desire of an alchemist, once placed a quantity of it in an iron globe, strongly secured by iron hoops, and put the apparatus into a furnace. Soon after the globe became red-hot, it burst with all the violence of a bomb, and the whole of the air was disappared.

Mercury is not altered by being kept under water. When exposed to the air, its surface is gradually tarnished, and covered with a black powder, owing to its combining with the oxygen of the atmosphere. But this change goes on very slowly, unless the mercury is either heated or agitated, by shaking it, for instance, in a large bottle full of air. By either of these processes, the metal is converted into oxide; by the first, into a black-coloured oxide; and by the first, into a red-coloured oxide. This metal does not seem to be capable of combustion.

The oxides of mercury at present known are four in number, viz.

1. The protoxide was first described with accuracy by Boerhaave. He formed it by putting a little mercury into a bottle, and tying it to the spoke of a mill-wheel. By the constant agitation which it thus underwent, it was converted into a black powder, to which he gave the name of ethiops per ye. This oxide is readily formed by agitating impure mercury in a vessel. If it be a black powder, it is without any of the black laster, has no taste, and is insoluble in water. According to the experiments of Fourcroy, it is composed of 90 parts of mercury and 4 of oxygen, and is thus exposed to a strong heat, oxygen gas is emitted, and the mercury reduced to the metallic state. In a more moderate heat it combines with an additional dose of oxygen, and assumes a red colour.

2. When mercury is dissolved in nitric acid without the assistance of heat, and the acid is made to take up as much mercury as possible, it has been demonstrated, by the experiments of Mr. Macnab, that the proportions of mercury and nitric acid are at most 97.6 per cent. of oxygen. Of course an oxide is formed, composed of 89.3 parts of mercury and 10.7 parts of oxygen. This is the dextro-oxide of mercury. This oxide of mercury, or its protioxide, is exposed to a heat of about 609°, it combines with additional oxygen, assumes a red colour, and is converted into an oxide which, in the present state of our knowledge, we must consider as a tritioxide. This oxide may be formed two different ways: 1. By putting a little mercury into a flat-bottomed glass bottle or matras, the neck of which is drawn out into a very narrow tube, putting the matras into a sandbath, and keeping it constantly at the boiling point. The height of the matras, and the smallness of its mouth, prevent the mercury from making its escape, while it affords freeness to the air. The matras contains the protoxide, and becomes black, and then red, by combining with the oxygen of the air: and at the end of several months the whole is converted into a red powder, or rather into small crystals, of a very deep red colour. Thence, when thus obtained, was formerly called precipitate per se. 2. When mercury is dissolved in nitric acid, evaporated to dryness, and then exposed to a pretty strong heat in a porcelain cup, it assumes, when triturated, a brilliant red colour. The powder thus obtained was formerly called red precipitate, and possesses the properties of the oxide obtained by the former process.

This oxide has an acrid and disagreeable taste, possessing poisonous qualities, and acts as an escharotic when applied to any part of the skin. It is somewhat soluble in water. When triturated with mercury it gives out part of its oxygen; and the mixture is converted into protioxide or black oxide of mercury. When heated along with zinc, or tin filings, it sets these metals on fire. According to Fourcroy, it is composed of 92 parts of mercury and 8 of oxygen. But the analysis of Mr. Chevrix, to be described hereafter, gives, for the proportion of its component parts, 85 parts of mercury and 15 parts of oxygen.

The red oxide of mercury, prepared in the usual way, is not pure, but always contains a portion of nitric acid. If we dissolve it in muriatic acid, and precipitate it again, it finds the same when we consider, and retains a portion of muriatic acid. It was in this state that it was examined by Chevrix.

The difficulty of procuring this oxide in a state of purity, and the uncertainty respecting it, may, in some measure, account for the different results obtained by different chemists in their attempts to ascertain its proportions.

Fourcroy has observed, that when oxygen is introduced through the red oxide of mercury, it combines with an additional dose of oxygen, and is converted into a peroxide; but as this peroxide cannot be procured in a separate state, we are ignorant of its composition.

Mercury does not combine with carbon or hydrogen; but it unites readily with sulphur and with phosphorus.

When two parts of sulphur and one of mercury are triturated together in a mortar, the mercury graduall y disappears, and the whole assumes the form of a black powder, formerly called ethiops mineral. This scarcely possible by any process to combine the sulphur and mercury so small globules of the metal may not be detected by a microscope. When mercury is added slowly to its own weight of melted sulphur, and the whole is stirred, the same black compound is formed.

Fourcroy had suggested, that in this compound the mercury is in the state of black oxide, absorbing the necessary portion of oxygen from the atmosphere during its combination with the sulphur. But the late experiments of Front have shown that this is not the case. Berthollet has made it probable that ethiops mineral contains sulphuretted mercury. Hence we must consider it to be composed of three ingredients, namely, mercury, sulphur, and sulphuretted hydrogen. Such compounds are at present denominated by chemists hydrogenous sulphurates. Ethiops mineral is therefore called hydrogenous mercury. When this substance is heated, part of the sulphur is disappared, and the compound assumes a deep violet colour.

When heated red-hot, it sublimes; and if a proper vessel is placed to receive it, a cake is obtained of a fine red colour. This cake was formerly called cinnabar; and when reduced to a fine powder, is well known in medicine under the name of vermilion. It has been hitherto supposed a compound of
the oxide of mercury and sulphur. But the experiments of Priest have demonstrated that the amalgam contains is in the metallic state. According to that very accurate chemist, it is composed of 83 parts of mercury and 13 of sulphur. It is therefore sulphuret of mercury.

The amalgam of mercury has a scarlet colour, more or less beautiful, according to the mode of preparing it. Its specific gravity is about 10. It is tasteless, insoluble in water, and in muriatic acid, and not altered by exposure to the air. When heated sufficiently, it takes fire, and burns with a blue flame. When mixed with half its weight of iron filings, and distilled in a stoneware retort, the sulphur combines with the iron, and the mercury passes into the receiver, which ought to contain water. By this process mercury may be obtained in a state of purity. The use of sulphuret of mercury as a paint is well known.

Mr. Pelletier, after several unsuccessful attempts to combine phosphorus and mercury, at last succeeded by distilling a mixture of red oxide of mercury and phosphorus. Part of the phosphorus combined with the oxide, some of it was converted into an acid; the rest combined with the mercury. He observed that the mercury was converted into a black powder before it combined with the phosphorus. As Pelletier could not succeed in combining phosphorus with mercury in its metallic state, we must conclude that it is not with mercury, but with the black oxide of mercury, that the phosphorus combines. The compound, therefore, is not amalgam of mercury, but black phosphuret of oxide of mercury.

It is of a black colour, of a pretty solid consistence, and capable of being cut with a knife. When exposed to the air, it exhales vapours of phosphorus. Mercury does not combine with the simple incombustibles.

Mercury combines with the greater number of metals. These combinations are known in chemistry as amalgams or amalgamation.

The amalgam of gold is formed more readily, because there is a very strong affinity between the two metals. If a bit of gold is dipped into mercury, its surface, by combining with the mercury, becomes almost as silver. The easiest way of forming this amalgam is to throw small pieces of red-hot gold into mercury. The proportions of the ingredients are not determinable, because the amalgam has an affinity both for the gold and the mercury; in consequence of which they combine in any proportion. This amalgam is white, with a shade of yellow; and when composed of six parts of mercury and one of gold, it may be obtained crystallized in four-sided prisms. It melts at a moderate temperature; and when heated sufficiently, the mercury evaporates, and leaves the gold in a state of purity. It is much used in gilding.

The amalgam composed of ten parts of mercury and one of gold, is spread upon the metal which is to be gilt; and then, by the application of a gentle and equal heat, the mercury is driven off, and the gold left adhering to the metallic surface; this surface is then rubbed with a burnish under water, and afterwards burnished.

Dr. Lewis attempted to form an amalgam of platinum, but hardly succeeded alter a

labor which lasted for several weeks. Guy- ton Morveau succeeded by means of heat. He fixed a small cylinder of platinum at the bottom of a tall glass tube and covered it with mercury. The vessel was then placed in a sand-bath, and the mercury kept constantly boiling. The mercury gradually combined with the platinum; the weight of the cylinder was increased, and it became brittle. When heated strongly, it evaporated, and left the platinum partly oxidized. It is remarkable, that the platinum, notwithstanding its superior specific gravity, always swam upon the top of the mercury, so that Morveau was under the necessity of fixing it down. The amalgam of silver is made in the same manner as that of gold, and with equal ease. It forms dentritic crystals, which, according to the Dion academicians, contain eight parts of mercury and one of silver. It is of a white colour, and is always of a soft consistence. Its specific gravity is greater than the mean of the two elements. Gellert has ever remarked that, when thrown into pure mercury, it sinks to the bottom of that liquid. When heated sufficiently, the mercury is volatilized, and the silver remains behind pure.

The affinities of mercury as ascertained by Morveau, and of its oxides as exhibited by Bergman, are in the following order:

**Mercury. Oxide of Mercury.**

**Mercury, in astronomy, the smallest of the planets, and the nearest the sun. See Astronomy.**

**Mercury, in ethnology, a genus of birds of the order of auresae; distinguished by having the beak of a cylindrical figure, and hooked at the extremities, and its dentitions of a subulated form.**

1. The cucullatus, or crested diver of Canada, has a globular crest, white on each side; and the body is brown above, and white below. This elegant species inhabits North America. It appears at Hudson’s-bay the end of May, and builds close to the lakes. The nest is composed of grass, lined with feathers from the breast; the number of eggs from four to six. The young are yellow, and are fit to fly in July. They all depart from thence in autumn. They appear at New York, and other parts, as low as Virginia and Carolina, in November, where they frequent fresh waters. They return to the north in March, and are called at Hudson’s bay, the comika sheep. See Plate Nat. Hist. fig. 265.

2. The merganser, or goosander, weighs four pounds; its length is two feet four inches; the breadth three feet four. The dun-diver, or female, is less than the male; the head and neck are white; the tips of the plumage are white; the breast and middle of the belly are white, tinged with yellow. The goosander seems to prefer the more northern situations to those of the south, not being seen in the last except in very severe weather. It continues the whole year in the Orkneys; and has been shot in the Hebrides in summer. It is common on the continent of Europe and Asia, but most so towards the north.

3. The alidus, or smew, weighs about 34 ounces; the length is 18 inches, the breadth 26; the bill is narrower at the end, and of a lead-colour; the head is adorned with a long crest, white above and black beneath; the head, neck, and whole under part of the body, are of a pure white; the tail is of a deep gold, the legs a white. The male, or loach, diver, is less than the male; the back, the scapulars, and the tail, are dusky; the belly is white. The smew is seen in England only in winter, at which season it sometimes breeds. It is found on some parts of it; as also in France, in the neighborhood of Picardy, where it is called la piette; similar to this, we have heard it called in Kent by the name of magpie diver.

There are three other species. See Astronomy, and Geography.

**Meridian.** See Astronomy, and Geography.

**Meridional Parts, Miles, or Minutes.** In navigation, are the parts by which the meridians in Mr. Wright’s chart (commonly though falsely called Mercator’s) increase as the parallels of latitude decreas; and as the distances of the latitude of any place is equal to the radius or semi-diameter of that parallel, therefore, in the true sea chart, or nautical planisphere, this radius being the radius of the equinoctial, or whole sine of 90°, the meridional parts are the degree of latitude must increase, as the seconds of the arch, contained between that latitude and the equinoctial, do decrease. The tables therefore of meridional parts, which we have in books of navigation, are made by a continual addition of seconds; they are calculated in some books for every degree and minute of latitude; and they will serve either to make or graduate a Mercator’s chart, or to work the Mercator’s sailing. To use them, you must enter the table with the degree of latitude at the head, and the minute on the first column towards the left hand, and in the angle of meeting you will have the meridional parts of both the place you are in; if you use the meridional difference of latitude is found by subtracting the meridional parts answering to the least latitude, from those answering to the
To find the Meridional Parts to any Spheroid, with the same eccentricities as a Sphere. Let the semi-diameter of the equator be to the distance of the centre from the focus of the generating ellipses, as \( m \) to 1. Let \( A \) represent the latitude for which the meridional parts are required, \( x \) the sine of the latitude, to the radius 1. Find the arc \( B \), whose sine is \( -\frac{1}{x} \), take the logarithmic tangent of half the complement of \( B \), from the common tables. Subtract the log. tangent from 10.000000, or the log. tangent of \( 90^\circ \); multiply the remainder by the number \( 785.7044679 \), and divide the product by \( m \); then the quotient subtracted from the meridional parts in the sphere, computed in the usual manner for the latitude \( A \), will give the meridional parts, expressed in minutes, for the same latitude in the spheroid, when it is the oblate one.

Example: If \( m = 1 \), \( 1000 \) to 29, then the greatest difference of the meridional parts in the sphere and spheroid is 760.299 minutes. In other cases it is found by multiplying the remainder above-mentioned by the number 1174.078.

When the spheroid is oblate, the difference in the meridional parts between the sphere and spheroid, for the same latitude, is then determined by a circular arc.

We shall here add a table of meridional parts, calculated by Mr. Mungo, in his new and learned Treatise of Mercator’s Sailing applied to the true Figure of the Earth. By this table may be projected a true chart for any part of the earth’s surface, and the several problems of sailing may be solved by it. Maps of countries may be delineated and applied to the various purposes of navigation, geometry, and astronomy. Nor are the errors of the common spherical projections so very small in many cases, as to be inconsiderable and not dangerous. For instance, if a ship sails from south latitude \( 25^\circ \), to north latitude \( 90^\circ \), and the angle of the course be \( 45^\circ \); then the difference of longitude of the common table would be \( 320^\circ \), exceeding the true difference \( 314^\circ \) by \( 6^\circ \), or rules. Also the distance sailed would be \( 4512 \), exceeding the true distance, \( 4425 \), by \( 87 \), or miles, which errors are too great to be neglected. For other instances of such a correction of the charts, we refer to the author’s admirable book above-mentioned.

MERLIN. See Falcon.

MERLIN, in fortification, is that part of a parapet which is terminated by two embrasures, or the thick part of a lantern or cistern. These are the same with those of the parapet; but its breadth is generally nine feet on the inside, and six on the outside. It serves to cover those on the battery from the enemy; and is better when made of earth well beaten and close, than when built with stones; because the latter are round and would should defend.

MEROPS, in ornithology, a genus belonging to the order of pica. The bill is crooked, fat, and carinated; the tongue is jagged at the point, and the feet are of the walking kind.

The principal species are: 1. The apalier, or bee-catcher, which has an iron-colored back; the belly and tail are of a blueish green; and the throat yellow. This bird inhabits various parts of Europe, on the continent, though not in England. It is said to have been seen in Sweden, and blocks of them have been seen at Annapah in Germany in the month of June. It takes the name of bee-catcher from its being very fond of those insects; but, besides these, it will catch gnats, flies, cicadae, and other insects, on the wing, like swallows.

These birds make their nests in the holes in the banks of rivers, of the sand martin and kingfisher: at the end of which the female lays five to seven white eggs, rather less than those of a blackbird. The nest itself is composed of moss.

2. The virdilis, or Indian bee-eater, is given with black belly, black breast, and the throat and tail black. It is a large bird.

3. The erythropeter, or red-winged beecatcher, is in length six inches; the bill is one inch, and black; the upper parts of the head, body, and wings, the spheroid, or crests, are green brown, on the rump and the tail-coverts; behind the eye is a spot of the same, but of a very deep color; the quills and tail are red, tupp’d with black; the last two inches in length; the throat is yellow; the under parts of the body are a dirty white; and the legs black. There are more than 20 other species.

MESEMBRYANTHEMUM, Figmar--gold, a genus of the pentagynia order, in the icosandra class of plants, the natural method ranking under the 13th order, succulent. The calyx is quinquepart; the petals are numerous and linear; the capsule is fleshy, four-seeded and indehiscent: there are seventy-five species, all African plants, from the Cape of Good Hope, near 40 of which are retained in our gardens for variety. Of these only one is annual, and the most remarkable of them all is called the crystal--lumin, diamond, ficodes, or ice-plant. This singular and curious plant, being closely covered with large pellucid pimples, full of moisture, shining brilliantly like diamonds, is in great esteem. It is a very tender plant when young, and is raised usually from seed by means of cuts. In June it will endure the open air till October, when it perishes; but if placed in a hot-house in autumn it will often live all winter.

The other species are most durable in stem and foliage. Some are shrubby; others pendent, with loose straggling stems, and branches inclining to the ground; while others have no stalks at all; the leaves are universally very thick, succulent, and fleshy, and of various shapes, situations, and directions; while some are punctured, or dotted with transparent points; and some have pellicle. Its use has not been much noticed, as it has not been much mentioned. They afford a very agreeable variety at all times of the year, and merit a place in every collec-
tion. They are greenhouse plants, and are propagated by cuttings of their stalks and branches.

**MESENTERY. See Anatomy.**

**MESNE, he who is lord of a man, and so lastentants of him, yet himself sheds of a superior lord 15 Vin. Alc.**

**MESNE PROCESS, is an intermediate process, and is said to be pending the suit, upon some collateral interlocutory matter, as to summon jurors, witnesses, and the like; sometimes it is put in contradistinction to final process, or process of execution, and then it signifies all such process as intervenes between the beginning and end of a suit. 3 Black. 279.**

**MESPLISUS, the medlar; a genus of the pentagaomy order, in the Rosacea class of plants; and in the natural method ranking under the 30th order, pomaceae. The calyx is quinquelobate; the petals are five; the berry is inferior and pentapetalous.**

There are nine species, the principal of which are, 1. The Germanica, German mespilus, or common medlar, rises with a de- formed button, branching irregularly 15 or 20 feet high; sparse-leaved, yellow, and brown fruit, the size of middling apples, which ripen in October, but are not edible till beginning to decay. The varieties are, common great German medlar; smaller Nottingham medlar; spear-shaped Italian medlar. 2. The arbutus, arbutus-leaved mespilus, has a small, roundish, purple fruit, like haws. 3. The amethyst, or shrubbery medlar, or dwarf medlar. 4. The chamæ- mespilus, or dwarf medlar, commonly called bastard quince, has small red fruit. 5. The cotonéaster, commonly called dwarf quince, with small roundish bright-red fruit. 6. The Cnidosperma, Canada snowy mespilus, with small, purpleish fruit, like haws. 7. The pyracantha, or evergreen thorn, rises with a shrublike, spiny stem, branching diffusely 12 or 14 feet high, all the shoots terminated by much branching white flowers; succeeded by large bunches of beautiful red berries, remaining all winter, and exhibiting a very ornamental appearance.

**MESSENGERS, are certain officers chiefly employed under the direction of the secretary; the secretaries always in readiness to be sent with all kinds of dispatches foreign and domestic. They also, by virtue of the secretaries' warrants, take up persons for high treason, or other offences against the state. The prisoners they apprehend are usually kept at their own houses, for each of which they are allowed 6s. 8d. per day, by the govern-ment; and when they are sent abroad, they have a stated allowance for their jour-ney.**

**METALS may be considered as the great instruments of all our improvements; without them, many of the arts and sciences could hardly have existed. So sensible were the ancients of the great importance, that they raised those persons who first dis- covered the art of working them to the rank of deities. In chemistry, they have always filled a conspicuous station; at one period the whole science was founded upon them; and it may be said to have owed its very existence to a rage for making and transmuting metals. 1. One of the most conspicuous properties of the metals is a particular brilliancy which they possess, and which has been called the metallic lustre. If a piece of any of the metals is rubbed on a cloth and then placed in direct contact with the eyes, and the surface of the skin, it will be found that the rays from the surface of the metal enter the eye, and produce in it a sense of brightness, and this while a piece of the metal is held up to the eye. 2. They are transparent, or impervious to light, even after they have been reduced to very thin plates. Silver leaf, for instance, is so thin that it does not permit the smallest ray of light to pass through it. Gold, however, when very thin, is not absolutely opaque: for gold leaf is so thin that it appears to the eye, and the light, of a lively green; and must therefore, as Newton first remarked, transmit the green-coloured rays. 3. There are a number of metals, as the same as gold, and which transmit a trivial degree of light; if they could be reduced to a proper degree of thinness. 4. There is a part of the excellence of the metals, as copper, which is, owing; their brilliancy alone would not equalize them for that purpose. 5. They may be melted by the application of heat, and then still retain their opacity. This property enables us to cast them in moulds, and then to give any shape we please. In this manner many ele- gant iron utensils are formed. Different met- als differ exceedingly from each other in fusibility. Mercury is so very fusible, that it is always fluid at the ordinary temperature of the atmosphere; while other metals, as platinum, cannot be melted except by the most violent heat which it is possible to pro- duce. 6. Their specific gravity is much greater than that of any other body that is known in anatomy. That the lightest of them, is more than six times heavier than water; and the specific gravity of platinum, the heaviest of all the metals, is 23. This great density, no doubt, contributes con- siderably to the value and utility of that great quantity of light which constitutes the metallic lustre. 7. They are the best conductors of elec- tricity of all the bodies hitherto tried. 8. None of the metals are very hard; but some of them may be hardened by art to such a degree as to exceed the hardness of almost all other bodies. Hence the nume- rous cutting instruments, and the modern make of steel, and which the ancients made of a combination of copper and tin. 9. The elasticity of the metals depends upon their hardness, and it may be increased by the same process by which their hardness is increased. Thus the steel of which the balance-springs of watches are made, is almost perfectly elastic, though iron in its natural state possesses little elasticity. 10. One of their most important properties is malleability, by which they present the capacity of being pounded and flattened when struck with a hammer. This property, which is peculiar to metals, enables us to give the metallic bodies any form we think proper, and thus renders it easy for us to convert them into the various instruments for which we have occasion. All metals do not possess all these qualities; but it is remark- able that almost all those which were known to the ancients have it. Heat increases this property considerably. Metals become harder and denser by being hammered for a long time; this property, which is also wanting in many of the metals, is ductility; by which we mean the capacity of being drawn out into wire, by being forced through holes of various diameters. 11. Ductility depends, in some measure, on another property which metals possess, namely, tenacity; by which is meant the power which a metallic wire of a given diame- ter has of resisting, without breaking, the action of a weight suspended from its extremity. Metals differ exceedingly from each other in their tenacity. An iron wire, for instance, 1/4 of an inch in diameter, will support, without breaking, about 500l. weight; whereas a lead wire, of the same diame- ter, will not support more than 15l.

11. When exposed to the action of heat and air, most of the metals lose their lustre, and are converted into earthy-like powders of different colours and properties, according to the metal and the degree of heat employed.

12. If any of these calxes, as they are called, is mixed with charcoal, and exposed to a strong heat in a proper vessel, it is changed again to the metal from which it was produced. This fact is easily ex- plained on the principles of modern chemist- ry; the calx is the metal combined with ox- ygen, or an oxide, in modern language, and by heating it with charcoal, which has a stronger attraction for oxygen, than substance is taken from the metal, and it is brought back again to the metallic state. This process, uniting with the charcoal, forms carbonic acid gas.

The words calx and calculation, then, are evidently improper, as they convey false ideas; philosophers therefore now employ, instead of them, the words oxide and oxida- tion, which were invented by the French chemists. A metallic oxide signifies a metal united with oxygen; and oxidation implies the act of that union.

13. Metals, then, are all capable of combi- ning with oxygen; and this combination is sometimes accompanied by combustion, and sometimes not. The new compounds formed are called metallic oxides, and in some cases metallic acids. These were formerly distin- guished from each other by their colour. One of the oxides, for instance, was called black oxide, another was termed red oxide; but it is now known that the same oxide is capable of being converted according to circumstances. The mode of naming them from their colour, therefore, wants precision, and is apt to mislead; es- pecially as there occur different examples of the same metal having the same colour.

As it is absolut-ly necessary to be able to dis-tinguish the different oxides of the same
metal from each other with perfect precision, and as the present chemical nomenclature is defective in this respect, we may, till some better system is adopted, distinguish them from each other, by prefixing to the word oxide the first syllable of the Greek ordinal numerals. Thus the protoxide of a metal will denote the metal combined with a minimum of oxygen, or, the first oxide which the metal is capable of forming: deuteroxide will denote the second oxide of a metal, or the metal combined with two doses of oxygen. When a metal has combined with as much oxygen as possible, the compound formed is denoted by the term peroxide; indicating by it, that the metal is thoroughly oxidized.

Thus we have the term oxide to denote the combination of metals with oxygen in general; the term protoxide and peroxide to denote the minimum and maximum of oxidation; and the terms deuteroxide, triroxide, &c., to denote all the intermediate states which are capable of being formed.

14. Metals may be also of combining with the simple combustibles. The compounds thus formed are denoted by the simple combustible which enters into the combination, with the termination uret added to it. Thus the combination of a metal with sulphur, phosphorus, or carbon, is called the sulphuret, phosphuret, or carburat of the metal. Hydrogen has not been proved capable of entering into similar combinations; neither have the simple metals, oxygen.

15. The metals are capable likewise of combining with each other, and of forming compounds, some of which are extremely useful in the manufacture of instruments and utensils. Thus pewter is a compound of lead and tin; brass, a compound of copper and zinc; bell-metal, a compound of copper and tin. These metallic compounds are called by chemists alloys, except when one of the combining metals is mercury. In that case the compound is called an amalgam. Thus the compound of mercury and gold is called the amalgam of gold.

16. The metals at present amount to 23; only 11 of which were known before the year 1750. They may be very conveniently arranged into the following classes: namely, 1. Malleable metals; 2. Brittle and easily fusible metals; 3. Brittle and difficultly fusible metals. The metals belonging to each of these classes will be seen from the following Table:

It seems most probable that these names were first given to the planets; and that the seven metals, the only ones then known, were considered as having some relation to the deities of the planets or to the Gods that inhabited them, as the number of both happened to be the same. It appears from a passage in Origen, that these names first arose among the Persians. Why each particular metal was denominated by a particular planet, it is not easy to say. Many conjectures have been made, but scarcely any of them are satisfactory.

As to the characters by which these metals were expressed, astrologers seem to have considered them under the attributes of the deities of the same nature. The circle, in the earliest periods among the Egyptians, was the symbol of divinity and perfection; and seems with great propriety to have been adopted as the character of the earth, especially as, when surrounded by small strokes projecting from its circumference, it may form some representation of the emblem of rays. The semicircle is, in like manner, the image of the moon; the only one of the heavenly bodies that appears under that form to the naked eye. The character \( \alpha \) is supposed to represent the scythe of Saturn; \( \beta \) the thunderbolt of Jupiter; \( \gamma \) the crescent of Mars, together with his shield; \( \alpha \) the looking-glass of Venus; and \( \delta \) the caduceus or wand of Mercury.

Professor Beckmann, however, who has examined this subject with much attention, thinks that these characters are merely abbreviations of the old names of the planets. "The character of Mars (he observes), according to the oldest mode of representing it, is evidently an abbreviation of the word Espur, in the Greek manuscripts understood to signify; or, in other words, the first letter \( \alpha \), with the last letter \( \alpha \) placed above it. The character of Jupiter was originally the initial letter of \( \zeta \) and \( \gamma \); and the two last letters of the name of the planet, or its mathematical and astrological works of Julius Firmicus, the capital \( Z \) only is used, to which the last letter \( \alpha \) was afterwards added at the bottom, to render the abbreviation more distinct. The supposed looking-glass of Venus is nothing else than the initial letter distorted a little of the word \( \varphi \\\alpha\rho\upsilon\omicron\upsilon \), which was the name of that god. The imaginary scythe of Saturn has been gradually formed from the two first letters of his name \( \Sigma\alpha\rho\upsilon\omicron\upsilon \); and, during the invention of the signs used by the Greek philosophers for the sake of dispatch, made always more convenient for use, but at the same time less perceptible. To discover in the pretended caduceus of Mercury the initial letter of his Greek name \( \Sigma\alpha\omicron\omicron\nu \), one needs only look at the abbreviations in the oldest manuscripts, where he will find that the \( \Sigma \) was once written as \( \zeta \); they will remark, also that transcribers, to distinguish this abbreviation from the first still preserved, placed the \( C \) thus \( \delta \), and added under it the next letter \( \alpha \). If those to whom this deduction appears improbable will only take the trouble to look at other Greek abbreviations, they will find many that differ still farther from the original letters they express than those of \( \zeta \) and \( \alpha \) united. It is possible also that later transcribers, to whom the origin of this abbreviation was not known, may have endeavored to give it a greater resemblance to the caduceus of Mercury. In short, it cannot be denied that many other astronomical characters are real symbols, or a kind of proper hieroglyphics, that represent certain attributes of circumstances, like the characters of Aries, Leo, and Taurus, explained by Sammasa."
The destructive elastic fluids, which so frequently are disseipated in the cavities of mines, and particularly the carbonic acid gas, and different species of mixed hydrogen gases, may be less prejudicially injurious, among the most formidable enemies of miners. Galleries, fires, ventilators, inflammations by means of torches held at a great distance in those parts of the mines which are unpurposed, and theivable strong door, or barricado, which the workmen place at the moment when they find by the particular sound of the rock, that the waters are coming in upon them, which barricado, by separating them from the liquid, gives them time to save themselves.

have agreed in calling metaphysical: such were the discussions between Clarke and Leibnitz concerning the free agency of man; such were the disputes concerning identity and diversity, which formerly agitated the schools, and which the great philosophers have laid to rest, and if we were called upon to point out a most able and rational work, into which metaphysics are introduced with propriety and ability, we should name Cutworth's Intellectual System.

METEORIS. See Anatomy.

METEOR. This term is by some writers made to comprehend all the visible phenomena of meteorology, but it is more generally confined to luminous bodies appearing suddenly at uncertain times, and with more or less of motion in the atmosphere. These may be reduced under three classes, viz. fire-balls, falling or shooting stars, and ignes fatui.

Those phenomena which are classed together under the general appellation of fire-balls, were divided by the ancients into several branches, according to the external form or appearance of the bodies. They were also regarded by them in a much more formidable light than by us; as being the certain prognostics of great and awful events in the civil and political world. Even the philosophic Cicero distinguished the "ignea facies," as the certain harbingers or indications of those bloody scenes which in his time convulsed and desolated the Roman commonwealth.

Under the general name of comets, Pliny enumerates a variety of these phenomena. If the fire commences at one extremity of the meteor, and burns by degrees, he terms it, from its form and appearance, a lamp or torch; if an extended mass of fire passes longitudinally through the atmosphere, he calls it a dart; and if its length and magnitude are considerable, and it maintains its station for any space of time, it is a bomb; and if the clouds seem to be brought, and exist a quantity of time, it is a tempest; but the last appears to be, strictly speaking, an electrical phenomenon, indeed only a strong and vivid display of lightning.

Several instances of these meteors are recorded by the same author. During the spectacle of gladiators exhibited by Germanicus, one of them passed rapidly by the faces of the spectators at noon-day. A meteor of that species which he calls a beam, he adds, was seen when the Lacedemonians were defeated at sea, in that memorable engagement which lost them the empire at sea. He also mentions a singularly keen meteor, a flame as red as blood, which fell from heaven about the 107th Olympiad, when Philip of Macedon wasconcerting his wicked plan for enslaving the republics of Greece. He relates, that when he was himself on the watch during the night in the Roman camp, he was a spectator of a similar appearance—a number of re-plented fires fixed upon the pickets of the camp, similar, he says, to those which mariners speak of as attaching themselves to the masts and yards of a ship.

In tropical climates these meteors are more common and more stupendous than in these more temperate regions. "As I was riding in Jamaica," says Mr. Barbraham, "one morning past the camp, situated about three miles south-west from St. Jago de la Vega, I saw a ball of fire, appearing to me about the bigness of a bomb, swiftly flying down with a great blaze. At first I thought it fell into the town; but when I came nearer, I saw many people gathered together, a little to the northward, in the savannah, to whom I rode up, because of their meeting: they were admiring, as I found, the ground's being strangely broken up and ploughed by a ball of fire, which, as they said, fell down there. I observed there were many holes in the ground, one in the middle of the bigness of a man's head, and five or six smaller round about it, of the bigness of one's fist, and so deep as not to be fathomed by such implements as were at hand. It was observed also, that all the green herbage was burnt up near the holes; and there continued a strong smell of sulphur near the place for some time after." 

Ulysses gives an account of one of a similar kind at Quito. "About nine at night," says he, "a globe of fire appeared to rise from the side of the mountain Pichincha, and so large, that it spread a light over all the part of the earth facing that mountain. The house where I happened to be at that very time, I was surprised with an extraordinary light darting through the crevices of the window-shutters. On this appearance, and the bustle of the people in the street, I hastened to the window, and could not but take occasion to see it, in the middle of its career, which continued from the west to south, till I lost sight of it, being intercepted by a mountain that lay between me and it. It was round, and its apparent diameter about a foot; it was observed to rise from the sides of Pichincha, although, to judge from its course, it was beyond that mountain where this concrescences of inflammable matter had appeared. In the first half of its visible course it emitted a prodigious effulgence, then it began gradually to grow dim; so that, upon its disappearing behind the intervening mountain, its light was very faint." 

But this kind are very frequently seen between the tropics, and to the northward of 30 degrees latitude; but they sometimes also visit the more temperate regions of Europe. We have the description of a very extraordinary one, given us by Monta- nari, that he was shown to what great heights, in our atmosphere, these vapours are found to ascend. In the year 1670, a great globe of fire was seen at Bononia, in Italy, about three quarters of an hour after sunset. It passed westward, with a most rapid course, and at the rate of not less than 60 miles in a minute, which is much swifter than the force of a cannon-ball, and at last stood over the Adriatic sea. In its course it crossed over all Italy; and, by computation, it could not have been less than 80 miles above the surface of the earth. In the whole line of its course, wherever it approached, the inhabitants below could distinctly hear it, with a hissing noise, resembling that of a fire-work. Having passed away to sea, towards Corfu, it was heard at last to go off with a most violent explosion, much louder than that of a cannon; and immediately after, another noise was heard, like the rattling of a great cart upon a stony road. This sound, which was probably nothing more than the echo of the former sound. Its magnitude, when at Bononia, appeared twice as long as the moon one way, and as broad the other; so that, considering its height, it could not have been less than a mile long, and half a mile broad. From the height at which this was seen, and the relations to that quarter of the world whence it came, it is not improbable that this terrible globe was kindled on some part of the contrary side of the globe; and thus, rising above the air, and passing in a course opposite to that of the earth's motion, in this manner it acquired its amazing rapidity.

Two of these meteors appeared in this country in the year 1783, of which a most particular and truly philosophical account and ingenious solution may be found in the Philosophical Transactions of the following year; and as his account will apply to many phenomena of the kind, we cannot take any better method to elucidate this part of the subject, than by presenting our readers with a short abstract of this very curious and learned memoir.

The first of the two meteors in question was seen on the 18th of August, and was, in appearance, a luminous globe which rose in the N. N. W. nearly round: it, however, soon became elliptical, and gradually assumed a tall as it ascended, and, in a certain part of its course, underwent a remarkable change, compared to the latter by which it proceeded no longer as an entire mass, but was apparently divided into a cluster of balls of different magnitudes, and all carrying a fiery light behind them, till, having passed the east, and turning consideraby to the south, it gradually descended, and was lost out of sight. The time of its appearance was about sixteen minutes past nine in the morning, and visible about half a minute. It was seen in all parts of Great Britain, at Paris, at Nuits in Burgundy, and even at Rome; and is supposed to have described a tract of 1000 miles at least over the surface of the earth. It appears to have burst and re-united several times; and the first bursting of it which was noticed seems to have been somewhere over Lincolnshire, or perhaps near the commencement of the fens.

This change of color corresponds with the period in which it underwent a change of elevation from its course. If, indeed, the explosion was any kind of effort, we cannot wonder that the body should be deviated by it from its direct line; and on the other hand, it seems equally probable, that it was forced by any cause to change its direction, the consequence would naturally be a separation of its parts along the line of the explosion.

The illumination of these meteors is often so great as totally to obliterate the stars, to make the moon look dull, and even to affect the spectators like the sun itself. When this meteor was observed at Brussels, the moon appeared quite red, and even then it was passed, recovered its natural light. This effect, the doctor remarks, must have depended on the contrast of colour, and shows how large a proportion of the blue rays enters into that light which could even on the silver moon appear to have an excess of red. The body of the fire-ball, even before it burst, did not appear of an uniform brightness, but consisted of such light and dull parts, which were constantly changing their relative positions, so that the whole effect was of the kind as if an intermittent illumination or obliquity of the matter. By the best accounts that could be procured concerning the height of the meteor, it seems...
to have varied from 55 to 60 miles. In these two last particulars it seems to have wonderfully corresponded with some other phenomena of the same kind.

A report was heard at some time after the meteor disappeared, and this report was loudest in Lincolnshire and the adjacent parts, and again in the eastern parts of Kent: the report we may therefore suppose to be the effect of the two explosions; for it is singular that, after it entered the continent: a hissing sound was said also to have accompanied the progress of the meteor. Judging from the height of the meteor, its bulk is conjectured to have been not less than half a mile in diameter; and when we consider this bulk, its velocity cannot fail to astonish us, which is supposed to be at the rate of more than 40 miles in a second.

The other meteor, which appeared on the 4th of October, 1783, at 43 minutes past six in the evening, was much smaller than the former, and of a much shorter duration. It was first perceived to the northward, as a stream of fire, like the common aurora borealis, yelling so violently out into that intensely bright bluish flame, which is peculiar to such meteors. It left behind it a dusky-red streak of fire, and, except this, had no tail, but was nearly globular. After moving for not less than 10 degrees in this bright state, it became suddenly extinct without any explosion. The height of the meteor must have been between 40 and 50 miles; and its duration was not more than four seconds.

The doctor is of opinion, that the general cause of these phenomena is electricity, which opinion liegrounds upon the following circumstances: 1st, The velocity of these meteors, in which they correspond with no other body in nature but the electrical fluid. 2dly, The electrical phenomena attending meteors, the lightning flames, and the sparks proceeding from them, which have sometimes damaged ships and houses in the manner of lightning; and, thirdly, the report or sound, which is the effect of electricity passing from a conductor. As a third argument in favour of this hypothesis, the doctor remarks the connection of meteors with the northern lights. Instances are on record of electric lights seen to join, and form luminous balls, darting about with great velocity, and even leaving a train like fire-balls. The aurora borealis appears to occupy as high, if not a higher, region above the surface of the earth, as may be concluded from the very distant countries to which it has been visible at the same time. 3dly, The most remarkable analogy, the doctor thinks, is the course of at least all the larger meteors, which seems to be constantly from or towards the north or north-west quarter of the heavens. Of above forty different fire-balls described in the Philosophical Transactions, twenty are so described, that it is certain their course was in that direction: only three or four seem to have moved the contrary way; and with respect to the remainder, it is felt doubtful, from the imperfect state of the relations.

Notwithstanding the doctor's ingenious arguments, we cannot subscribe to the opinion, that these phenomena are altogether electrical. The duration of the fire-ball, the unequal consistency of the mass, and several other points in the narration, seem to indicate that the ball consisting of three and four separate masses of an evanescent nature than the electric fire.

The following probably was electrical.

On board the Montague, under the command of admiral Chambers, in lat. 42° 49', on the 1st of November, 1783, about ten minutes before twelve, as the author, Mr. Chambers, was taking an observation, one of the quarter-masters desired he would look to the windward. On directing his eye that way, he observed a large ball of blue fire about three miles distance from them. They immediately lowered the topsails, but it came so fast upon them, that before they could raise the main-tack, they observed the ball rise almost perpendicularly, and not above 40 or 50 yards from the main-children, when it went off with an explosion as great as if hundreds of cannon had been discharged at the same time, leaving behind it a bright red flame; and the main-mast rent quite down to the keel. Five men were knocked down, and one of them was greatly bruised, and the other so severely wounded, as to be done to the ship. Just before the explosion, the ball seemed to be of the size of a large hill-stone.

The shooting or falling star is a common phenomenon, but there is so frequently observed, the great distance and transient nature of these meteors have hitherto frustrated every attempt to ascertain their cause. The connection of these with an active state of the atmosphere or a preternatural cause is certain from observation, and we have more reason to consider them as electric scintillations than as solid or fluid matter in the act of combustion. They precede a change of wind.

Concerning the nature and composition of the ignis fatua, or Will-with-a-wisp, there is less dispute; the generality of philosophers being agreed, that it is caused by some volatile vapour of the phosphoric kind, probably the phosphoric acid, emitted from putrid substances, particularly putrid fish, and those sparks emitted from the sea, or sea-water when agitated, in the dark, correspond in appearance with this meteor. Whitehorses, white swans, and other fictions to be "a vapour shining without heat," and it is usually visible in damp places, about dunghills, burying-grounds, and other situations which are likely to abound with phosphoric matter.

A remarkable ignis fatua was observed by Mr. Derham, in some boggy ground, between two rocky hills. He was so fortunate as to be able to approach it within two or three yards. It moved as he stood; and the natural notion about a dead thistle, till a slight agitation of the air, occasioned, as he supposed, by his near approach to it, caused it to jump to another place; and as he approached, it kept flying before him. He was near enough to satisfy himself that it could not be the shining of glow-worms or other insects: it was one uniform body of light.

M. Becaria mentions two of these luminous apparitions, commonly observed in the neighbourhood of Bologna, and which emitted a light equal to that of an ordinary faggot. Their motions were unequal, sometimes rising, and sometimes sinking towards the earth; sometimes totally disappearing, though in general they subsided about six feet above the ground. They clutured in size and figure: and, indeed, the form of each was fluctuating, sometimes floating like waves, and dropping sparks of fire. He was at Cremona, in a dark night in the whole year in which they did not appear; nor was their appearance at all affected by the weather, whether cold or hot, snow or rain. They have been known to change their colour in order to allure men and generalize greater terrors as any person approached, vanishing entirely when the observer came very near to them, and appearing again at some distance. Dr. Shaw also describes a regular ignis fatua, which he saw in the Holy Land. It was sometimes globular, or in the form of the flame of a candle; and immediately afterwards spread itself so much, as to involve the whole company in a pale nodding-light; and then was observed to contract itself again, and suddenly disappear. In less than a minute; however, it would become visible as before, and run along from one place to another; or would expand itself over more than the space of an acre, and then retire. The atmosphere at this time, he adds, was thick and hazy.

In a supersitious age we cannot wonder that these phenomena have all been attributed to supernatural agency: it is one of the noblest purposes of philosophy to release the mind from the bondage of imaginary errors; and by explaining the modes in which the Divine Providence disposes the different powers of nature, to establish the One First Cause; to teach us to see "God in all, and all in God."

METORIC STONES. Almost all the larger fire-balls have been observed to disappear with a loud explosion; and it was almost constantly affirmed that heavy stonebodies fell from them. But though several well-authenticated accounts of the fall of such stones had been from time to time published, it was not till recently that they did indeed attract the attention of philosophers, till Dr. Chladni published a dissertation on the subject in 1794. Two years after, Mr. King published a still more complete account of examples, both ancient and modern; many of them supported by such evidence that it was impossible to reject it. These two dissertations excited considerable attention: but the opinion that stones had really fallen from the atmosphere was considered as so extraordinary, and so contrary to what we know of the constitution of the air, that most people hesitated, or refused to admit it. Meanwhile Mr. Howard took a different method of investigating the subject. He not only collected all the recent and well-authenticated accounts of the fall of stone bodies, and examined the evidence of their truth, but procured specimens of the stones which were said to have fallen in different places, compared them together, and subjected them to a chemical analysis. The result was, that all these stone bodies differed completely from every other known stone: they all contained a superstitious kind of stone; and that they are all composed of the same ingredients. His dissertation on the subject was published in the Philosophical Transactions for 1802. The proofs which this ascri-
Meteoric Stones.

The stony bodies when found are always hot. They commonly bury themselves some distance under the ground. Their size differs from a few ounces to several tons. They are usually roundish, and always covered with a black crust. In many cases they smell strongly of sulphur. The black crust, from the analysis of Howard, consists chiefly of oxide of iron.

The outer surface of these stones is rough. When broken, they appear of an ash-grey colour, and of a granular texture like a coarse sandstone. When examined with a microscope, four different substances may be discovered, of which the stone is composed: 1st. A number of spherical bodies, varying in size from a pin's head to a pea, of a greyish-brown colour, opaque, breaking easily in every direction, of a compact texture, capable of scratching glass, and of giving a few feeble sparks with steel. 2d. Fragments of pyrites of an indeterminate shape, of red, yellow, dull, or yellowish, and quite easily reduced to powder. The powder has a black colour. 3d. Grains of iron in the metallic state, scattered like the pyrites through the stone. 4th. The three substances just mentioned are cemented together by a fourth of an earthy consistence, and so soft that all the other substances may be easily separated by the point of a knife or the nail, and the stone itself crumbling to pieces between the fingers. This cement is of a grey colour. The proportion and size of these different constituents vary considerably in different specimens; but all of them bear a striking resemblance to each other. Their specific gravity varies from 3.3376 to 4.281.

From the analysis of Howard, which was conducted with much precision and address, and which has been fully confirmed by Vanquelin and Klaproth, we learn, that the black crust consists of a compound of iron and nickel, partly metallic and partly oxidized. The pyrites consist of iron, nickel, and sulphur. The metallic grains consist of iron, combined with about one-third of its weight of nickel, and the yellow globules are composed of silica, magnesia, iron, and nickel. The count Bournon observes, that these globules resemble the clays of Werner, and that their chemical analysis corresponds exactly with Klaproth's analysis of this mineral. The earthy cement consists of the various substances, and nearly in the same proportions, as the globular substances. But it will be necessary to exhibit a specimen of some of the analyses, as published by the philosophers to whom we are indebted for them. A stone which fell at Benares in India, was analyzed by Howard. The pyrites consisted of:

A stone which fell in Yorkshire, deprived as much as possible of its metallic particles, gave Mr. Howard from 150 grains,
then the same original; and this accordingly is almost the uniform opinion of philosophers. Klaproth has shown, that real native iron

upon the whole, we may consider these stony and metallic masses as fragments of fire-balls which have burst in the atmosphere; but the origin of the fire-balls will perhaps for ages baffle all the attempts of philosophers to explain them.

meteorology, the doctrine of meteors, or the study of the variable phenomena of the atmosphere, in which also is commonly included the art of deducing probable conjectures on the future state of the weather.

the latter branch of this science was successfully cultivated by the ancients; and it subsists at this day among those whom necessity, arising from the nature of their occupations, renders diligent in comparing the present appearances of the atmosphere, and circumstances depending on its present state, with the changes which succeed. The apohysms of Virgil, in his Georgics, are beautiful examples of this kind of skill, and possess authority, in an equal degree with poetical merit.

the atmosphere may be considered in respect of the direction of its currents or winds; of the variations in its gravity or pressure; of the change in its temperature; of the state of the electricity which it exhibits; and lastly, as to the visible phenomena which are supposed to depend on the foregoing; and the regular notation of which, together with the other indications, forms the only successful way of prosecuting this study. Since the invention of philosophical instruments, an attention to these has too much superseded the ancients, and, singly considered, the more rational, way of deducing pro-

winds, though proverbially uncertain in some climates, are yet not without a striking degree of regularity and system, if we consider the whole atmosphere; and there is a wind that goes on so constantly in one quarter, that windward, in common speech, stands for eastern, and leeward for western. We want only a more extensive set of observations to render exceedingly probable the following hypothesis: That a large portion of the whole atmosphere moves constantly from east to west round the earth, on and near the equator; that this is supplied and impelled by air from the temperate zones, which bounds the cold air in the polar regions; the heat and moisture which arise in the tropics, and the greater density of the air near the earth's surface, giving an ascending current, and the heat of the sun, as well as the inequality in the atmosphere, producing a descending current.

this case all the water moves indeed towards the gate; but the successive times of beginning the current are very different from the gate back to the head of the canal. Thus, to produce a north-east storm, I suppose some great rarefraction of the air in or near the Gulf of Mexico; the air rising thence has its place supplied by the next more northern, cooler, and therefore denser and heavier air; a successive current is formed, to which our coast and islands give a north-eastern direction.

one storm was observed by Dr. Mitchell in 1802. It began at Charleston on the 21st February, at two o'clock in the afternoon; at Washington, which lies several hundred miles to the north-east, it was not observed till five o'clock; at New York it began at ten in the evening; and at Albany not till day-break of the 22d. Its motion, from this statement, was 1100 miles in 11 hours, or 100 miles in the hour.

a remarkable storm of the same kind, and accompanied by an easterly wind, was observed in Scotland on the 8th of February 1799. It was attended by a very heavy fall of snow, and the motion of the wind was
Meteorology.

The range of the barometer is greater in winter than in summer. Thus at York the mean range of the barometer, during October, November, December, January, February, March, of the year 1774, was 1.42, and for the six summer months, 1.06.

It is probable that the variations of the barometer, as well as those of the thermometer, are susceptible of what we may term a local character for each tract or country differing in climate. This will be most readily discovered by the following mode of investigation: Prepare a sheet of paper ruled in inches and vertical divisions on it, the horizontal ones agreeing with the inches and decimal divisions of the scale of the barometer; the perpendicular, which may be about twice as distant, representing divisions of time. It will thus be evident when each line of observation is at the de-termining midnight, and to mark the days of the month at the top of the column thus placed. On this scale let the several notations of any register of the barometer be set down by means of a dot for each, placed in the part of the scale where it may point out the time and the elevation. The desired number of such dots as may be, drawn through the series of dots, which will represent its mean value, the course of the barometer for the time. It will be found, on comparing a number of these curves, that they characterize, in a certain degree, not only the latitude and season, but the locality of the observations. So that although the most obvious resemblances may be traced in different years of the same register, yet the general appearance of registers from different climates, will be found to differ in all respects. In this way we may be seen at one view both the correspondence between the latitude or elevation above the sea of any place, and the range at that place; and the coincidence between the movements of the barometer, and the other phenomena of the weather. It is obvious that the same mode, and even the various elevations, must be used to serve for temperature also, by marking degrees upon the horizonal lines, and changing the line of the appearance representing tempera-ture, so as to make it readily distinguishable from the other. There is a correspon-dence in this climate between the two instruments, which will thus often become conspicuous. It consists in an elevation of temperature after a rise of the barometer, and even the very same elevation takes place at two o'clock. The following is a part of the table on which these observations are founded, reduced to the English standard.

The mean height of the barometer.
METEOROLOGY.

Which the original movement commenced. After a continued gradual rise on the other hand, there usually occurs a similar depression. Experiments prove that the rising movement is the more rapid of the two. The undulations which are to be found in the curve corresponding to the interval between the phases of the moon, are often accompanied by the appearance of some smaller ones, which appear to be due to occasional and less extensive causes.

It happens also from some principle of the kind above stated, that these movements, which in fair and moderate weather proceed with considerable regularity, on being disturbed by storms, e a not resumed suddenly but by degrees, and the interruption is perceptible for a considerable space afterwards.

In long periods of wet weather, the barometer usually keeps about the mean altitude, rising and falling through a short space with little regularity.

In serene and settled weather it is generally high; and in low calm weather, when the air is inclined to rain, it sinks on high winds, rises highest on easterly and northerly winds, and sinks at the wind from the south. At Calcutta, it is always highest when the wind blows from the north-west and north, and lowest when it blows from the south-east.

Such are the phenomena respecting the variations of the barometer, as far as they can be reduced under general heads. Various attempts have been made to explain them, but hitherto without any great degree of success. The theory of Mr. Laplace appears by far the most plausible, though it is not sufficient to explain all the facts. The following observations may be considered as a kind of abstractive of his theory, except in one or two instances.

It is evident, that the density of the atmosphere is least at the equator, and greatest at the poles; for at the equator, the centrifugal force, the distance from the centre of the earth, and the height of the barometer, are at their maximum, while at the pole they are at their minimum. The mean height of the barometer at the level of the sea, all over the globe, is about 77 inches; and on that account, the density of the atmosphere is the same all over the globe. The weight of the atmosphere depends on its density and height; where the density of the atmosphere is greatest, its height must be least; and, on the contrary, where its density is least, its height must be the greatest. The height of the atmosphere, therefore, must be greatest at the equator, and least at the poles; and it must decrease gradually between the equator and the poles, so that its upper surface will resemble two inclined planes, meeting above the equator in their highest part.

During summer, when the sun is in our hemisphere, the mean heat between the equator and the pole does not differ so much as in winter. Indeed, the heat of northern countries at that time equals the heat of the torrid zone; thus in Russia, during July and August, the thermometer rises to 83°. Hence the early of the atmosphere at the pole, and consequently its height, will be increased.

The upper surface of the atmosphere, therefore, in the northern hemisphere, will be less inclined, while that of the southern hemisphere, from contrary causes, will be much more inclined. The very reverse will take place during our winter.

The density of the atmosphere depends in a great measure on the pressure of the superincumbent column; and therefore decreases, according to the height, as the pressure of the superincumbent column continually decreases. But the density of the atmosphere in the torrid zone will not decrease so fast as in the temperate and frigid zones; because its column is longer, and therefore there is a greater proportion of air in the higher part of this column. This accounts for the observation of Mr. Cassini, that the barometer only sinks half as much for every 200 feet of elevation in the torrid as in the temperate and frigid zones.

The density of the atmosphere at the equator, therefore, though at the surface of the earth it is less, must at a certain height equal, and at a still greater distance, the density of the atmosphere in the temperate zones and at the poles.

A current of air is constantly ascending at the equator, and part of it at least reaches and continues in the higher parts of the atmosphere. From this, we may conclude, it is evident, that it cannot accumulate above the equator, but must roll down the inclined plane which the upper surface of the atmosphere assumes towards the poles. As the superincumbent column of the northern hemisphere is more inclined during our winter than that of the southern hemisphere, a greater quantity of the equatorial current of air must flow over upon the northern than upon the southern hemisphere; and the density of our atmosphere will be greater during winter than that of the southern hemisphere: but during summer the very reverse will take place. Hence the greatest mercurial heights take place during winter, and the range of the barometer is less in summer than in winter.

At the heat in the torrid zone never differs much, the density, and consequently the pressure and the weight of the atmosphere, are about the same all over the globe. Hence the range of the barometer within the tropics is comparatively small; and it increases gradually as we approach the poles, because the difference of the temperature and the density of the atmosphere, increases with the latitude.

The diurnal elevation of the barometer in the torrid zone corresponding to the tides, observed by Mr. Cassini and others, must be owing to the influence of the moon on the atmosphere. This influence, notwithstanding the ingenious attempts of D'Alembert and several other philosophers, seems altogether inadequate to account for the various phenomena of the wind. It is not so easy to account for the tendency which the barometer has to rise as the day advances, which seems to be established by Mr. Cotte's table. Perhaps it may be accounted for by the additional quantity of vapour added to the atmosphere, which, by increasing the quantity of the atmosphere, may possibly be adequate to produce the effect.

The falls of the barometer which precede and follow the great oscillations which accompany, the recent storms and hurricanes, show us, that these phenomena are produced by very great rarefactions, or perhaps destruction of air, in particular parts of the atmosphere. The falls of the barometer, too, that accompany winds, proceed from the same cause.

That the temperature of the air varies considerably, not only in different climates and in different seasons, but even in the same place and in the same season, must be obvious to the most careless observer. This terrestrial variation cannot be ascribed to the direct heat of the sun; for the rays of that luminary seem to produce no effect whatever upon air, though ever so much concentrated; but they warm the surface of the earth, which communicates its heat to the surrounding atmosphere. Hence it happens, that the temperature of the air is highest in those places which are situated to be most warmed by the sun's rays, and that it varies in every region with the season of the year. Hence too the reason why it diminishes according to the height of the air above the surface of the earth. That portion of the earth which lies at the equator, is exposed to the most perpendicular rays of the sun. Of course it is hottest, and the heat of the earth diminishes gradually from the equator to the poles.

The temperature of the air must follow the same order. The air, then, is hottest at the equator, and becomes progressively cooler as it increases from the equator, and its height, according to its height above that portion of the earth which lies at the equator, for the two diminishing progressions of temperature.

1. Though the temperature of the air is highest at the equator, and gradually sinks as we ascend towards the poles, it must not vary much. Hence the range of the barometer within the tropics is comparatively small, and it increases gradually as we approach the poles, because the difference of the temperature and the density of the atmosphere, increases with the latitude.

Hence the mean annual temperature of any degree of latitude, must be greater at the equator than at the poles, the same being true of every other portion of the earth. Hence the mean annual temperature of every degree of latitude, must be greater at the equator than at the poles, the same being true of every other portion of the earth.

This first discovered by Mr. Mayer; and by means of an equation which he founded on it, but rendered considerably plainer and simpler, Mr. Kirwan has calculated the mean annual temperature of every degree of latitude between the equator and the pole. He proceeded on the following principle: Let the mean annual heat at the equator be \( m \), and at the pole \( n \); and for any other latitude, the mean annual temperature of that latitude will be \( m - n \times \sin^2 \theta \). If the temperature of any two latitudes is known, the value of \( m \) and \( n \) may be found. Now the temperature of north latitude \( 40^\circ \) has been found by the best observations to be 0.1°, and that of latitude \( 50^\circ \), 52°. The square of the sine of \( 40^\circ \) is nearly 0.410, and the square of the sine of \( 50^\circ \) is nearly 0.509.

\[
\begin{align*}
    m &\approx 0.41 \times m^n \approx 0.41, \\
    m &\approx 0.58 m^n 52.9, \\
    m &\approx 0.58 n^2 40.9, \\
    m &\approx 0.58 n^2 50.9. \\
\end{align*}
\]

Each of these equations is equal
Table of the Mean Annual Temperature of the Standard Station from to . From this last equation the value of is found to be 53 nearly; and as is nearly equal to 84. The mean temperature of the equator, therefore, is 84°, and that of the pole 31°. To find the mean temperature for every other latitude, we have only to find 88 arithmetic means between 84 and 31. In this manner Mr. Kirwan calculated the following table:

<table>

This table, however, only answers for the temperature of the atmosphere of the ocean. It was calculated for the part of the Atlantic Ocean which lies between the 80th degree of northern and the 45th of southern latitude, and extends westward, as far as the Gulf-stream, and to within a few leagues of the coast of America, and for all that part of the Pacific Steam reaching from latitude 45° north to latitude 40° south, from the 20th to the 27th degree of longitude east of London. This part of the ocean Mr. Kirwan calls the standard; the rest of the ocean is subject to anomalies which will be afterwards mentioned.

Mr. Kirwan has also calculated the mean monthly temperature of the standard ocean. The mean temperature on the average appears to

The mean temperature of April seems to approach very nearly to the mean annual temperature; and as far as heat depends on the action of the solar rays, the mean heat of every month is as the mean altitude of the sun, or rather as the sine of the sun's altitude. The mean heat of April, therefore, and the sine of the sun's altitude, being given, the mean heat of every other month results from the following formula:

tins

The temperature of these months, therefore, must be looked upon as an arithmetical mean between the astronomical and terrestrial heats. Thus, in latitude 51°, the astronomical heat of the month of September is 44°, and the mean annual heat is 32°; therefore the real heat of this month should be

After going through a tedious calculation, found the result to agree so ill with observation, that he drew up the following table, partly from principles, and partly by studying a variety of sea journals:
From this table it appears, that January is the coldest month in every latitude, and that July is the warmest month in all latitudes above 48°. In lower latitudes, August is generally warmest. The difference between the hottest and coldest months increases in proportion to the distance from the equator. Every habitable latitude enjoys a mean heat of 60° for at least two months; this heat seems necessary for the production of corn. Within ten degrees of the poles the temperatures vary very little; neither do they differ much within ten degrees of the equator: the temperatures of different years differ very little near the equator; but they differ more and more as the latitudes approach the poles.

2. That the temperature of the atmosphere gradually diminishes, according to its height above the level of the sea, is well known. Thus the late Dr. Hutton, of Edinburgh, found, that at a thermometer, kept on the top of Arthur's-seat, usually stood three degrees lower than a thermometer kept at the bottom of it. Hence, then, a height of 800 feet occasioned 3° of diminution of temperature. On the summit of Pichincha, the thermometer stood at 3°, as observed by Bouger; while at the level of the sea, in the same latitude, it stood at 84°. Here a height of 15564 feet occasioned a diminution of temperature, amounting to 47°. But though there can be no doubt of the gradual diminution of temperature, according to the height, it is by no means easy to determine the rate of diminution. Euler supposes it to be in a harmonious proportion; but this supposition is contradicted by observations. Sauvage supposes, that in temperate climates the diminution of temperature amounts to 1° for every 287 feet of elevation. But Mr. Kirwan has shewn that no such rule holds, and that the rate of diminution varies with the temperature at the surface of the earth. We are indebted to this philosopher for a very ingenious method of determining the rate of diminution in every particular case, supposing the temperature at the surface of the earth known.

Since the temperature of the atmosphere is constantly diminishing as we ascend above the level of the sea, it is obvious, that at a certain height we arrive at the region of perpetual congelation. This region varies in height according to the latitude of the place; it is highest at the equator, and descends gradually nearer the earth as we approach the poles. It varies also according to the season, being highest in summer, and lowest in winter. M. Bouger found the cold on the top of Pichincha, one of the Andes, to extend from seven to nine degrees below the freezing-point every morning immediately before sunrise. He concluded, therefore, that the mean height of the term of congelation (the place where it freezes during some part of the day all the year round) between the tropics was 15,577 feet above the level of the sea; but in latitude 28° he placed it in summer at the height of 13,449 feet. Now, if we take the difference between the temperature of the equator and the freezing-point, it is evident that it will bear the same proportion to the term of congelation at the equator, that the difference between the mean temperature of any other degree of latitude and the freezing-point bears to the term of congelation in that latitude. Thus the mean heat of the equator being 64°, the difference between it and 32 is 32, the mean height of latitude 28° is 72.3°; the difference between which and 32 is 40.3°; then 15,577 \cdot 40.3 = 12072. In this manner Mr. Kirwan calculated the following table:

<table>
<thead>
<tr>
<th>Lat.</th>

Beyond this height, which has been called the lower term of congelation, and which must vary with the season and other circumstances, M. Bouger has distinguished another, which he called the upper term of congelation; that is, the point above which no visible snow ascends. Mr. Kirwan considers this line as much less liable to vary during the summer months than the lower term of congelation, and therefore has made choice of it to determine the rate of the diminution of heat, as we ascend in the atmosphere. Bouger determined the height of this term in a single case, and Kirwan has calculated the following table of his height for every degree of latitude in the northern hemisphere:

The following rule of Mr. Kirwan will enable us to ascertain the height at any required temperature, provided we know the temperature at the surface of the earth.

Let the observed temperature at the surface of the earth be \( t \), the height given \( h \), and the height of the upper term of congelation for the given latitude be \( z \); then \( h = z + \frac{100}{t} \).

This rule is evidently derived from the rule of the preceding paragraph, and is calculated by supposing the temperature of every degree of latitude to be the same as at the equator, and that the temperature of the equator is equal to the mean temperature of the same degree of latitude.

The temperature required by this rule is obviously that of the lower term of congelation. An example will make this rule sufficiently obvious. In latitude 56°, the heat below being 34°, required the temperature of the air at the height of 500 feet! This theorem is called the principle of the action and reaction of the atmosphere, and is a fundamental theorem in hydrostatics.
METEOROLOGY.

Here \( a = 54 \), \( r = 5339 \), \( n = 52 \) \( \frac{a}{100} = 0.401 \), and \( \frac{r}{100} = 0.401 \times 8.03 \) \( \frac{r}{100} = 8.03 \times \frac{a}{100} = \frac{a}{100} = 5.27 \).

From this method of estimating the diminution of temperature, which agrees remarkably well with observation, we see that the heat diminishes in an arithmetical progression. Hence it follows, that the heat of the air at a distance from the earth is not coming to the ascent of hot strata of air from the surface of the earth, but to the conducting power of the air.

3. This rule, however, applies only to the temperature of the air during the summer months of the year. In winter the upper strata of the atmosphere are often warmer than the lower. There, on this 31st of January, 1776, the thermometer on the summit of Arthur's-seat stood six degrees higher than a thermometer at Hawkhill, which is 834 feet lower. Mr. Kirwan considers his observation, almost uniformly observed during winter, to be a current of warm air from the equator, which rolls towards the pole north during our winter.

4. Such, then, is the general method of finding the mean annual temperature over the globe. There are, however, several exceptions to these general rules, which I now come to mention.

That part of the Pacific Ocean which lies between north latitudes 10° and 60°, is no colder at its northern extremity than 42 miles, and at its southern extremity than 1300 miles; it is reasonable to suppose, therefore, that its temperature will be considerably influenced by the surrounding land, which consists of ranges of mountains covered a great part of the year with snow; and there are besides a great many high, and consequently cold, islands scattered through it. For these reasons Mr. Kirwan concludes, that the temperature is at least four or five degrees below the standard. But we are not yet furnished with a sufficient number of observations to determine this with accuracy.

It is the general opinion, that the southern hemisphere, beyond the 40th degree of latitude, is considerably colder than the corresponding parts of the northern hemisphere. Mr. Kirwan has shown that this holds with respect to the summer of the southern hemisphere, but that the winter in the same latitudes is milder than in the northern hemisphere.

Small seas surrounded with land, at least in temperate and cold climates, are generally warmer in summer and colder in winter than the standard ocean, because they are a good deal influenced by the temperature of the land. The gulf of Bothnia, for instance, is for the most part frozen in winter; but in summer it is sometimes heated to 79°, a degree of heat never to be found in the opposite part of the Atlantic. The German Sea is above three degrees colder in winter, and five degrees warmer in summer, than the Atlantic. The Mediterranean Sea is, for the greater part of its extent, warmer both in summer and winter than the Atlantic, which therefore flows into it. The Black Sea is colder than the Mediterranean, and flows into it.

The eastern parts of North America are much colder than the opposite coast of Europe, and fall short of the standard by about 10° or 12°. On the American side of the air 500 feet above the surface of the earth it is 57° and 72°.

From this method of estimating the diminution of temperature, which agrees remarkably well with observation, we see that the heat diminishes in an arithmetical progression. Hence it follows, that the heat of the air at a distance from the earth is not coming to the ascent of hot strata of air from the surface of the earth, but to the conducting power of the air.

3. This rule, however, applies only to the temperature of the air during the summer months of the year. In winter the upper strata of the atmosphere are often warmer than the lower. There, on this 31st of January, 1776, the thermometer on the summit of Arthur's-seat stood six degrees higher than a thermometer at Hawkhill, which is 834 feet lower. Mr. Kirwan considers his observation, almost uniformly observed during winter, to be a current of warm air from the equator, which rolls towards the pole north during our winter.

4. Such, then, is the general method of finding the mean annual temperature over the globe. There are, however, several exceptions to these general rules, which I now come to mention.

That part of the Pacific Ocean which lies between north latitudes 10° and 60°, is no colder at its northern extremity than 42 miles, and at its southern extremity than 1300 miles; it is reasonable to suppose, therefore, that its temperature will be considerably influenced by the surrounding land, which consists of ranges of mountains covered a great part of the year with snow; and there are besides a great many high, and consequently cold, islands scattered through it. For these reasons Mr. Kirwan concludes, that the temperature is at least four or five degrees below the standard. But we are not yet furnished with a sufficient number of observations to determine this with accuracy.

It is the general opinion, that the southern hemisphere, beyond the 40th degree of latitude, is considerably colder than the corresponding parts of the northern hemisphere. Mr. Kirwan has shown that this holds with respect to the summer of the southern hemisphere, but that the winter in the same latitudes is milder than in the northern hemisphere.

Small seas surrounded with land, at least in temperate and cold climates, are generally warmer in summer and colder in winter than the standard ocean, because they are a good deal influenced by the temperature of the land. The gulf of Bothnia, for instance, is for the most part frozen in winter; but in summer it is sometimes heated to 79°, a degree of heat never to be found in the opposite part of the Atlantic. The German Sea is above three degrees colder in winter, and five degrees warmer in summer, than the Atlantic. The Mediterranean Sea is, for the greater part of its extent, warmer both in summer and winter than the Atlantic, which therefore flows into it. The Black Sea is colder than the Mediterranean, and flows into it.

The eastern parts of North America are much colder than the opposite coast of Europe, and fall short of the standard by about 10° or 12°. On the American side of the air 500 feet above the surface of the earth it is 57° and 72°.
the earth is also probably less frequent from cloud to cloud. The far greater part of the visible phenomena of the weather, after which, being raised by evaporation, is transported from place to place in vapour, and which, physically speaking, is a proper component part of the air. When any means a portion of this is deposited at its confluence, it reappears in minute drops, which are at first uniformly diffused, and lessen the transparency of the air in proportion to their abundance. By the report of those who have ascended the highest mountains, or performed acroatic voyages, there is usually a sufficient quantity of this diffused water, especially towards evening, to become visible from above as a sea of haze. It should seem that this is, in fact, the veil which, being drawn over the sable of the sky, converts it to a blue of various degrees of intensity; or at least that it shares with the transparent air in this effect.

The next stage is either dew, or rather haze, for the latter term is more appropriate to the appearance of dew while it is falling. Here the drops have so far become collected as to form an aggregate faintly defined in the air. To this stage of the phenomena may be reduced under the general term cloud. Out of the latter are formed rain, snow, and hail, by which the product of evaporation is finally restored to the earth. The excess for any given time, of the fall of rain or snow which is evaporated, passes off by the springs and rivers to that grand reservoir which forms the far greater part of the surface of the globe.

Tracts of forest, especially if mountainous, invite the rain, and protect the springs; while the accumulated heat on cultivated plains often causes the clouds to pass over them, or to be dissipated. Clearing of land and culture, therefore, tends to lessen the rain and the rivers; but it is for the interest of agriculture to leave a certain quantity of timber growing, especially in springy lands, and to repair the waste of it by planting; for it is not impossible, that in a series of ages, the atmosphere, in a manner so prepared, may convert a tract of fruitful country into one little better than an African desert.

The mean annual quantity of rain is greatest at the equator, and decreases gradually as we approach the poles. Thus at Granada, Andalusia, 12° N., it is 126 inches Cape Francois, St. Domingo — 19° 46' — 120
Calcutta — 22° 23' — 81
Rome — 41° 54' — 30
England — 33' — 32
Petersburg — 59° 16' — 16.

On the contrary, the number of rainy days is smallest at the equator, and increases in proportion to the distance from it. From north latitude 12° to 43°, the mean number of rainy days is 78; from 43° to 46° the mean number is 103; from 46° to 50° it is 134; from 51° to 60°, 161.

The number of rainy days is often greater in winter than in summer; but the quantity of rain is greater in summer than in winter. At Petersburg the number of rainy or snowy days during winter is 81, and the quantity which falls is 30 inches; while during summer the number of rainy days is nearly the same, but the quantity which falls is about 11 inches.

**METEOROLOGY.**

More rain falls in mountainous countries than in plains. Among the Andes it is said to rain almost perpetually; while in Egypt it falls only 134 times in 46 years; and that which is deposited on the ground, and another at some height perpendicularly above it, more rain will be collected into the lower than into the higher; a proof that the quantity of rain increases as it descends, owing perhaps to the drops attracting vapour during their passage through the lower strata of the atmosphere where the greatest quantity resides. This, however, is not always the case, as Mr. Copland demonstrates by the course of his experiments. He observed also, when the quantity of rain collected into the lower gauge was greatest, the rain commonly continued for some time; and that the greatest quantity was collected in the higher gauge only either at the end of great rains, or during rains which did not last long. These observations are important; and may, if followed out, give us new knowledge of the causes of rain. He observes, that during rain the atmosphere is somewhere or other brought into a state which induces it to part with its moisture; and that the rain continues as long as this state continues. The following appears to have been made on this subject in different places, and was the atmosphere carefully analysed during dry weather, during rain, and immediately after rain, we might soon perhaps discover the reason of the latter.

Rain falls in all seasons of the year, at all times of the day, and during the night as well as the day; though, according to M. Tosillo, a greater quantity falls during the day than the night. The cause of rain then, whatever it may be, must be something which operates at all times and seasons. Rain falls also during the continuance of every wind, but oftenest when the wind blows from the south. Falls of rain often happen likewise during perfect calms.

It appears from a paper published by M. Cotte in the Journal de Physique for Oct. 1791, containing the mean quantity of rain falling at 147 different places, the lat. 11° and 60°, derived from tables kept at these places, that the mean annual quantity of rain falling in all these places is 34.7 inches. Let us suppose then (which cannot be very far from the truth) that the mean annual quantity of rain for the whole globe is thirty-four inches. The superficies of the globe consists of 170,681,012 square miles, or 685,461,408,471,500,000 square inches. The quantity of rain therefore falling annually will amount to 53,337,650,815,020,15,800 cubic inches, or somewhat more than 91,751 cubic miles of water.

The dry land amounts to 33,745,253 square miles; the quantity of rain falling on it annually therefore will amount to 30,960 cubic miles. The quantity of water running annually into the sea is 13,140 cubic miles; a quantity of water equal to which must be supplied by evaporation from the sea, otherwise the land would soon be completely drained of its moisture.

The quantity of rain falling annually in Great Britain may be seen from the following table, which is compiled between north lat. 51° and 54°.

The general mean is 32.9 inches. As the places subject to much rain predominate considerably in this list, it will probably be nearer the truth, if we take the mean annual rain in England and Wales at a quantity not exceeding 32 inches.

In this country it generally rains less in March than in November, in the proportion of 7 to 12. It generally rains less in April than October in the proportion of 1 to 2. In winter rain is generally less than in summer; and when it rains less in May than in September, the chances that it does so are at least 14 to 3: but when it rains plentifully in May (as 1.8 inches or more), it generally rains but little in September; and when it rains plentifully in May, it rains plentifully in September.

Snow is evidently formed by a process of regular crystallisation among minute frozen particles of water floating in the air. It is remarkable, that previous to, and during, the fall of snow in quantity, the temperature continues about 32°. It should seem that the evolution of the constituent caloric of the water produces the same effect when ice is formed in the atmosphere, as when it is formed in water. The structure of a crystal of snow demonstrates that a drop of rain is also formed by the union of a great number of smaller drops. When these come together in the act of freezing, and suddenly form a nucleus of white spongy ice, which, by its extreme coldness, becoming incrustated with clear ice from the water it collects in its descent, constitutes hail as we usually see it. Sometimes, however, the nucleus falls uncrustated, which is a prognosis of sharp jOets.

Hail has been likewise observed perfectly transparent, and having the form of an oblate spheroid, showing that it consisted
METEOROLOGY.

There are three simple and distinct modifications, in any one of which the aggregate of the parts of the cloud, may become increased to its greatest extent, and finally decrease and disappear.

By modification is to be understood simply the structure or manner of aggregation, not the precise form or magnitude, which varies every moment in most clouds. The principal modifications are commonly as distinguishable from each other as a tree from a bush, or the latter from a leaf; although clouds may be continuous, or separate, with respect to each other, have often only the common residuum which exist among trees, hills or lakes, taken generally.

The same aggregate, which has been formed in one modification, upon a change in the attendant circumstances may pass into another.

Or it may continue a considerable time in an intermediate state, partaking of the characters of two or three; and it may also disappear in this stage, or return to the first modification.

Lastly, aggregates, separately formed in different modifications, may unite and pass into one, exhibiting different characters; or a portion of a simple aggregate may pass into another modification, without separating from the remainder of the mass. Hence, together with the simple, it becomes necessary to admit intermediate compound modifications, and to impose names on such of them as are worthy of notice.

The simple modifications are thus named and defined: (See Plate Meteorology.)

Parallel, flexuous, or diverging fibres, extensible in any or in all directions.

Craves or crenat crescents, increasing upward from a horizontal base.

A widely extended, continuous, horizontal sheet, increasing from below.

The intermediate modifications which require to be noticed are:

Small, well defined, roundish masses, in close horizontal arrangement.

Horizontal or slightly inclined masses, attenuated towards a part or the whole of their circumference, concave downward; or undulated, separate, or in groups, consisting of small clouds, having these modifications.

The compound modifications are:

6. Cumulo-stratus. Def. Nubes dense, basin cumuli cum strauctura patentia exhibentes. A dense cloud with the base of the cumulus, but in its upper part extended into a broad flat structure.

The rain cloud. A cloud, or system of clouds, from which rain is falling. It is a horizontal sheet, above which the cirrus spreads, while the cumulus extends laterally, and from it.

Of the cirrus.

Clouds in this modification have the least density, the greatest elevation, and the greatest variety of extent and direction. They are the earliest appearance after severe weather. They are generally indicated by a few threads pencilled, as it were, much in the same way that black inks are delineated. These increase in length, and new ones are at times added likewise. Often the first formed 1 threads serve as stems to support numerous branches, which in their turn give rise to others. The process is usually compared to vegetation or to crystallisation; but it is clearly analogous to the delicate arrangements which exist in the particles of coloured powders, such as chalk, vermilion, &c, when these are projected on a deck of wax, after it has been touched with the knife of a charged Leyden phial. We may consider the particles of water as similarly placed upon or beneath a state of charged air.

Their duration is uncertain, varying from a few minutes after the first appearance to an extent of many hours. It is long when they appear alone, and at great heights, and shorter when accompanied by other, and in the vicinity of other clouds.

This modification, although in appearance almost motionless, is intimately connected with the variable motions of the atmosphere.想像 that cloud of this kind have long been deemed a prophecy of storm. Continued wet weather is attended with horizontal sheets of this cloud, which subsequently, and pass to the cirro-stratus. The cirrus pointing upward is a distant indication of rain, and downward a more immediate or present weather. Before storms they appear lower, denser, and usually in the quarters opposite to those by which the storm arises. Steady high winds may also preceded and attended by streaks running quite across the direction in which they blow. These, by an optical deception, appear to meet in the horizon.

The relations of this modification with the state of the barometer, thermometer, hygrometer, and electroscope, have not yet been attended to.

Of the cumulus.

Clouds in this modification are commonly of the most dense structure. They are formed in the lower atmosphere, and move along with the current which is next the earth.

A small irregular spot first appears, and is as it were the nucleus on which they increase. The lower surface continues irregularly plane, while the upper rises into conical or hemispherical heads.

Their appearance, increase, and disappearance, in fair weather, are often periodic, and keep pace with the temperature of the day. They begin to form after some hours before sunrise, arrive at their maximum at the hottest part of the afternoon, then go on diminishing, and totally disappear about sunset.

But in changeable weather they partake of
of subsidence, as in common cases of precipitation in fluids at rest.

Of the cumulo-stratus.

The different modifications which have been just treated of, sometimes give place to each other: at other times two or more appear in the same sky; but in this case the clouds are in the same modal form, and are in the same plane of elevation, those which are more elevated appearing through the intervals of the lower, or the latter showing dark against the lighter ones above them. When the cumulus increases rapidly, a cirro-stratus is frequently seen to form around its summit, rising thereon as on a mountain; while the former cloud continues discernible in some degree through it. This state continues but a short time. The cirro-stratus quickly becomes denser, and spreads; while the superior part of the cumulus extends itself, and passes into it, the base continuing as before, and the convex protruberances changing their position till they precede, move laterally, and downward. More rarely the cumulo-stratus alone performs this evolution, by the movement or mode of increase of its superior part. In either case, a large lofty dense cloud is formed, which may be compared to a mushroom with a very thick stem. It appears to be preceded by a current of rarefied air, or to pass the cirrus or cirro-stratus. The cirro-cumulus is frequent in summer, and is attendant on warm and dry weather. It is also occasionally, and more sparingly, seen in the intervals of showers, and in winter. A cloud is a sure prognostic of increased temperature. The cumulus is the cloud of the day, of the heavens, or of the air. The cumulus is never seen in the fortune of any other cloud, or to pass the cirrus or cirro-stratus.

Of the cirro-stratus.

This cloud appears to result from the subidence of the fibres of the cirrus to a horizontal position, at the same time that they approach towards each other laterally. The cumulus and stratus are separated by a distance, frequently give the idea of sheets of fish. Yet in this, as in other instances, the structure must be attended to, rather than the form, which varies much; presenting at other times the appearance of parallel bars, interwoven streaks like the grain of polished wood, &c. It is always thickest in the middle, or at one extremity, and extended towards the edge. The distinct appearance of these clouds depends always on the production of this and the last modifications.

The cirro-stratus precedes wind and rain, the near or distant approach of which may sometimes be estimated from its greater or less abundance and permanence. It is almost always to be seen in the intervals of storms. Sometimes this and the cirro-cumulus appear together in the sky, and even alternate with each other in the same cloud, when the different evolutions which ensue are a curious spectacle; and a judgment may be formed of the weather likely to ensue, by observing which modification prevails at last. The cirro-stratus is the modification which most frequently and completely exhibits the phenomena of the solar and lunar halo, and (as supposed from a few observations) the parhelion and paraseleune also. Hence the reason of the prognostic for foul weather commonly drawn from the appearance of halo. This cloud is among those natural indications which may be used as the criterion of the indications of the barometer and hydrometer for rain. It may be reasonably thought to originate from a supervening cold and moist current, occluding precipitation in the atmosphere below, before it is itself to be perceived. Its appearance often indicates the simple act of subsidence, as in common cases of precipitation in fluids at rest.
commences; and the lower clouds, arriving from the windward, move under this sheet, and are successively lost in it. When the latter has parted, or when the sheet breaks, every one's experience teaches him to expect an abatement or cessation of rain. But there often follows, what seems hitherto to have been unnoticed, an immediate and great addition to the quantity of clouds on the cessation of rain, the lower broken clouds which remain rise into cumuli, and the superior sheet puts on the various forms of the cirro-stratus, sometimes passing to the cirrus-cumulus.

If the interval is long before the next shower, the cumulo-stratus usually makes its appearance, which it also does sometimes very suddenly after the first cessation.

But we see the nature of this process more perfectly, in viewing a distant shower in profile.

If the cumulus be the only cloud present at such a time, we may observe its superior part to be momentarily tufted with cirrus. Several adjacent clouds also approach, and unite laterally by subduction.

The cirri increase, extending themselves upward and laterally; after which the shower is seen to commence. At other times the cumulus may have been described relative to the cessation of rain. The cirro-stratus is previously formed above the cumulus; and their sudden union is attended with the production of cirri and rain.

In either case the cirri vegetate, as it were, in proportion to the quantity of rain falling; and give the cloud a character by which it is easily known at great distances, and to which, in the language of meteorology, we may appropriate the nimbus of the Latin:

Quinis ubi ad terras abrupto sidere nimbus
It mare per medium; miraris, heu! prescia longe
Horrescunt cordis agricolæ.—Virgil

When one of these arrises hastily with the wind, it brings but little rain, and frequently some hail or driven snow. In heavy showers the cloud, once formed, increases to windward, the cirri being propagated above and against the lower current, while the cumuli, arriving with the latter, are successively arrested in their course, and contribute to reinforce the shower.

In continued gentle rains it does not appear necessary, for the resolution of the clouds, that the different modifications should come into actual contact. It is sufficient, that there exist two strata of clouds, one passing beneath the other, and each continually tending to horizontal uniform diffusion. It will rain during this state of the two strata, although they should be separated by an interval of many hundred feet in elevation.

As the masses of cloud are always blended, and their arrangement destroyed, before rain comes on, so the reappearance of those is the signal for its cessation. The thin sheets of cloud which pass over during a cloudy day, certainly receive from the humid atmosphere a supply proportionate to their consumption; while the latter prevents their increase in bulk. Hence a seeming paradox, which yet accounts with observation; that for any given hour of a wet day, or any given day of a wet season, the more cloud the less rain. Hence also arise some further reflections on the purpose answered by clouds in the economy of nature. Since rain may be produced by great cold, to fall from the slightest obstruction of the sky, by the nimbus, that is, by two sheets in different states, while the cumulus, or cumulo-stratus, with the most dark and threatening aspect, passes over without letting fall a drop, until their change of state commences; it should seem that the latter are the reservoirs, in which the water is collected from a large space of atmosphere, for occasional and local irrigation in dry seasons, and by means of which it is also arrested at times in its descent, in the midst of wet ones. In this so evident provision for the sustenance of all animal and vegetable life, as well as for the success of mankind in that pursuit so essential to their welfare, in temperate climates, of cultivating the earth, we may discover the wisdom and goodness of the Creator and Preserver of all things.

The nimbus, although in itself one of the least beneficial yet now and then superbly decorated with its attendant, the rainbow, which can only be seen in perfection when backed by the widely extended uniform gloom of this modification.

METEOR. See Architecture.
METRE. See poetry. See Hexameter, Pentameter &c.
METROSIDEROS, a genus of the class and order icosaedra monogyna. The calyx is five-cleft, half superior; petals five; stamens very long, standing out; stigma simple; capsule oval, and Fr. The genus consists of 13 species, of New Holland, &c.
MEZEREON. See Daphne.
MEZZOTINTO. See Engraving.
MIASMA, among physicians, denotes the contagious effluvia of pestilential diseases, whereby they are communicated to people at a distance.
MICA. This stone forms an essential part of many mountains, and has been long known under the names of glaciers Maria, and Muscovy glass. It consists of a great number of thin laminæ adhering to each other, sometimes of a very large size. Specimens have been found in Siberia nearly 25 yards square.
It is sometimes crystallized; its primitive form is a rectangular prism, whose bases are rhombs with angles of 120° and 60°; its integral molecule has the same form. Sometimes it occurs in rectangular prisms, whose bases also are rectangular, and sometimes also in short six-sided prisms; but it is much more frequent in plates or scales of no determinate form, and of an angular shape.

Its texture is foliated. Its fragments flat. The lamellete flexible, and somewhat elastic. Very tough. Often absorbs water. Specific gravity from 2.6356 to 2.9342. Feels smooth, but not greasy. Powder feels greasy. Colour, when pure, silver white or grey, but it occurs also yellow, greenish, reddish brown, and black. Mica is fusible by the blow-pipe into a white, grey, green, or black enamel; and this last is affected by the magnet, a small part being rubbed by it becomes negatively electric.

A specimen of mica, analysed by Vanquezin, contained

Mica has long been employed as a substitute for glass. A great quantity of it is said to be used in the Russian marine for panes to the cabin-windows of ships; it is preferred, because it is not so liable as glass to be broken by the agitation of the ship. It is also used in our navy for lanterns, for the use of the powder-rooms.

MICHELIJA, a genus of the octandria polygynia class of plants, the flower of which consists of eight petals; the fruit consists of a cluster of globose unilocular berries, disposed in a cluster, in which there are four seeds, convex on one side, and angular on the other. There are two species, trees of the East Indies.

MICHAUXIA, a genus of the class and order octandria monogyna. The calyx is 16-parted; corolla wheel-shaped, 8-parted; nect. 8-valved, staminiferous; caps. 8-celled, many-seeded. There is one species, a biennial of Aleppo, resembling the campanula.

MICROMETER, an astronomical machine, which, by means of a screw, serves to measure extremely small distances in the heavens, &c., and that to a great degree of accuracy.

The micrometer consists of a graduated circle (Plate Miscell. fig. 162), of a screw q q, and its index . The threads of the screw are such, that one thread makes 0.1 inch exactly. When it is to be used, the point . is set to the side of the part to be measured, and then the index is turned about with the finger, till the eye perceives the point has just passed over the diameter of that part; then the number of turns, and parts of a turn, shown by the graduated circle, will give the dimensions in parts of an inch, as we shall show by the following example: Suppose it is required to measure the diameter of a human hair, and I observe the index is turned just once round while the point . passes over it; then is the plain diameter of the hair in the image . of an inch. Now if the microscope, D E F, D' E' F', magnifies 6 times, or makes the image 6 times larger in diameter than the object, then is the diameter of the hair itself . of an inch. Also it is to be observed, that as there are ten large divisions, and twenty small ones, on the micrometer plate, so each of those small divisions is the 6th part of an inch. Also if in measuring any part of an object, you observe how many of these smaller divisions are passed over by the index, you will have so many thousandths of an inch for the measurement required.
D and that the GGG, of the ischium. The pubis a tuberosity parietal bladder. The clitoris which is at the same time downwards directed. AB, the vertebrae of the longs, os sacrum, and coccyx. C, the os pubis of the left side. D, the lower part of the rectum. E, the perineum. F, the left labium pudendi. GGG, the uterus.

Fig. 11. shows in a lateral view the face of the child, forced down into the lower part of the pelvis, the chin below the pubes, and the mouth in the same position as the elevation of the surface. AB, the vertebrae of the longs, os sacrum, and coccyx. C, the os pubis of the left side. D, the lower part of the rectum. E, the perineum. F, the left labium pudendi. GGG, the uterus.

Fig. 12. shows the head of the child in the same position as the elevation of the surface. AB, the vertebrae of the longs, os sacrum, and coccyx. C, the os pubis of the left side. D, the lower part of the rectum. E, the perineum. F, the left labium pudendi. GGG, the uterus.

Fig. 13. shows the head of the fetus, strong labour-pains, squeezed into a long form, with a tumour on the vertix, from long compression of the head in the pelvis. K, the tumour on the vertix. L, the forceps. M, the urinary bladder much distended with a little fluid. N, the long pressure of the head against the urethra. N, the under part of the pelvis. O, the os uteri.

Fig. 14. exhibits a front view of the pelvis, the breech of the fetus presenting, and distating the os interna, the membranes having been prematurely ruptured. Fig. 15. represents in a front view of the pelvis, the fetus compressed by the contraction of the pelvis into a round form, the fore parts of the former being towards the inferior part of the latter, and one foot and hand drawn into the pelvis. In this figure, the anterior part of the pelvis is removed by a longitudinal section, through the middle of the foramen magnum. A, the superior portion of the os ilium. BB, the uterus. C, the mouth of the uterus shooting and appearing in OOOO the vagina. D, the inferior and posterior part of the os externum. EEEE, the remaining portion of the os pubis and ischium. FFF, the termion of the os.

Fig. 16. represents the forearms and blunt hook, a, the straight forceps, b, the posterior part of a single blade, c, the blunt hook, which is employed to assist the extraction of the head after the pelvis is opened, by introducing the small end along the car on the outside of the head, to above the under jaw, where the point is to be fixed; the other extremity of the hook being held with one hand, while two fingers of the other are to be introduced into the opening. The small end is useful in abortions, to draw down the secundines when they are not expelled by labour-pains, or cannot be extracted by the fingers. The large hook at the opposite end is useful to assist the extraction of the body when the breech presents, but should be used with much caution.

Fig. 17. A represents the whole bone filled, which, when the operator is not provided with forceps, may sometimes be useful in laborious cases. BB, two views of a pessary for the prolapsus uteri. C, a round pessary which is in more general use than the former. DDD, two views of a female catheter.

Fig. 18. A, represents a pair of curved crotches, locked in the same manner as the forceps: the dotted lines indicate a sheath, contrived to defend the point till it is introduced sufficiently high, and gives a view of the back part of one of the crotches. c, a front view of the point, d, the scissors for perforating the cranium, in very narrow and distorted pelvies.

MIGRATION, of birds. It has been generally believed, that many different kinds of birds annually pass from one country to another, and spend the summer or the winter in some foreign country, and return to their own. It has long been an opinion previously received, that swallows reside during the winter season in the warm southern regions; and Mr. Adamson particularly relates his having seen them at Senegal, when they were obliged to leave their country. But besides the swallow, Mr. Pennant enumerates many other birds which migrate from Britain at different times of the year, and are then to be found in other countries; after which they again leave those countries for Britian.

1. Crows. Of this genus, the hooded crow migrates regularly with the woodcock. It inhabits North Britain the whole year; a few are annually said to breed on Dartmoor, in Devonshire. It breeds also in Sweden and Aithonia, in some parts of France it follows the alteration of its seasons it shifts its quarters, in others it resides throughout the year. Our author is at a loss for the summer retreat of these birds which visit us in such numbers in winter, and quit our country in the spring; and for the reason why a bird whose food is such that it may be found at all seasons in this country, should leave us.

2. Cuckoo. A bird which leaves us in the winter. If its diet is aut sole, as several assert, the cause of its migration is very evident. This bird disappears before winter, and revisits us in the spring, a little earlier than the cuckoo.

3. Wryneck, a bird that leaves us in the winter. Though it be the same with that which breeds in the southern countries, it is said to arrive in winter; that bird either leaves us, or else returns towards the sea-coasts.

4. Hoopoe. Comes to England but by accident. Mr. Pennant once heard of a pair that attempted to winter in a meadow at Seiborne, Hampshire, but were frightened away by the curiosity of people. It breeds in Germany.

5. Grouse. The whole tribe, except the quail, live here all the year round; that bird either leaves us, or else returns towards the sea-coasts.

6. Pigeons. Some few of the ring doves breed here; but the multitudes that appear in winter are so disproportioned to what continues here the whole year, as to make it certain that the greatest part quit the country in the spring. It is most probably they go to Sweden to breed, and return thence in autumn: as Mr. Eekmar informs us, they entirely escape that circumstance. Multitudes of the common wild pigeons also make the northern retreat, and visit us in winter; though numbers breed in the high cliffs in all parts of this island. The turtle also probably leaves us in the winter, at least changes its place, removing to the southern counties.

7. Stare, breeds here. Possibly several remove to other countries for that purpose, since the produce of those that continue
here seems unequal to the clouds of them that appear in winter. It is not unlikely that many migrate into Sweden, whither Mr. Berger observes they return in spring.

8. Thrushes. The fieldfare and the redwing breed their summers in Norway and other cold countries; their food is berries, which abounding in our kingdoms tempt them hither in the winter. The two these, and the Royarton crow, are the only land birds that regularly and constantly migrate into England, and do not breed here. The hawfinch and crossbill come hither at uncertain times as not to deserve the name of birds of passage.

9. Chatterer. The chatterer appears annually about Edinburgh in flocks during winter, and feeds on the berries of the mountain ash. In South Britain it is an accidental visitor.

10. Grosbeaks. The grosbeak and crossbill come hither but seldom; they breed in Austria. The pine grosbeak probably breeds in the forests of the Highlands of Scotland.

11. Bunting. Every genus inhabits the land throughout the year, except the greater brambling, which is forced hither from the north in very severe seasons.

12. Finches. All continue in some part of themselves, except the siskin, which is an irregular visitant, said to come from Russia. The LINNETS shift their quarters, breeding in one part of this island, and move with their young to others. All finches feed on the seeds of plants.

13. Larks, fly-catchers, wagtails, and warblers. All these birds feed on insects and worms; yet only part of them quit these kingdoms, though the reason of migration is the same to all. The nightingale, blackcap, fly-catcher, willow-wren, whinchat, and white-throat, leave us before winter, while the small and delicate golden-crowned kinglet braves our severest frosts. The migrants of this genus continue longest in Great Britain in the southern counties, the winter in those parts being later than in those of the north: Mr. Stillingfleet having observed several wheatears in the Isle of Purbeck on the 18th of November. As these birds are incapable of very long flights, Spain, or the south of France, is probably their winter asylum.

14. Swallow and goat-sucker. Every species disappears at the approach of winter.

WATER-FOWL, CLOVEN-FOOTED.

15. Herons. The white heron is an uncommon bird, and visits us at uncertain seasons; the common kind and the bittern never leave us.

16. Curlews. The curlew breeds sometimes on our mountains; but, considering the vast flights that appear in winter, it is probable that the greater part retire to other countries; the whimbrel breeds on the Grampian hills, in the neighbourhood of Invercauld.

17. Snipes. The woodcock breeds in the moist woods of Sweden, and other cold countries. Some snipes breed here; but the greatest part retire elsewhere, as do every other species of this genus.

18. Sandpipers. The piping continues here the whole year; the ruff breeds here, but retires in winter; the redshank and sandpiper breed in this country, and reside here.

All the others absent themselves during summer.

19. Flamingo and oystercatchers. The long-legged plower and the sandpiper visit us only in winter; the spotted appears in spring and in autumn; yet, what is very singular, we do not find it breeds in South Britain. The oystercatcher lives with us the whole year.

We must remark, that every species of the genus of curlews, woodcocks, sandpipers, and plovers, that forsake us in the spring, retire to Sweden, Poland, Prussia, Norway, and Lapland, to breed; as soon as the young can fly, they return to us again, because the fogs which set in early in those countries totally deprive them of the means of subsisting; as the dryness and hardness of the ground, in general, during our summer, prevents their finding the least of their food. So, most of the genera in search of worms, which are the natural food of these birds.

20. Rails and gallinules. Every species of these two genera continue with us the whole year, excepted, which is not seen here in winter. It likewise continues in Ireland only during the summer-months, when it is very numerous.

FINNED-FOOTED WATER-BIRDS.

21. Phalaropes visit us but seldom; their breeding-place is Lapland and other Arctic regions.

22. Grebes. The great-crested grebe, the black and white grebe, and little grebe, breed with us, and never migrate; the other visit us accidentally, and breed in Lapland.

WEB-FOOTED BIRDS.

23. Avocet. Breed near Fossdike in Lincolnshire, but quit their quarters in winter. They are then shot in different parts of the kingdom; which visit not regularly, but accidentally.

24. Auk and guillemot. The great auk or pinguin sometimes breeds in St. Kilda. The auk, the guillemot, and puffin, inhabit most of the maritime cliffs of Great Britain, and the land-tongues, during summer. The black guillemot breeds in the Bass Isle, and in St. Kilda, and sometimes in Llandinno rocks. We are at a loss for the breeding-place of the other species; neither can we be very certain of the winter residence of any of them, except of the lesser guillemot and black-billed auk, which, during winter, visit in vast flocks the Firth of Forth.

25. Divers, chiefly breed in the lakes of Sweden and Lapland, and in some near the pole; but some of the red-throated divers, the northern, and the imber, may breed in the north of Scotland and its islands.

26. Terns. Every species breeds here, but leaves us in the winter.

27. Petrels. The fulmar breeds in the isle of St. Kilda, and continues there the whole year except September and part of October. The shearwater visits the Isle of Man in April; breed there; and, leaving it in August or the beginning of September, disperses over all parts of the Atlantic ocean. The stormfich is seen at all distances from land on the same vast watery tract; nor is ever found near the shore except by some very rare accident, unless in the breeding-season. Mr. Pennant found it on some little rocky isles, on the north of Skye. It also breeds in St. Kilda. He suspects too that it nests on the Blasquet isles off Kerry, and that it is the gourmand of Mr. Smith.

28. Mergansers. This whole genus is met with among the birds that haunt the lakes and land during summer. Mr. Pennant has seen the young of the red-breasted in the north of Scotland; a few of these, and perhaps of the goosanders, may breed there.

29. Ducks. Of the numerous species that form the genus of one or two that breed here; the swan and goose, the shelduck, the eider-duck, a few shovellers, garganey, and teals, and a very small portion of the wild ducks.

The rest contribute to form that amazing multitude of water-fowl that annually repair from most parts of Europe to the woods and lakes of Lapland and other Arctic regions, to perform the functions of migration and nutrition in full security. They migrate by thousands in September, and disperse themselves over Europe. With us they make their appearance the beginning of October; circulate first round our shores; and, when compelled by severe frost, betake themselves to the lakes and rivers. Of the web-footed fowl there are some of harbinger constitutions than others; these endure the ordinary winters of the more northern countries; but when the cold reigns there with more than common rigour, they repair for shelter to these kingdoms: this regulates the appearance of some of these kinds, as of the wild swan, the swallow-tailed shield-duck, and the different sorts of goosanders which then visit our coasts. But the English statute-mile is fourscore chains, or 1760 yards; that is, 5280 feet. See Chains, Yard, and Foot.

We shall here give a table of the miles in use among the principal nations of Europe, in geometrical paces, 69,000 of which make a degree of the equator.

MILIARY FEVER, a malignant fever, so called from the eruption of certain pustules resembling millet-seeds. See Medicine.

MILIUM, MILLET, a genus of the daisy order, in the tribe of a class of plants; and
MILK.

In the natural method ranking under the 4th order, gramium. The calyx is bifurred and unilobar; the corolla is very short; the stamens and style, like. There are 12 species, of which the most remarkable is the ellusium, or common milk.

MILK, is a fluid secreted by the female of all those animals denominated mammaeans, and intended evidently for the nourishment of her offspring.

The milk of every animal has certain peculiarities which distinguish it from every other milk. But the animal whose milk is most made use of by man as an article of food, and with which, consequently, we are best acquainted, is the cow. Chemists, therefore, have made choice of cow's milk for their experiments.

Milk is a opaque fluid, of a white colour, a slight peculiar smell, and a pleasant sweetish taste. When newly drawn from the cow, it has a taste very different from that which it acquires after it has been kept for some hours.

It is liquid, and wets all those substances which can be moistened in water; but its consistence is greater than that of water, and it is slightly astringent. Like water, it freezes when cooled down to about 30°; but Parmenient and Deyerux, to whom we are indebted for the most complete account of milk, have discovered, that when its freezing-point varies considerably in the milk of different cows, and even of the same cow at different seasons, it also was insufficiently heated; but the same variation takes place in the boiling-point of different milks, though it never deviates very far from the boiling-point of water. Milk is slightly heavier than water, and lighter than blood; but the precise degree cannot be ascertained, because almost every particular milk has a specific gravity peculiar to itself.

When milk is allowed to remain for some time at rest, there collects on its surface a thick unctuous yellowish-coloured substance, known by the name of cream. The cream appears sooner on milk in summer than in winter, evidently owing to the difference of temperature. In summer, about four days of repose are necessary before the whole of the cream collects on the surface of the liquid; but in winter it requires at least double the time.

After the cream is separated, the milk remains a much thinner than before, and it has a blueish-white colour. If it is heated to the temperature of 100°, and a little rennet (which is water digested with the inner coat of a calf's stomach, and preserved with salt) is poured into it, coagulation ensues; and if the coagulum is broken, the milk very soon separates into two solid white parts known by the name of curd, and a fluid part known as whey.

We see that milk may be easily separated into three parts; namely, cream, curd, and whey.

1. Cream is of a yellow colour, and its consistence increases gradually by exposure to the atmosphere. In three or four days it becomes so thick that the vessel which contains it may be inverted without incurring any loss. In eight or ten days in air, its surface is covered with a yellowish matter, and it has no longer the flavour of cream, but of very fat cheese. This is the process for making what in this country is called cream cheese.

Cream possesses many of the properties of an oil. It is specifically lighter than water; it has an altogether different consistence in the manner of oil; and if it is kept fluid, it contracts at last a taste which is very analogous to the rancidity of oil. When kept boiling for some time, a little oil makes its appearance through its surface. Cream is neither soluble in alcohol nor in oils. These properties are sufficient to show us, that it contains a quantity of oil; but this oil is combined with a part of the curd, and mixed with some serum; cream, then, is composed of a peculiar oil, curd, and serum. The oil may be easily obtained separate by agitating the cream for a considerable time. This process, known to every bobby, is called churning. After a certain time, the cream separates into two portions; one fluid, and resembling creamed milk; the other solid, and called butter.

Butter is of a yellow colour, possesses the properties of an oil, and mixes readily with sandy bodies. When heated to the temperature of 96°, it melts, and becomes transparent; if it is kept for some time melted, some curd and water, or whey, separates from it, and it assumes exactly the appearance of oil. But this process deprives it of its great measure of its peculiar flavour.

When butter is kept for a certain time, it becomes rancid, owing to a good measure to the presence of these foreign ingredients; for if butter is well-washed, and a great portion of these matters separated, it does not become rancid nearly so soon as when it is not treated in this manner. It was formerly supposed that this rancidity was owing to the development of a peculiar acid, but Parmenient and Deyerux have shown that no acid is present in rancid butter. When butter is distilled, there comes over water an acid, and an oil, at first fluid, but afterwards concrete. The carbonaceous residuum is but little different.

Butter may be obtained by agitating cream newly taken from milk, or even by agitating milk newly drawn from the cow; but it is usual to allow cream to remain for some time before it is churned, as this lengthens, by standing, acquires a solid taste; butter, therefore, is commonly made from sour cream. Fresh cream requires at least four times as much churning before it yields its butter, as sour cream does; consequently cream acquires, by being kept for some time, new properties, in consequence of which it is more easily converted into butter. When very sour cream is churned, every one who has paid the least attention to these matters has observed, that the buttermilk, after the churning, is not nearly so sour as the cream had been. The butter, in all cases, is perfectly sweet; consequently the acid which had been evolved is a great skin and status dissolved during the process of churning. It has been ascertained, that cream may be churned, and butter obtained, though the contact of atmospheric air should be excluded. On the other hand, it has been affirmed, that when cream is churned in contact with air, it absorbs a considerable quantity of it.

In all cases there is a considerable extinction of gas during the churning of butter.

From the phenomena, it can scarcely be doubted that this gas is carbonic acid. Dr. Young affirms, that during the churning there is an increase of temperature amounting to four degrees.

These facts show that considerable chemical changes go on during the process of churning. The agitation keeps the different substances in contact, and enables them to get upon each other the expulsion of carbonic acid for the diminution of acidity after churning; while the other phenomena would lead us to suppose that the cream, before it becomes butter, united to a new portion of oxygen.

The affinity of the oil of cream for the other ingredients is such, that it never separates completely from them. Not only are curd and whey always found in the cream, but some of this oil is constantly found in creamed milk and whey; for it has been ascertained by actual experiment, that butter may be obtained by churning whey.

Scotch pints of whey yield at an average about a pound of butter. This is, for a fact well known to those who superintend dairies, that a good deal more butter may be obtained from the same quantity of milk, provided it is churned as drawn from the cow, than when the cream alone is collected and churned.

The buttermilk, as Parmenient and Deyerux ascertained by experiment, possesses precisely the properties of milk deprived of cream.

2. Curd, which may be separated from creamed milk by rennet, has many of the properties of coagulated albumen. It is white and solid; and when all the moisture is squeezed out, it has a good deal of brittleness. It is insoluble in water; but pure alkalies and lime dissolve it readily, especially when assisted by heat; and when mixed alkalie is used, a great quantity of ammonia is emitted during the solution. The solution of curd in soda is of a red colour, at least if heat is excited; owing probably to the preparation of charcoal from the curd by the action of the alkalie. Indeed, when a strong heat has been used, charcoal precipitates as the solution cools. The matter dissolved by the fixed alkalie may be separated from the mass of an acid; but it has lost all the properties of curd. It is of a black colour, melts like tallow by the application of heat, leaves oily stains on paper, and never acquires the consistence of curd. Hence it appears that curd, by the action of a fixed alkalie, is decomposed, and converted into two new substances; ammonia, and oil or rather fat.

Curd is soluble also in acids. If over curd newly precipitated from milk, and not dried, there are poured eight parts of water, containing as much of any of the mineral acids as gives it a sensibly acid taste, the whole is dissolved after a little boiling. Acetic acid and lactic acid do not dissolve curd, when very much diluted; but these acids, when concentrated, dissolve it readily, and in considerable quantity. It is remarkable enough, that concentrated vegetable acids dissolve curd readily, but have very little action on it when they are very much diluted; whereas the mineral acids dissolve it when much diluted; but when concentrated, have either very little effect on it, as sulphuric acid, or decompose.
Milk.

it, as nitric acid. By means of this last acid, as Berthollet discovered, a quantity of acetic gas may be obtained from curd.

Curd, as is well known, is used in making cheese and the cheese is the better the more it contains of cream, or of the oil of curd which constitutes cream. It is well known to cheesemakers, that the goodness of it depends in a great measure on the manner of separating the whey from the curd. If the milk is much heated, the coagulum broken in pieces, and the whey forcibly separated, as is the practice in many parts of Scotland, the cheese is scarcely good for anything; but the whey is delicious, especially when the whey last squeezed out, and butter may be obtained from it in considerable quantity. This is a proof that nearly the whole creamy part of the milk has been separated with the whey. Whey is, if the milk is not too much heated (about 100 degrees is sufficient), if the coagulum is allowed to remain unbroken, and the whey separated by very slow and gentle pressure, the cheese is excellent; but the whey is almost transparent, and nearly colourless.

Good cheese melts at a moderate heat; but bad cheese, when heated, dries, curls, and exhibits all the phenomena of burning horn. Hence it is evident, that good cheese contains a quantity of the peculiar oil which constitutes the distinguishing characteristic of cream; whence its flavour and smell.

This resemblance of curd and albumen makes it probable that the coagulation of milk and albumen depends upon the same cause. Heat, indeed, does not coagulate milk, because the curd in it is diluted with too large a quantity of water; but if milk is boiled in contact with air, a pellicle soon forms on its surface, which has the properties of curd. If this pellicle is removed, another succeeds; and by continuing the boiling, the whole of the curdy matter may be separated from milk. When this pellicle is allowed to remain, it falls at last to the bottom of the vessel; where, being exposed to a greater heat, it becomes brown, and communicates to milk that disagreeable taste which, in this country, is called a "stinged" taste. It happens more readily when milk is boiled along with rice, flour, &c.

If to boiling milk there is added as much of any neutral salt as it is capable of dissolving, or of sugar, or of gum arabic, the milk coagulates, and the curd separates. Alcohol also coagulates milk; as do all acids, rennet, and the infusion of the flowers of artichoke and of the thistle. If milk is diluted with ten times its weight of water, it cannot be made to coagulate at all.

3. Whey, after being filtered to separate a quantity of curd which still continues to float through it, is a thin pellicular fluid, of a yellowish-green colour and pleasant sweetish taste, in which the flavour of milk may be distinguished. It always contains a portion of curd; nearly the whole may be separated by keeping the whey for some time boiling; a thick white scum gathers on the surface, which is known by the name of skim-curd. When the liquid, which consists of the curdy part, is carefully separated, the whey, after being allowed to remain at rest for some hours, to give the remainder of the curd time to precipitate, is deanted off as almost colourless as water, and scarcely any of the peculiar taste of milk can be distinguished in it. If it is now slowly evaporated, it deposes at last a number of white-coloured crystals, which are sugar of milk. Towards the end of the evaporation, some crystals of curd and of milk of soda make their appearance. According to Scheele, it contains also a little phosphat of lime, which indeed may be precipitated by ammonia.

After the whey has been obtained from whey, what remains concretes into a jelly on cooling. Hence it follows that whey also contains gelatine. Whey, then, is composed of water, sugar of milk, gelatine, curd, and phosphat of lime. The other salts which are sometimes found in it, are only accidentally present.

If whey is allowed to remain for some time, it becomes sour, owing to the formation of a peculiar acid known by the name of lactic acid. This is to the property of whey that we are to ascribe the acidity which milk contracts for neither curd nor cream, perfectly freed from serum, seems susceptible of acquiring acid properties. Hence the reason also that milk, after it becomes sour, also coagulates. Both ed milk has the property of continuing longer sweet, but it is singular enough that it runs sooner to putrefaction, than ordinary milk.

The acid of milk differs considerably from the acetic; whey, however, may be obtained from milk by a very simple process. If to somewhat more than 8 lbs. of milk six spouls of alcohol are added, and the mixture well corked is exposed to a heat sufficient to support fermentation, provided attention is paid to allow the carbonic acid gas to escape from time to time, the whey, in about a month, will be found converted into vinegar.

Milk is almost the only animal substance which may be made to undergo the vinous fermentation, and to afford a liquor resembling wine or beer, from which alcohol may be separated by distillation. This singular fact seems to have been first discovered by the Tartars, who, by reason of the great quantity of liquors from mare's milk. It has been ascer-

tained, that milk is incapable of being converted into wine till it has become sour; after this nothing is necessary but to place it in the proper temperature, and the fermentation begins of its own accord, and continues till the formation of wine is completed. Scheele had shewed that milk was capable of fermenting; and that a great quantity of carbonic acid gas was extracted from it during this fermentation; but he did not suspect that the result of this fermenta-

tion was the formation of an intoxicating liquor similar to wine: The Tartars call the vinous liquid which they prepare "koomiss.

A very exact account of its preparation and medical uses has been published by Dr. Guth-rie.

When milk is distilled by the heat of a water-bath, there comes over water having the peculiar odour of milk which purifies; and consequently contains, besides mere water, some of the other constituent parts of milk. After some time the milk coagulates, as always happens in hot Alun, and requires a certain degree of concentration. There remains behind a thick mucous yellowish-white substance, to which Hofmann gave the name of fenchiphan. This substance, when the fire is increased, yields at first a tranparent liquid, which becomes gradually more coloured; some very fluid oil comes over, then amnion, an acid, and at last a very thick black oil. Towards the end of the distillation the milk is disengaged. There remains in the retort a coal which contains carbonat of potass, muriat of potass, and phosphat of lime; and sometimes magnesia, iron, and muriat of soda.

Thus we see that cow's milk is composed of the following ingredients:

2. Oil. 7. Muriat of potass.
5. Sugar of milk.

The milk of all other animals, as far as it has hitherto been examined, consists nearly of the same ingredients; but there is a very great difference in their proportion.

Woman's milk has a much sweeter taste than cow's milk. When allowed to remain a long time, a cream gathers on its surface. This cream is more abundant than in cow's milk, and its colour is usually much whiter. After it is separated, the milk is exceedingly thin; and has the appearance of a blueish-white colour, than of cream-milk.

None of the methods by which cow's milk is coagulated succeed in producing the coagulation of woman's milk. It is certain, however, that it contains curd; for if this boiled, particles form on its surface, which have all the properties of curd. Its not coagulating, therefore, must be attributed to the great quantity of water with which the curd is diluted.

Though the cream is churned for a long time, no butter can be obtained from it; but if, after being agitated for some hours, it is allowed to remain at rest for a day or two, it separates into two parts: a fluid which occupies the inferior part of the vessel, pelliculated and of a yellowish colour, and a milk-white translucent fluid which swarms on the surface. The lowermost fluid contains sugar of milk and some curd; the uppermost does not differ from curd, except in consistence. The oily part of the cream, then, would be separated by agitation from the curd. This cream contains a greater portion of curd than the cream of cow's milk.

When this milk, after the curd is separated from it, is slowly evaporated, it yields crystals of sugar of milk and of muriat of soda. The quantity of sugar is rather greater than in cow's milk. According to Halier, the sugar obtained from milk is to that obtained from an equal quantity of woman's milk as 35 to 38, and sometimes as 37 to 67, and in all the intermediate ratios.

Thus it appears that woman's milk differs from that of cow's in three particulars:

It contains a much smaller quantity of curd.

Its oil is so intimately combined with its curd that it does not yield butter. It contains rather more sugar of milk.

Parmentier and Deyeux ascertained, that the quantity of curd in woman's milk increases in proportion to its age after delivery. Nearly the same thing has been observed with respect to cow's milk.
As's milk has a very strong resemblance to human milk. It has nearly the same colour, smell, and consistence. When left at rest for a sufficient time, a cream forms upon its surface, but by no means in such abundance as in woman's milk. This cream, by very long agitation, is converted into butter, which is highly nutritious, of pleasant taste, and fat, and, what is singular, very readily mixes again with the butter milk; but it may be again separated by agitation, while the vessel contains it, is plunged into cold water. Creamed as's milk is thin, and has an agreeable sweetish taste. Alcohol and acids separate it from a little curd, which has but a small degree of consistence. The serum yields sugar of milk, and muriat of lime. As's milk therefore differs from cow's milk in three particulars:

1. Its cream is less abundant and more insipid. It contains less curd. It contains more sugar of milk; the proportion is 35 to 90. Great milk, in consequence of the consistence which is greater, does not differ much from cow's milk. Like that milk it throws up abundance of cream, from which butter is easily obtained. Its milk contains less cow's milk, and yields a greater quantity of curd. Its whey contains sugar of milk, muriat of lime, and muriat of soda.

2. Eve's milk resembles almost precisely that of the cow. Its cream is rather more abundant, and yields a butter which never acquires the consistence of butter from cow's milk. Its curd has a fat and viscid appearance, and is not without difficulty made to assume the consistence of the same, of a kind of cow's milk. It makes excellent cheese.

3. Marc's milk is thinner than that of the cow, but scarcely so thin as human milk. Its cream cannot be converted into butter by agitation. The cream of cow's milk, therefore, makes precisely as of cow's milk, but the curd is not so abundant. The serum contains sugar of milk, sulphate of lime, and muriat of lime.

MILK-WAY, in astronomy, a broad track or path in the heavens, distinguishable by its white appearance; whence it obtains its name. See Astronomy.

MILL, a machine or engine for grinding corn, &c.; or which there are several kinds, according to the various methods of applying the moving power; as water-mills, windmills, &c.

In water-mills the momentum of the water is the moving power; and the attrition of the two stones in grinding is the force to be overcome. Of these there are two kinds, viz., those where the force of the water is applied above the wheel, and those in which it is applied below the wheel; the former being called overhead, and the latter undershot mills; and to these we may add a breast-mill, where the water strikes against the middle of the wheel.

Few people are ignorant that corn is ground by two mill-stones, placed one above the other, without touching. The lower, or rather, mill-stone, is immovable; but the upper one turns upon a spindle. The opposite surfaces of both stones, to grind the corn, are not plane or flat; but the upper one is hollow, and the under ones swell upwards; each of them being of a conic figure, whose axes fades is very short in proportion to the diameter of its base; for the upper one, being six feet in diameter, is hollowed but about one inch at its centre; and the lower one rises but about three-fourths of an inch. These two mill-stones come nearer and nearer towards their circumferences, whereby the corn that falls from the hopper has room to incise between them as far as two-thirds of the radius, which is the place of the breakage, where it is impossible for the stone to make the greatest resistance that it is capable of; the space between the stones being in that place but about two-thirds or three-fourths of the thickness of a grain of corn. But as the mill-stones will not be raised or sinking the upper stone a little, they can proportion its distance from the lower one, according as they would have the floor finer or coarser.

The circular motion of the upper mill-stone brings the corn out of the hopper by jerks, and causes it to recede from the centre towards the circumference; where being quite reduced to flour, it is thrown out of the milling, and there must be a hole provided for purpose.

As the water acts upon an overshot-mill both by impulsion and weight, so does it act upon a breast-mill, or that where the water contains the full weight of the body of water; and here, though the weight of the water is not so great as in the overshot mill, being contained in the buckets of the lower quarters: yet the impulse of the water is much greater, the height of the water being increased nearly the semidiameter of the great wheel, all other things being equal. If the height of the water remains the same, the aperture of the penstock, or flood-mate, must be enlarged twice or three times the area, that the force may be the same; so that to produce the same effect, twice as much water is necessary for a breast-mill as for an overshot one, every thing else being the same.

As to the undershot-mill, it is evident that there can be only the impulsion from the water; and therefore the height of the water remains the same, the aperture of the penstock, or flood-mate, whence a greater area of water is expended in it than in any other mill, and can only be supplied for a constancy by a river; and where this can be had, the undershot is the easiest, cheapest, and most simple structure a mill is capable of.

Mr. Smeaton has considered the best methods of constructing all these mills from machines and models made on purpose; but, conclusions of the inferiority of models to actual practice, and that it is to give his opinion without having seen them actually tried, and the truth of his doctrines established by practice.

Having described the machine and models used for making his experiments, he observes, that, with regard to power, it is most properly measured by the raising of a weight; or, in other words, if the weight raised is multiplied by the height to which it can be raised, we have the greatest positive effect or impact of the power raising it; and, of consequence, all those powers are equal whose products made by such multiplication are equal; for if a power can raise twice the weight to the same height, or the same weight twice the height, in the same time that another can, the former power will be double the latter; but if it raises irrationally twice half the weight to double the height, or double the weight to half the height, in the same time that another can, the two powers are equal. This, however, must be understood only of an insensible change; for if a power could raise an object or retard it by alternation or retardation, that the velocity is either very quickly accelerated or retarded, the vis inerar, in our author's opinion, will produce an irregularity.

To compute the effect of water-wheels exactly, it is necessary to know, in the first place, what is the real velocity of the water which impinges on the wheel: 2. The quantity of water expended in a given time; and, 3. How much of the power is lost by the friction of the machinery.

1. With regard to the velocity of the water, Mr. Smeaton determined by experiments with machinery, that with a head of water 15 inches in height, the velocity of the wheel is 8.960 feet in a minute. The area of the head being 10 square inches, this multiplied by the weight of a cubic inch of water, equal 16.379 of an ounce avoirdupois, gives 61.26 ounces for the weight of as much water as is contained in the head upon one inch in depth; and by further calculations, the machinery made use of, in computing that 204.7 pounds of water descend in a minute through the space of 15 inches. The power of the water, therefore, to produce mechanical effects in this case, will be 204.7 x 13, or 2670. From the result of the experiment, however, it appeared that a vast quantity of the power was lost; the effect being only to raise 9.375 pounds to the height of 135 inches; so that the power was to the effect as 3770 to 0.375 x 133 = 1260, or as 10 to 3.18

This, according to Mr. Smeaton, must be considered as the greatest single effect of water upon an undershot-wheel, where the water descends from a height of 15 inches; but as the force of the current is not by any means exhausted, we must consider the true proportion between the power and effect to be that between the quantity of water already mentioned, and the sum of all the effects of that current. This remainder of power, it is plain, must be equal to that of the velocity of the wheel itself multiplied into the weight of the water. In the present experiment, the circumference of the wheel moved with a velocity of 3.123 feet in a second, which answers to a head of 1.822 inches; and this height being multiplied by 204.7, the quantity of water expended in a minute, gives 481 for the power of the water; after it has passed the wheel, and hence the true proportion between the power and the effect will be as 3849 to 1260; or as 11 to 4.

As the wheel revolved 86 times in a minute, the velocity of the water must be equal to 86 circulations of the wheel; which, according to the dimensions of the apparatus used by Mr. Smeaton, was as 86 to 30, or as 20 to 7. The greatest load with which the wheel would move was .9 lb. 6 oz. and by 12 lb. it was entirely stopped; but accelerating, that the author concludes, that the impulse of the water is more than double of what ought to be according to theory; but this he accounts for by supposing, that in his experiment the wheel was placed not vertically, as in the natural current, after it has communicated.
its impulse to the float, has room on all sides to escape, as the theory supposes, but in a conical form, to which the float being adapted, the water cannot otherwise escape but by moving along with the wheel. It is observable, that a wheel working in this manner, as soon as it begins to turn, and the water, receiving a sudden check, rises up against the float like a wave against a fixed object; insomuch that, when the sheet of water is not a quarter of an inch thick before the float, yet this sheet will not act upon the whole surface of the float whose height is three inches; and, consequently, was the float no higher than the thickness of the sheet of water, as the theory also supposes, a great part of the force would have been lost by masking the float.

Mr. Smeston next proceeds to give tables of the velocities of wheels with different heights of water; and from these deduces the following conclusions: 1. The velocity produced by the water in the same time, will nearly be as the quantity of water expended. 2. The expence of water being the same, the effect will be nearly as the height of the virtual, or effective head. 3. The expence of water expended being the same, the effect is nearly as the square of the velocity. 4. The aperture being the same, the effect will be nearly as the cube of the velocity of the water. Hence, if water passes over a wheel, the expence being the same, but with different velocities, the expence will be proportional to the velocity; and therefore, if the expence is not proportional to the velocity, the section of the aperture is not the same. The virtual head, that from which we are to calculate the power, bears no proportion to the head-water; but when the aperture is larger, the power of the water is nearer to a coincidence; and consequently, in the large openings of mills and machinery, where great quantities of water are discharged from moderate heads, the head of water, and virtual head determined from the velocity, will nearly agree: which is also confirmed by experience.

6. The most general proportion between the power and expence is that of 10 to 3; the extremes 10 to 2, and 10 to 2.5. But it is to be considered, where the power is greatest, the second term of the ratio is greatest also; hence we may allow the proportion subsisting in great works to be as three to one. 7. The proportion of velocity between the water and wheel is, in general, about five to two. 8. There is no certain ratio between the load that the wheel will carry at its proper maximum, and what will totally stop it; though the proportions are contained within the limits of 20 to 19, and 20 to 15: but as the effect approaches nearest to the ratio of 20 to 15, of 4 to 3, when the power is greatest, either by increase of velocity, or quantity of water, this seems to be the most applicable to large works; but as the load that a wheel ought to have, in order to work to the best advantage, can be assigned by knowing the effect that it ought to produce, and the velocity it ought to have in producing it, the exact knowledge of the greatest load it will bear is of the least consequence in practice.

Mr. Smeston, after having finished his experiments on the undershot-mills, reduced the number of floats, which were originally 24, to 12; which caused a diminution in the effect, by reason that a greater quantity of water escaped between the floats and the floor than before; hence, in order to keep the original impulse, the remainder being spent in changing their figure in consequence of the stroke. The ultimate conclusion is, that the effects as well as the powers are as the quantities of water and perpendicular heights multiplied together respectively.

2. By increasing the head, it does not appear that the effects are at all augmented in proportion; for, by raising it from 3 to 11 inches, the effect was augmented by less than one-seventh of the increase of perpendicular height. Hence it follows, that the higher the wheel is in proportion to the whole descent, the greater will be the effect; because it diminishes less upon the impulse of the head, and more upon the gravity of the water in the buckets: and if we consider how obliquely the water issuing from the head must strike the buckets, we shall not be at a loss to account for the same solid advantage that arises from the impulse thereof, and shall immediately see of how little consequence this is to the effect of an overshot-wheel. This, however, as well as other things, must be subject to improve the writer's conclusions, in the theory of the water should be somewhat greater than the wheel, otherwise the latter will not only be retarded by the striking of the buckets against the water, but some of the power will also be lost in the dashing of the water over the buckets.

3. To determine the velocity which the circumference of the wheel ought to have, in order to produce the greatest effect, Mr. Smeston observes, that the more slowly any body descends by the force of gravity, when acting upon any piece of machinery, the more that force will be spent upon it; and consequently the effect will be greater. If a stream of water falls into the bucket of an overshot-wheel, it will be there retained till the wheel discharges it by moving round; and of consequence, the slower the wheel moves, the more water will it receive: so that what is lost in velocity, with the greater pressure of water upon the buckets. From the experiments, however, it appears, that when the wheel made about 20 turns in a minute, the effect was the greatest; when it made only 18 it was very faulty, and when loaded so as not to admit its turning 18 times, the wheel was overloaded with the load. When it made 30 turns, the power was diminished more than a twentieth; and when the number of turns was increased to 40, it was diminished by one-fourth. Hence we see, that in practice, the velocity of the wheel should not be diminished farther than what can be done by raising the point of power; because, ceteris paribus, the buckets must be larger as the motion is slower; and the wheel being more loaded with water, the stress will be proportionately increased upon every part of it. Moreover, this velocity is necessary for practice, therefore, will be that when the wheel makes 30 turns in a minute, which is little more than three feet in a second. This velocity is applicable to the highest overshot-wheels as well as the lowest. Experience however determines, that high wheels may deviate farther from this rule before they will lose their power by a given aliquot part of the whole, than low ones can be permitted to do; for a wheel of 24 feet high may move at
the rate of six feet per second, while our author states one of them to be steady and well win a velocity of little more than two feet. The reason of this superior velocity in the 24-feet wheel, may probably be owing to the small proportion that the overhead wheel bears to the whole height.

4. The maximum load for an overshot-wheel is that which reduces the circumference of the wheel to its proper velocity; which is known by dividing the effect it ought to produce in a given time, by the space intended to be described by the circumference of the wheel in the same time: the quotient will be the resistance overcome at the circumference of the wheel, and is equal to the load required, including the friction and resistance of the machinery.

5. The greatest velocity that an overshot-wheel is capable of, depends jointly upon the diameter, or height of the wheel, and the velocity of falling bodies; far it is plain that the velocity of the circumference can never be greater than to describe a semicircumference, while a body let fall from the top describes the same in the same time. The difference in point of time must always be in favor of that which falls through the diameter. Thus, suppose the diameter of the wheel to be 10 feet and an inch in diameter, a heavy body would fall through this space in one second; but such a wheel could never arrive at this velocity, or make one turn in two seconds, nor could an overshot-wheel ever come near it, because, after it has acquired a certain velocity, and from the force of the water is prevented from entering the buckets, and part is thrown out again by the centrifugal force; and as these circumstances have a considerable dependence upon the form of the buckets, it is impossible to lay down any general rule for the velocity of this kind of wheels.

6. Though in theory we may suppose a wheel to be made capable of overcoming any resistance whatever, yet, as in practice, it is known by experience, that the wheel and buckets of some certain and determinate size, we always find that the wheel will be stopped by such a weight as is equal to the effort of the water in all the buckets of a semicircumference once put into action, by the force of the water, from the structure of the buckets themselves; but, in practice, an overshot-wheel becomes unserviceable long before this; for when it meets with such an obstacle as diminishes its velocity to a certain degree its motion becomes irregular; but this never happens till the velocity of the circumference is less than the two feet per second, when the resistance is equal.

7. From the above observations we may easily deduce the force of water upon breast-wheels, &c. But, in general, all kinds of wheels where the water cannot descend through a given space unless the wheel moves with it, are to be considered as overshot-wheels; and those which receive the impulse or shock of the water, whether in a horizontal, oblique, or perpendicular direction, are to be considered as undershot. Hence in a wheel in which the water strikes at the top point below the surface of the head, and after that descends in the arch of a circle, pressing by its gravity upon the wheel, the effect of such a wheel will be equal to that of an undershot whose head is equal to the difference of level between the surface of the water in the receiver and where it strikes the wheel, added to that of an overshot whose height is equal to the difference of level between the point where it strikes the wheel and the level of the tail-water.

We shall require these transactions for our author considers some of the causes which have produced dislocations and disputes among mathematicians upon this subject. He observes, that soon after Sir Isaac Newton had discovered, that "the quantity of motion is the measure of the same, arising from the velocity and quantity of matter conjointly," it was controverted by his contemporary philosophers. They maintained, that the measure of the quantity of motion should be estimated by taking the quantity of matter and the square of the velocity conjointly. On this subject he remarks, that from equal impelling powers acting for equal intervals of time, equal augmentations of velocity are acquired by bodies when they are not resisted by a medium. Thus a body descending one second by the force of gravity, passes through a diameter in one second. After the end of that time it has acquired a velocity of 32 ft. 2 inc. in a second: at the end of 2 sec. it has acquired one that would carry it through 64 ft. 4 inches in a second. If, therefore, in consequence of this equal increase of velocity, we define this to be a double quantity of motion generated in a given time in a certain quantity of matter, we come near to sir Isaac's definition: but in trying experiments with the bodies of matter. It appears, that when a body is put in motion, by whatever cause, the impression it will make upon a uniformly resistless medium, or upon uniformly yielding substances, will be as the mass of matter of the moving body multiplied by the square of its velocity. The question therefore properly is, whether those terms, the quantity of motion, the momentum, or forces of bodies in motion, are to be conceived to be such quantities, when they have been generated by an equal impulse acting for an equal, double, or triple time? or that it should be measured by the effects being equal, double, or triple, in overcoming a certain space, or being able to stop? For, according to the meaning we put upon these words, the momenta of equal bodies will be as the velocities or squares of the velocities of the moving bodies.

Though by a proper attention to the terms employed, however, we shall find both these doctrines to be true; it is certain that some of the most celebrated writers upon mechanics have fallen into errors by neglecting to attend to the meaning of the terms they make use of. Desaguliers, for instance, after having been at pains to show that the dispute, which in his time had subsisted for 30 years, was a dispute merely about words, tells us, that both opinions may be easily reconciled in the following case, viz. that the wheel of an undershot water-wheel is capable of doing quadruple work when the velocity of the water is doubled, instead of double work only; on the contrary, admitting the same, we find, that as the water's velocity is doubled, there are twice the number of particles that issue out, and therefore the ladle-board is struck by twice the matter; which matter moving with twice the velocity that it had in the first case, the whole effect must be quadruple, though the instantaneous stroke of each particle is increased in the last proportion of the velocity." In another place the same author tells us, that though the knowledge of the foregoing particulars is absolutely necessary for setting an undershot-wheel to work, yet the advantage to be required from it would still be guess-work, and we should at a loss to find out the utmost that it could perform, had it not been for an ingenious proposition of that excellent mechanic, M. Parenst, of the royal academy of sciences, who has shewed, that an undershot-wheel can do the most work when its velocity is equal to the third part of that of the water; because then two-thirds of the water are employed in driving that part of the force proportional to the square of the velocity. By multiplying the surface of the adjutage or opening by the height of the water, we shall have the column of water that moves the wheel. The wheel then moved will consist of two sides only four-ninths of that weight which will keep it in equilibrium; but what it can move with the velocity it has, is only one-ninth of the equilibrium. This conclusion is likewise adopted by Mr. M. Hov.

Mr. Snaeton, in the year 1759, instituted another set of experiments; the immediate object of which was, to determine what proportion or quantity of mechanical power is expended in giving the same degree of motion, or in producing the same degree of velocity. Having constructed a proper apparatus for the purpose, and with it made a number of experiments, he concludes, that "power, properly speaking, has nothing to do with the production of mechanical effects, otherwise than as by equally flowing it becomes a common measure; so that, whatever mechanical effect is found to be produced in a given time, is always the same, and is independent of the whole power employed, if the same quantity of corn is in an hour: but, supposing the mill to be capable of receiving a greater impulse with as great advantage as is less; then, if the corn is let out twice as fast, the same quantity of corn will be ground in half an hour, the whole of the water being likewise expended in that time. What time has therefore to do in the case is this: Let the rate of division be supposed to be the effect, be what it will; if this rate is uniform, when I have found by experiment what is done in a given time, then, proceeding at the same rate, twice the effect will be produced in twice the time; on supposing that the supply of mechanical power to go on with. Thus, 1000 tons of water descending through 20 feet perpendicular, being, as has been shewn, a given mechanical power, let it be expended in three minutes; then, if this power, being continued, we are to wait another hour till an equal quantity can be procured, then we can only expend 12 such quantities in 24 hours." But if, while the thousand tons of water are expending in one hour, the same quantity is
renewed, we can then expend 24 such in the 24 hours, or go on without intermission. The product or effect will then be in proportion to time, which is the common measure; but the quantity of mechanic power arising from the flow of the two rivers, compared by taking the work done in any one, is equal to that done one to the other; though each has a mill-that, when going, will grind an equal quantity of corn in an hour.\footnote{The following is a description of a common mill of the most common sort. See Plate, Mills.}

A & B (fig. 1) is the water-wheeler, which is generally from 18 to 24 feet in diameter, reckoned from the outermost edge of any flint-board at A, to that of the opposite one at B. The water striking on the floats of this wheel drives it round, and gives motion to the mill. The wheel is fixed upon a very strong axis or shaft, C, one end of which rests on D, and the other on E, within the mill-house.

On this shaft, or axis, and within the mill-house, is a wheel F, about eight or nine feet in diameter, having cogs all round, which work in with the float-board when the wheel is turned to E. This trunche is fixed upon a strong iron axis, called the spindle, the lower end of which turns in a brass foot fixed at H, in a horizontal beam I, called the bridge-tree; and the upper end of the spindle turns in a wooden bush fixed into the nether mill-stone, which lies upon beams in the floor I. The top of the spindle above the bush is square, and goes into a square hole in a strong iron cross-head, (fig. 2,) called the rynd; under which, and close to the bush, is a round piece of thick leather upon the spindle, which it turns round at the same time as it does the rynd.

The rynd is let into grooves in the upper surface of the running mill-stone K, and so turns it round in the same time that the trunche G is turned round by the cog-wheel F. This mill-stone has a large hole quite through its midst, and, like that of the stone, through which the middle part of the rynd and upper end of the spindle may be seen; whilst the four ends of the rynd lie below the stone in their grooves.

One end of the bridge-tree, which supports the spindle, rests upon the wall, whilst the other is let into a beam, called the brayer, LM.

The brayer rests in a mortice at L; and the other end M hangs by a strong iron rod N, which goes through the floor I, and has a screw-nut on its top at O; by the turning of which nut, the end M of the brayer is raised or depressed at pleasure; and consequently the bridge-tree and the upper mill-stone. By this means the upper mill-stone may be set as close to the lower one, or raised as high from it, as the miller pleases.

The nearer the mill-stones are to each other, the finer the corn is ground; and the more remote from one another, the coarser.

The upper mill-stone is inclosed in a round box, which does not touch it anywhere, and is about an inch distant from its edge all round. On the top of this box stands a frame for holding the hopper P, to which is hung the shoe Q, by two lines fastened to the hinder part of it, fixed upon hooks in the hopper, and by one end of the string R fastened to the fore part of it; the other end being twisted round the pin S. As the pin is turned one way, the string draws up the shoe closer to the hopper, and so lessens the aperture between them; and as the pin is turned the other way, it lets down the shoe, and enlarges the aperture.

If the shoe is drawn up quite to the hopper, no corn can fall from the hopper into the mill: if it is let down a little, some will fall; and the quantity will be more or less, according as the shoe is more or less let down; for the hole in the bottom of the shoe, not directly under the bottom of the hopper, but nearer to the lowest end of the shoe, over the middle eye of the mill-stone.

There is a square hole in the top of the spindle, in which is put the feeder F (fig. 2); this feeder, as the spindle turns round, jogs the shoe three times in each revolution, and so causes the corn to run constantly down from the hopper through the shoe into the eye of the stone where it falls upon the top of the rynd, and is, by the motion of the rynd, and the leather under it, thrown down the upper stone, and ground between it and the lower one. The violent motion of the stone creates force in stone, as it is going round with it, by which means it gets farther and farther from the stone, as in a spiral, in every revolution, until it is quite thrown out; and being then ground, it falls through the middle eye of the mill-stone, into a trough placed to receive it.

When the mill is fed too fast the corn bears up the stone, and is ground too coarse; and, besides, it clogs the mill, so as to make it go too slow. When the mill is too slowly fed, it goes too fast; and the stones, by their attrition, are apt to strike fire. Both these inconveniences are avoided by turning the pin S backward or forward, which draws up or lets down the shoe; and then regulates the feeding, as the miller sees convenient.

The heavier the running mill-stone is, and the greater the quantity of water that falls upon the wheel, the faster will the mill bear to be fed, and consequently it will grind the more: and, on the contrary, the lighter the stone, and the less the quantity of water, the slower the miller must feed it. But when the stone is considerably worn, and become light, the mill must be fed slowly at any rate; otherwise the stone will be too much borne up by the corn under it, which will make the meal coarse.

The quantity of power sufficient to turn a heavy mill-stone, is but very little more than what is necessary to turn a light one; for as the latter is supported upon the spindle by the bridge-tree, and the end of the spindle that turns in the brass foot therein being but small, the difference arising from the weight is but very inconsiderable in its action against the power or force of the wheel and, besides, a large stone has the same advantage as a heavy lye, namely, that it regulates the motion much better than a light one.

The centrifugal force carrying the corn towards the circumference of the stone, is natural it should be crushed, when it comes to a place where the interval between the two mill-stones is less than its thickness; yet the upper mill-stone being supported on a point which it can never quit, it does not so clearly appear why it should produce a greater effect when it is heavier than when it is lighter; since, if it were equally distant from the nether mill-stone, it could only be capable of a limited impression. But as experience proves that this is really the case, it is necessary to discover the reason. The reason is, that the upper stone being supported by a horizontal piece of timber, about nine or ten feet long, resting only on both ends, by the elasticity of this piece, the upper mill-stone is allowed a vertical motion, playing up and down; by which movement, the heavier the stones are, the more forcibly is the corn wedged in between them.

In order to cut and grind the corn, both the upper and under mill-stones have channels or furrows cut into them, proceeding obliquely from the centre to the circumference. And these furrows are cut perpendicularly on one side, and obliquely on the other, which gives each furrow a sharp edge; and in the two stones they come against one another, like the edges of a pair of scissors; and so cut the corn, to make it grind the easier, when it falls upon the places between the furrows. These are cut the same way in both stones, but so as to make them run crossways to each other when the upper stone is invected, by turning its furrowed surface towards that of the lower; so as the furrows of both stones lay the same way, a great deal of the corn would be driven over in the lower furrows, and so come out from between the stones, without being either cut or bruised.

The grinding surface of the under stone is a great concave, cut so as to be edge to the centre, and that of the upper stone a little concave, so that they are farthest from one another in the middle, and approach gradually nearer towards the edges. By this means the corn, at its first entrance between the stones, is only bruised; but as it goes farther on towards the circumference or edge, it is cut smaller and smaller; and, at last, finely ground, just before it comes out from between the stones.

When the furrows become blunt and shallow by wearing, the running-stone must be taken up, and both stones new dressed with a chisel and hammer; and every time the face of the stone is worked over, the same allowance is made in the upper stone, so that when round the spindle upon the bush, which will soon be melted by the heat, the spindle acquires from its turning and rubbing against the bush, and so will get in betwixt then; otherwise the bush would take fire in a very little time.

The bush must embrace the spindle quite close, to prevent any shake in the motion, which would make some parts of the stones grate upon others, whilst the other parts of them would be too far asunder, and by that means spoil the meal.

Whenever the spindle wears the bush, so as to begin to shake in it, the stone must be taken up, and a chisel driven into several parts of the bush; and when it is taken out, wooden wedges must be forced into the holes; by which means the bush will be made to embrace the spindle again, close round. In order to drive these wedges into the bush on opposite sides of the spindle; otherwise it will be thrown out of the perpendicular, and so hinder the upper stone from being set parallel to the under one, which is absolutely necessary for
making good work. When any accident of this kind happens, the perpendicular position of the spindle must be restored, by adjusting the bridge-true with proper wedges put between it and the beam.

It often happens that the yund is a little wrinkled in laying down the upper stone upon it, or is made to sink a little lower on one side of the spindle than on the other; and this will cause one edge of the upper stone to drag all round upon the other, while the opposite edge will not touch. But this is easily set to rights, by raising the stone a little with the lever, and putting bits of paper, cards, or thin chips, between the yund and the stone.

A less quantity of water will turn an undershot-mill (where the wheel has buckets instead of float-boards) than a breast-mill, where the fall of water seldom exceeds half the height of the wheel; so that there is but a small quantity of water, and a fall great enough for the wheel to lie under it, the bucket, or overshot-wheel, is always used: but there is a great difference in the speed of the water under a little fall, the breast, or float-board, wheel must be used. Where the water runs only upon a small declivity, it can act but slowly upon the under part of the wheel; in which case the motion of the wheel will be slow, and therefore the floats ought to be very long, though not high, that a large body of water may act upon them; so that what is wanting in velocity may be made up in power; and then the cog-wheel may have a greater number of cogs, in proportion to the rounds in the trundle, in order to give the mill-stone a sufficient degree of velocity.

It was the opinion of Sneaton, that the powers necessary to produce the same effect on an undershot-wheel, a breast-wheel, and an overshot-wheel, must be to each other as the numbers 2, 1.75, and 1.

Practical rules for the construction of mills. — 1. Measure the perpendicular height of the fall of water, in feet, above that part of the wheel on which the water begins to act, and call that the height of the fall.

2. Multiply this constant number 64.2892 by the height of the wheel, and the root of the product will be the velocity of the water at the bottom of the fall, or the number of feet that the water there moves per second.

3. Divide the velocity of the water by three, and the quotient will be the velocity of the float-boards of the wheel, or the number of feet they must each go through in a second, when the water acts upon them so as to have the greatest power to turn the mill.

4. Divide the circumference of the wheel in feet by the velocity of its floats in feet per second, and the quotient will be the number of seconds in which the wheel turns round.

5. By this last number of seconds divide 60, and the quotient will be the number of turns of the wheel in a minute.

6. Divide 120 (the number of revolutions a mill-stone four feet and a half diameter ought to have in a minute) by the number of turns of the wheel in a minute, and the quotient will be the number of turns the mill-stone ought to have for one turn of the wheel.

Then, as the number of turns of the wheel in a minute, is to the number of turns of the mill-stone in a minute, so must the number of stones in the trundle, be to the number of cogs in the wheel, in the nearest whole numbers that can be found.

By these rules the following table is calculated to a water-wheel 18 feet diameter, which may be a good size in general.

The Mill-Wright's Table.

</table>

To construct a mill by this table, find the height of the fall of water in the first column, and against that height, in the sixth column, you have the number of cogs in the wheel, and staves in the trundle, for causing the mill-stone, four feet six inches diameter, to make about 190 revolutions in a minute, as near as possible, when the wheel goes with one-third part of the velocity of the water. And it appears by the 7th column, that the number of cogs in the wheel, and staves in the trundle, are so near the truth for the required purpose, that the number of revolutions of the mill-stone in a minute is 118, and the greatest number never exceeds 121; which is according to the speed of some of the best mills.

One of the most usual communications of motion in machinery, is by means of toothed wheels acting on each other. It is of the greatest consequence to have the teeth so formed, that the pressure by which one of them urges the other round its axis is constantly the same. This is by no means the case when the common construction of a spur-wheel, acting in the cylindrical staves of a lathe, or trundle, is used. The ends of teeth should never be formed of parts of circles, but of a particular curve, called the epicycloid, which is formed by moving the circle, called the generating circle, round the circumference of another circle, while it cuts the inner or under sides of the teeth may be of any form, yet it is better to make both sides alike, which will serve to make the wheel turn backwards. The more teeth that work together the better; at least one tooth should always begin before the other has done working. The teeth ought to be disposed as not to trouble or hinder one another before they begin to work.

If the cogs of a wheel and rounds of a trundle could be put in as exactly as the teeth are cut in the wheel and pinnings of a rack, then the trundle might divide the wheel exactly, that is to say, the trundle might make a given number of revolutions for one of the wheel, or their fraction. But as any exact number is not necessary in mill-work, the cogs and rounds cannot be set in so truly as to make all the intervals between them equal, a skilful mill-wright will always give the wheel what he calls a hunting-cog; that is, one more than what will answer to an exact division of the wheel by the trundle. And then as every cog comes to the trundle, it will take the next staff, or round, behind the one which it took in the former revolution; and by that means will wear all the parts of the cog, and rounds which work upon one another equally, and to equal distances from one another, in a little time. See Flour-Mill.

Mills, BARK, like most other mills, are worked sometimes by means of horses, at others by water, and at others by wind. One of the best mills we have seen described for this purpose is that invented by Mr. Bag- 

wells, of Worcestershire; this machine will serve not only to grind, to riddle, and pound it, but to beam, or work green hides and skins out of the master- ing, or drench, and make them ready for the ome, or bark-barrow; to beam sleeperskins and other skins for the Skinner's use, and to scour and take off the bloom from tanned
leather, when in the currying state. The nature and connection of the different parts of this contrivance may be understood from the figures and following description:

Fig. 3 is a horizontal plan of the mill. Fig. 4, a vertical section of it. Fig. 5, a transverse section of it.

A, the water-wheel, by which the whole mechanism is worked.
B, the shafts.
C, the spur-wheel, which is fixed on the water-wheel shaft B, and turns the upright shaft E, by the wheel F, and works the cutters and hammer by taps.
D, the spur and bevel-wheel at the top of the large upright shaft E.
E, the upright shaft.
F, the crown-wheel, which works in the pit-wheel G.
G, the spur-wheel or the stone I.
H, the hammer, to crush or bruise the bark that falls into the dish S, which said dish is on the incline, so that the hammer keeps forcing it out of the lower side of the said dish when bruised.
K, the wheel, to receive the dust and moss that passes through the trial Q.
L, the bevel-wheel, which works in the wheel D, which works the beam-knife by a crank V, at the end of the shaft n.
M, the pinion or pin-wheel, which leads from the crank V to the start x.
N, the start, which has several holes in it to lengthen or shorten the stroke of the beam-knife.
O, the shaft, to which the slide-rod k, h, are fixed by the start n.
P, the slide-rod, on which the knife f is fixed; which knife is to work the hides, &c.
Q, the trial that receives the bark from the cutters, and conveys it into the hopper H, by which it descends through the shoe to the stone I, where it is ground.
R, the spur-wheel, which receives the bark from the stone I, and conveys it into the trial L, which trial is used to sift or dress the bark, as it descends from the stone I.
S, the mout, through which to receive the bark that passes through the trial L. It is not necessary to describe the other parts of this machine, which are to be understood from the annexed drawing. The principal parts of the mechanism which relates to the turning of the sides of the bark are fixed on the axis, and the long axis of the mill.

The bark, after it has been cut by the knife f, is conveyed by the beam-knife B, into the hopper H, thence conveyed by the upright shaft E, and turned by the beam-knife B, and the hammer C, and the crown-wheel F, which works on the pit-wheel G, and works with the upright shaft E, and works with the upright shaft E, and the water-wheel A, which is turned by the water-wheel A.

The beam P, with knives or cutters, may either be worked by tappers, as described, or by the bevel-wheel B, with a crank, as V, to cut the same as shears.

The knife f is fixed at the bottom of the start, which is fixed on the slide-rod k; the bottom of the start is split open to admit the knife f, which should have a gudgeon at each end, to fix it in the open part of the start; and the two springs a, a, prevent the knife from giving too much play in this way when working; the knife should be one foot long, and from five to seven inches broad.

The arch-head e will shift nearer to, or farther from, the beam b, and will be fixed so as to carry the knife back as far as is wanted, or it may be taken away till wanted.

The trials k, for use in placing the knife at the handle m, which takes up the slide-rod so high as to give head-room under the beam-knife. The handle may be hung up with a wheel to turn it in the required direction, or to be turned by hand to turn it up or down. The wheel will turn it up or down, and the handle may be turned in either direction.

The handle may be hung up with a wheel to turn it in the required direction, or to be turned by hand to turn it up or down. The wheel will turn it up or down, and the handle may be turned in either direction.
feet while his fore feet will be at rest; and further, the motive force being applied near the vertex of the wheel will act with but little advantage, and the work done will be comparatively trifling.

Hand – Mill, or horse-mill, is that worked by the hand, or by horses, &c. There is a long beam or lever for moving it, so attached that it may receive many men or horses, to drive several mills at once. There is the cog-wheel, placed horizontally, with pins fixed, not on its plane, but on the outside, at the circumference of the joints. There are also the trundle-head, the support, the iron rails, and the drum where the mill-stones are inclosed.

MILLENIARIES, or CHILLASTS, a name given to those who, in the primitive ages, believed that the saints will one day reign on earth with Jesus Christ a thousand years.

MILLEPES. See OSICUS.

MILLEPORA. See MADRASPORA, ZOO-PHITAE, and Plate Nat. Hist. figs. 266, 267.

MILLERIA, a genus of the syngeosis polygamaeian class of plants, the compound flower of which is radiated; there is scarcely any visible receptacle of the seeds, which are scattered after each particular flower, and have no pappus or down. There are three species.

MILLET. See MILLUM, and PANCUM.

MILLET-GRASS. See MILIUM.

MILLING. See FOLLING.

MIMOSA, the sensitive plant, a genus of the polygama order, in the monocot class of plants, and in the natural method ranking under the 33d order, lomentaceae. The herbaceous calyx is quinquedentate; the corolla quinquelat; there are five or more stamens, one pistil, and a legumen; the male calyx is quinquedentate; the corolla quinquelat, with five, ten, or more stamens.

The name mimosa signifies "tender," and is given to this genus, from the sensitiveness of the leaves, which, by their motion, mimic or imitate the motion of animals. This genus comprises 83 different species, all natives of warm climates. Of the species cultivated here in our gardens, &c. some are of the shrub and tree kind, and two or three are herbaceous perennials and annuals. The sensitive kinds are exceedingly curious plants in the very singular circumstance of their leaves receding rapidly from the touch, and running up close together; and in some sorts the foot-talks and all are affected, so as instantly to fall downward as if fastened by hinges, which last are called humire sensitive. They have all winged leaves, each wing consisting of many small pinnae.

The following are the most remarkable:

1. The sensitive, or common sensitive humire plant, rises with an under-shrub pricky stem, branching six or eight feet high, armed with crooked spines; conjugated, pinnated leaves, with bigjugated partial lobes or wings, having the inner ones the least, each leaf on a long footstalk; and at the sides and ends of the branches many purple flowers in roundish heads; succeed by broad, flat, jointed pods, in radiated clusters. This is somewhat of the humble sensitive kind; the leaves, footstalks and all, receding from the touch, though not with such facility as in some of the following sorts.

2. The pudica, or bashful humire plant, rises with an under-shrubby, pricked stem, branching two or three feet round, armed with hairy spines. This is truly of the humble sensitive kind; but for the leaves to touch the leaves instantly recede, contract, close, and, together with the footstalk, quickly decline downward, as if ashamed at the approach of the hand.

3. The perambuca, or perambuca slothful mimosa, recedes very slowly from the touch; it has only a little, when smartly touched: hence the name slothful mimosa.

4. The asperata, or Panama sensitive plant, seldom rises above three feet in height; but it has a stem, the leaves of which are so sensitive that it will recede, when touched, upon the neighbouring bushes. It is armed with crooked sharp spines, so thickly set on the trunk, branches, and leaves, that there is no touching it with safety. But the plant has a most singular appearance; it is covered with long and globular, growing at the extremity of the branches. The pods are hairy, brown, and jointed; each containing a small, flat, and brown seed. The leaves are numerous, small, and rounded, and the mimosa princi- dica they are the most irritable; contracting with the least touch, and remaining so for several minutes after. This species would form a good hedge or fence round a garden.

The punctuated sensitive mimosa, rises with a shrubby, upright, taper, spotted, unarm ed stem, branching erectly five or six feet high; bipinnated leaves, of five or five pair of long winged foli oles, having each about 20 pair of pins e; and at the axillias and termination of the branches oblong spikes of yellowish decandrous flowers, the inferior ones castrated; succeeded above by oblong pod-pods. This species is naturally on the shrubby and perennial in its native soil, yet in this country sometimes decays in winter. It is only sensitive in the foliolas, but quick in the motion.

5. The saya, lively mimosa, or smallest sensitive weed, has many creeping roots, and spreads itself so as to cover large spots of ground. It rises at most to two inches, and has winged leaves, with numerous small pinnas. The fruits are characteristic of the mimosa colour, and grows in clusters from the axille: these are followed by little, short, hairy pods, containing smooth shining seeds. This is the most sensible of all the mimosas, the pudica not excepted. By running a stick over the plant, a person may write his name, and it will remain visible for ten minutes.

6. The quadrivalvis, perennial, or quadrivalve humire mimosa, has herbaceous, slender, quadrangular, prickly twigs or branches, spreading all around, armed with recurved spines; bipinnated leaves of two or three pair of winged lobes, having each many pins e; and at the axillias globular heads of purple flowers, succeeded by quadrivalve pod-pods. This is of the humble sensitive kind, both leaves and footstalks receding from the touch.

7. The plena, annual, or double-flowered mimosa mimosa, rises with an herbaceous, erect, round, unarmed stem, closely branching and spreading every way, three or four feet high; bipinnated leaves of four or five pair of winged lobes, of many pairs of pinnae; and at the axillias and termination of the branches, spikes of yellow petaloid flowers, the lower ones double, succeeded by short pod-pods. This annual is only sensitive in the foliolas, but extremely sensible of the touch or air.

8. The cornigera, or horned Mexican mimosa, has a shrubby, upright, pricked stem, branching irregularly, armed with very large horn-like white spines, by pairs, connected at the base; bipinnated leaves thinly plac ed; and flowers growing in spikes. This species is esteemed for curiosity for the oddity of its large spikes, resembling the horns of animals, and which are often variously wretched, twisted, and contorted.

9. The barbatens, or fragrant acacia, grows in woods and waste lands in most parts of Jamaica; rising to 25 or 30 feet, with suitable thickness. Formerly the flowers of this tree were used as an ingredient in the thecias and androches, or the capers. The tree is sometimes planted for a hedge or fence round inclosures; and the timber, though small, is useful in rural economy.

10. The arbores, or wild tamarind-tree, is common in all the woods and openings, but nowhere where settlements have been made, in Jamaica. It rises to a considerable height, and is proportionally thick. The timber is excellent, and serves many purposes in rural economy, and is of the colour of cedar, pretty hard, and takes a good polish. The leaves are numerous; the flowers globular and white. The pods are about a foot in length, of a fine scarlet colour; when they ripe they open and become twisted. The seeds then appear.

11. The latifolia, slag-bark, or white wild tamarind. This excellent timber-tree is very common in Jamaica, and rises to a moderate height and good thickness. The trunk is rough and scaly; the leaves are numerous, of a rhomboidal figure, and yellowish, cast. The flower-spikes are from the axille; their colour is yellow. The seed-vessels are flat, jointed, and twisted, with the bigness of a vetch, white, and finely streaked with blue.

12. The lebeck, or ebony-tree. This is a native of the East Indies, but raised from seeds in Jamaica and St. Vincent. The tree is very small, and of a very hard wood. The flowers are red, and the manna taken from the sap is used for the manufacture of a fine sugar.

13. The scandens, caecum, or maltooloo, is frequent in all the upland valleys and woodlands on the north side of Jamaica. It climbs up the tallest trees, and spreads itself in every direction by means of its branches, or claspers, so as to form a complete arbour, and to cover the space of an English acre from one root. This circumstance has a bad effect on the trees or bushes so shaded; light, air, and rain, (so necessary for all plants,) being shut out, the leaves drop off, the tree gradually rots, and the limbs fall down by the weight of this parasite.

The roots of this plant run superficially under the ground or herbage. The trunk is seldom thicker than a man's thigh; and sends off many branches, with numerous shining green leaves, each of which terminates in a tendril or clasper, that serves to fasten it to the tree or bush. The flower-spikes are from the axille: they are slender, and the flowers on them small and numerous. The pod is perhaps the largest and longest in the world; being sometimes eight or nine feet in length,
five inches broad, jointed, and containing 10 or 13 seeds. These seeds are brown, shining, flattened, and very hard, and called carcons. They are the same as mentioned in the Philos. Herc. No. 222, page 261; and by Sir Hans Sloane, as being thrown ashore on the Hebrides and Orkneys.

This bean, after being long soaked in water, is boiled and eaten by some negroes; but, in general, there seems to be no other use made of it than as a sort of snauff-box.

15. The catechu, according to Mr. Ker (Med. Obs. and Inquir. vol. v. p. 131, &c.), grows only to 12 feet in height, and to one foot in diameter; it is covered with a thick, rough, brown bark, and towards the top divides into many close branches; the leaves are bipinnate, or doubly winged, and are placed alternately upon the younger branches; the partial pairs are nearly two inches long, and are commonly from 15 to 30 pair, having full glands inserted between the pinnae; each wing is usually furnished with about 40 pair of pinnule, or linear lobes, beset with short spines. From this tree, which grows plentifully on the mountainous parts of Indostan, where it flowers in June, is produced the official drug long known in Europe by the name of terra japo- nica.

16. The nilotica, or true Egyptian acacia, rises to a greater height than the preceding. The fruit is a long pod, resembling that of the lupin, and contains many flattish brown seeds. It is a native of Arabia and Egypt, and flowers in July. Although the mimosa nilotica grows in great abundance over the vast extent of Africa, yet gum arabic is produced chiefly by those trees which are situated near the equatorial regions; and we are told that in Lower Egypt the solar heat is never sufficiently intense for this purpose. The gum exudes in a liquid state from the bark of the trunk and branches of the tree, in a similar manner to the gum which is often produced upon the cherry-trees, &c. in this country; and by exposure to the air it soon acquires solidity and hardness. In Senegal the gum begins to flow upon the trees first opened, and the flowers continue during the rainy season till the month of December, when it is collected for the first time. Another collection of the gum is made in the month of March, from incisions in the bark, which the extreme dryness of the air at that time is said to render necessary. Gum arabic is now usually imported into England from Barbary, in large casks or hog-heads. The common appearance of this gum is well known; and various the figures which it assumes seem to depend upon a variety of accidental circumstances attending its transmu- nation and concretion. Gum arabic of a pale yellowish colour is most esteemed; on the contrary, those pieces which are large, tough, of a roundish figure, and of a brownish or reddish hue, are found to be less pure, and are said to be produced from a different spe- cies of mimosa; but the Arabian and Egyp- tian gum is contaminated with the mineral of this kind, similar to that which comes from the coast of Africa near the river Senegal.

Gum arabic does not admit of solution by spirit oil; but in twice its quantity of water it dissolves into a mucilaginous fluid, of the consistence of a thick syrup; and in this state answers many useful pharmaceutical purposes, by rendering oily, resinosous, and phlegmous substances, miscible with water. The glutinous quality of gum arabic is pre- sumably traced to two substances, as a demulcent in coughs, hoarse- nesses, and other catarhal affections, in order to obtain irritating acrimonious humours, and to supply the loss of abraded mucous. It has been very generally employed in pastes of arder urine and strangury; but it is the opinion of Dr. Cullen, "that even this mu- cilage, as an internal demulcent, can be of no service beyond the alimentary canal." The inner part of the Nilotic or Greek gum, is a kind of muscle, in which the vessels are large, and through which the water flows. It is more numerous in the East Indies, and was some time ago introduced into Jamaica. The flowers are globular, yellow, and fragrant. The pods are brown, and of the size of a goose-quill. The tree, on being wound, exudes gum arabic, though in less quantity, and less transparent, than that of the shops, which is obtained from the nilotica above described.

There are above 40 other species character- ized in Systema Vegetabilium.

MIMULUS, monkey flower, a genus of the dillenium angiospernia class of plants, with double stigmas, and a ringent monopetalous flower; the fruit is a bilocular carpel, with three seeds in each cell. There are three species.

MIMUSOPS, a genus of the octandra monogynia class of plants, the corollas of which consist of eight petals; and its fruit is a drupe. There are three species, tree of the East Indies.

MINA, in Grecian antiquity, a money of account, equal to a hundred drachms.

MINE, a deep pit under ground, whence various kinds of minerals are dug out; but the term is more particularly applied to those which yield metals. Where stones only are procured, the appellation of quarries is uni- versally bestowed upon the places from which they are dug out, however deep they may be.

The internal parts of the earth, as far as they have been yet investigated, do not consist of a homogeneous mass of one uniform substance, but of strata or beds of substances, extremely differ- ent in their appearances, specific gravities, and chemical qualities, from one another. Neither are these strata similar to one an- other, either in their nature or appearance, in different countries; so that, even in the short extent of half a mile, the strata will be found quite different from what they are in another place. As little are they the same either in depth or solidity. Incalculable cracks and fissures, by the miners called lodes, are found in every one of them; but these are so entirely different in size and shape, it is impossible to form any inference from their side in one place to that in another. In these lodes or fissures the metallic ore is met with; and, considering the great uncer- tainty of the dimensions of the lodes, it is evident that the business of mining, which depends on that size, must in like manner be quite unlimited; and therefore the miners must not suffer the vein to descend in any direction, but follow it as far as possible.

The sides of the fissures are commonly covered over with a hard, crystalline, earthy substance or rind, which very often, in the breaking of hard ore, comes off along with the fissure; and is only called the caps or walls of the lode.

The breadth of a lode is easily known by the distance between the two intrusted sides of the stones of ore; and if a lode yields any kind of ore, it is a better sign that the vein is regular and at least that one of them is so, than otherwise; but there are not many of these fissures which have regular walls until they have been sunk down some fathoms.

Thus the inner part of the fissure in which the ore lies is all the way bounded by two walls of stone, which are generally paralleled to one another, and include the breadth of the vein or lode. Whatever angle of inclina- tion some fissure may have, and however at their beginning, generally continue to do the same all along. Some are very uncer- tain in their breadth, as they may be small at their upper part and wide underneath; and vice versa. Their regular breadth, as well as their depth, is subject to great variation; for though a fissure may be many fathoms wide in one particular place, yet a little far- ther east or west it may not perhaps be one inch wide. This effect takes place generally in very compact strata, where the vein or fissure is squeezed, in a manner, through hard rocks which seem to press and straiten it. A true vein or fissure, however, is never entirely but always shows a string of metallic ore, or of a vein substance; which often serves as a leader for the miners to follow, until it sometimes leads them to a large and richly impregnated part.

The length of a fissure is not great in measure, unlimited, though not the space best fitted for yielding metal. The richest state for copper is from 40 to 50 fathoms deep; for tin, from 20 to 60; and though a great quality of either may be raised at 80 or 100 fathoms, yet the quantity is often too much decayed and dry for metal.

The fissures or veins of the Cornish mines extend from E. to W.; or, more properly, one end of the fissure points W. and by S., or W. and by N., while the other trends E. and by S. or E. and by N. Thus they fre- quently pass through a considerable tract of country with very few variations in their di- rection, and they are divided by some intervening cause. But, besides this east and west direction, we are to consider what the miners call the underlying, or lode, of the vein or lode, viz. the deflection or deviation of the fissure from its original line, as it is followed in depth like the slope of a house, or the descent of the steep side of a hill. This slope is generally to the north or south; but varies much in different veins, or sometimes even in the same vein; for it will frequently slope or underlie a small space in different ways, as it may appear to be forced by hard strata on either side. Some of the fissures do not vary much from a perpendicular, while some deviate more than a fath- som; that is, for every fathom they descend in perpendicular height, they deviate like- wise as much to the south or north. Others differ so much from the perpendicular that they assume a position almost horizontal; whereby they are also called flat or flat or lodes, and sometimes lode-plots. Another kind of these has an irregular position with regard to the rest, widening horizontally away, and then descending perpen- dicularly almost by a small string or leader to follow after; and thus they alternately vary, and yield ore in several flat
MINE.

or horizontal fissures. This, by the Cornish miners, is called a floor or squaw; which, properly speaking, is a hole or_space incogged with metal, making no continued line of direction or regular wall. Neither does a floor of ore descend to any considerable depth; for underneath it there appears no sign of a vein or fissure, either leading directly down, or any other way. This kind of vein is very rare in Britain. The fissures most common in Britain are the perpendicular and inclined, whether their direction is north or south, east or west.

The perpendicular and horizontal fissures probably remain little altered from their first position, when they were formed at the inclination of the strata immediately after the waters left the land. The perpendicular fissures are found more commonly situated in level ground, at a distance from hills, and from the sea-coast; but with regard to the latter, we find that the upper and under masses of strata differ in their solidity and other properties.

"Hence it is very plain that inclined fissures owe their direction or underlie to some extraordinary cause. Though the metallic veins generally run from east to west, they are frequently intersected by veins or lodes of other matters, which run from north to south. Some of these cross veins contain lead or antimony, but never tin or copper. Sometimes one of these unmetallic veins intersects the true one at right angles; sometimes obliquely; and sometimes the mixture of both is so intimate, that the searchers are at a loss to discover the separated part of a true vein. When this last is intercepted at right angles, it is moved, either north or south, a very little way, perhaps not more than half a mile, or two miles at the utmost. Sometimes the miners have worked to a small distance in one of these directions, if they find themselves disappointed, turn to the other hand, and seldom fail of meeting with what they expected. Sometimes they are directed in their search by the pointing of a rib or string of the true vein; but when the interruption happens in an oblique direction, the difficulty of finding the vein again is much greater.

When two metallic veins in the neighbourhood of each other run in an oblique direction, and of consequence meet together, they commonly produce a body of ore at the place where they intersect; and if both are rich, the quantity will be considerable; but if one is poor and all the other rich, it will not be required that the miners have worked to a small distance in one of these directions, if they find themselves disappointed, turn to the other hand, and seldom fail of meeting with what they expected. Sometimes they are directed in their search by the pointing of a rib or string of the true vein; but when the interruption happens in an oblique direction, the difficulty of finding the vein again is much greater.

Sometimes there are branches without the walls of the vein in the adjacent strata, which often come either obliquely or transversely into the strata, as if impregnated with ore, or if they underlie faster than the true vein (that is, if they dip deeper into the ground), then they are said to overtake or come into the lode, and to enrich it; or if they do not, then they are said to go off from it, and to impoverish it. But neither these, nor any other, marks, either of the richness or poverty of a mine, are entirely to be depended upon: for many mines, which have very bad appearance at first, do nevertheless turn out extremely well afterwards; while others, which in the beginning seemed very rich, turn gradually worse and worse: but, in general, where a vein has had a bad appearance at first, it will be imprudent to be at much expense with it.

Veins of metal, as has been already observed, are frequently compressed between hard strata that they are not an inch wide; and consequently, if the vein of good ore, it will generally be worth while to pursue them; and they frequently turn up well at last, after they have come into softer ground. In like manner, it is an encouraging thing to go on in the chambers of ore, and to enlarge either in width or depth as they are worked; but it is a bad sign if they continue horizontal without inclining downwards; though it is not proper always to discontinue the direction of a vein till a favourable object is met with at first. Veins of tin are worth working when only three inches wide, provided the ore is good; and copper ores when six inches wide will pay well for the working. Some of the great mines, however, have very large veins, with a number of other small ones very near each other. There are also veins crossing one another sometimes met with, which are called contras, or small counters. Sometimes two veins run down into the ground in such a manner that they meet in the direction of their depth; in which case the observations applied to them as are applicable to shafts that meet at right angles, or are perpendicular. The method of recovering their vein is to drive on their work in the direction of the former part, so that their new work shall make the same angle with the clay that the other part of the vein making at times they sink a shaft down from the surface; but it is generally a matter of difficulty to recover a vein when thus lost.

The method of discovering mines is a matter of so much difficulty, that it seems surprising how those who were totally unacquainted with the nature of metals first came to think of digging them out of the earth. In modern times we know that mines have been frequently discovered by accident; as by washing of the tides or floods; by the washing of the tides or floods; also by irrigations and torrents of water issuing out of hills and mountains, and sometimes by the wearing of high roads.

Mines, however, are now most commonly discovered by investigating the nature of such veins, ores, and stones, as may seem most likely to turn to account: but there is a particular sagacity, or habit of judging from particular signs, which can be acquired only by long practice. Many of those who acquire the art of knowing whether those vein of copper, may also be discovered by the harsh and disagreeable taste of the waters which issue from them; though it is probable that this only happens when the ore lies under the level of the water which breaks out; for it does not seem likely that the taste of the ore could ascend, unless we were to suppose a pond or lake of water standing above it. The presence of copper in any water is easily discovered by introducing in it a bit of polished iron, which will instantly be turned of a copper colour, from the precipitation of the metal upon it. A candle, or a piece of tallow, put into water of this kind, will in a short time be tinged of a green colour.

After the mine is found, the next thing to be considered is, whether it may be dug to advantage. In order to determine this, we are duly to weigh the nature of the place, and its situation; the nature of the water; the quality, healthiness, and the like; and compare the result with the richness of the ore, the charge of digging, stamping, washing, and smelting.

The form and situation of the spot should be particularly well considered, for no mine must either happen, 1. in a mountain; 2. in a hill; 3. in a valley; or, 4. in a flat. But mountains and hills are dug with much greater ease and convenience, chiefly because the drains and burrows, that is, the adits or avenues, may be here readily cut, both to drain the water, and to form gangways for bringing out the lead, &c. In all the four cases, we are to look out for the veins which the rains or other accidental circumstances may have laid bare; and if such a vein is found, it may often be proper to open the mine at that place, especially if the vein proves tolerably large and rich; otherwise mines may be more advantageously prospected by being determined upon for the purpose, viz. neither on a flat, nor on the top of mountains, but on the sides. The best situation for a mine is a mountainous, woody, wholesome spot, a safe passage, and a clear and wholesome river. The places abounding with mines are generally healthy, as standing high, and every where exposed to the air; yet some places where mines are found prove poisonous, and can upon no account be dug.

Devonshire and Cornwall, where there are a great many mines of copper and tin, are a very mountainous country, which gives an opportunity in many places to make adits or shafts and levels to the mine, without much distance, by which to carry off the water from the mine, which otherwise would drown them out from getting the ore. These adits are sometimes carried a mile or two, and dug at a vast expense, as from 2000l. to 4000l. especially where the ground is rocky; and yet they find this cheaper than to draw up the water out of the mine quite to the top, when the water runs in plenty, and the mine is deep. Sometimes the water is conveyed from a mine under a level near enough to which an adit may be carried from the bottom of the mine; yet they find it worth while to make an adit.
at half the height to which the water is to be raised, thereby saving half the expense.  

The late Mr. Coster, considering that sometimes from small streams and sometimes from little springs or collections of rainwater, one might have a good deal of water above ground, though not a sufficient quantity to answer the end to which it was intended, thought that if a sufficient full might be had, this collection of water might be made useful in raising the water in a mine to the adit, where it might be carried off.  

But now the most general method of draining mines is by the steam-cugue.

A Mine (in military affairs) is also a subterraneous cavity made according to the rules of art, in which a certain quantity of powder is lodged, which by its explosion blows up the earth above it.  

It has been found by experiment that the figure produced by the explosion is a paraboloid; and that the centre of the powder, or charge, occupies the focus.

The place where the powder is lodged is called the chamber of the mine, or foramen.

The passage leading to the powder is called the gallery.

The line drawn from the centre of the chamber, perpendicular to the nearest surface of the ground, is called the line of least resistance.

The pit or hole, made by springing the mine, is called the excavation.

The fire is communicated to the mine by a pipe or hose, made of coarse cloth, whose diameter is about one inch and a half, called a saucisson (for the filling of which near half a pound of powder is allowed to every foot), extending from the chamber to the entrance of the gallery; to the end of which is fixed a match, that the miner who sets fire to it may have time to retire before it reaches the chamber.

To prevent the powder from contracting any dampness, the saucisson is laid in a small trough, called an auger, made of boards, three inches and a half broad, joined together with straw in it, and round the saucisson, with a wooden cover nailed upon it.

**Galleries and chambers of mines.**—Galleries made within the fortification, before the place is attacked, in which several branches are carried to different places, are generally four feet or four and a half wide, and five feet or five and a half high.  

The earth is supported from falling in by arches and walls, if they are to remain for a considerable time; but when mines are made to be used in a short time, then the galleries are but three feet or three and a half wide, and five feet high, and the earth is supported by wooden frames or props.

The gallery being carried on to the place where the powder is to be lodged, the miners make the chamber.  

This is generally of a cubical form, large enough to hold the wooden box, which contains the powder necessary for the charge: the box is lined with straw and sand-bags, to prevent the powder from contracting dampness.

The chamber is sunk something lower than the gallery, if the soil permits; but where water is to be apprehended, it must be made higher than the gallery; otherwise the besieged will let in the water, and spoil the mine.

---

**Quantities of powder to charge mines.**—Before any calculation can be made of the proper charge for a mine, the density and tenacity of the soil must be ascertained, either by experiment, or otherwise; for in soils of the same density, that which has the greatest tenacity will require the greatest force to separate its parts.  

The density is determined by weighing a cubic foot (or any certain quantity) of the soil; but the tenacity can only be determined by making a mine.  

The following table contains experiments in six different soils, which may be of some use to form a judgment of the nature of the soil, when an actual experiment cannot be had:

**Loading and stopping of mines.**—The gallery and chamber being ready to be loaded, the strong box of wood is made of the size and figure of a box, and fastened to the side of the chamber, being about one-third or one-fourth bigger than is required for containing the necessary quantity of powder; against the sides and bottom of the box is put some straw; and this straw is covered over with empty sand-bags, to prevent the powder from contracting any dampness: a hole is made in the side next the gallery, near the bottom, for the saucisson to pass through; which is fixed to the middle of the bottom, by means of a wooden peg, to prevent its falling from the powder; or, if that, the enemy should get to the entrance, he may not be able to tear it out.  

This done, the powder is brought in sand-bags, and thrown loose in the box, and covered also with straw and sand-bags; upon this put the cover of the box, pressed down very tight with strong props; and, to render them more secure, planks are also put above them, against the earth, and wedged in as fast as possible.

This done, the vacant spaces between the props are filled up with stones and dung, and rammed in the strongest manner; the least neglect in this work will considerably alter the effect of the charge.

The auger is then laid from the chamber to the entrance of the gallery, with some straw at the bottom; and the saucisson laid in it, with straw over it; lastly, it must be shut with a wooden cover nailed upon it. Great care must be taken, in stopping up the gallery, not to press too hard upon the auger, for fear of spoiling the saucisson; which may hinder the powder from taking fire, and so prevent the mine from sprang; the gallery is stopped up with stones, earth, and dung, well rammed, six or seven feet further from the chamber than the length of the line of least resistance.

---

**MINERAL WATERS.** See Waters.

**MINERALOGY.** is that science which treats of the solid and inanimate materials of which our globe consists; and these are usually arranged under four classes: the earthly, the saline, the inflammable, and the metallic materials; which are classified into:

1. The earthly minerals compose the greater part of the crust of the earth, and generally form a covering to the rest. They are not remarkable for being heavy, brittle, or light-colored. They are liable to be extracted with ease, and are inadmissible in a low temperature, insipid, and without much smell.

2. The saline minerals are commonly moderately heavy, soft, sapid, and possess some degree of transparency.

3. The inflammable class of minerals is light, brittle, mostly opaque, of a yellow, brown, or black colour, seldom crystallized, and never feel cold.

4. Metallic minerals are characterized by being heavy, generally opaque, tough, malleable, cold, not easily inflamed, and by exhibiting a great variety of colours, of a peculiar kind.

Under each of these classes are various genera, species, sub-species, and kinds, which will be noticed in order. Sometimes, as in the vegetable kingdom, we find a strict affinity between different species of minerals, and in that case they are said to belong to the same family; but in mineralogy, one class does not always blend with another in a chemical point of view, or furnish that beautiful gradation and almost imperceptible union which is to be traced in the other kingdoms of nature.

As the external characters are of the first importance in facilitating our acquaintance with minerals, we shall briefly explain this subject, before we proceed to the classification of the different substances.

**Of the external characters of Minerals.**

The external characters of minerals are either generic or particular. The generic characters are certain properties of the mineral, without any reference to their differences, as colour, lustre, weight, &c.; and the differences between these properties form the specific characters.

Generic characters may be general or particular. In the first division are comprehended those that occur in all minerals, in the last those that are found only in particular classes of minerals.

The particular generic external characters are thus advantageously arranged:

1. **Colour.**

2. **Density**; distinguished into solid, friable, and fluid.

In solid minerals are to be regarded the external shape, the external surface, and the external lustre. When broken, the lustre of the fracture, the fracture itself, and the shape of the fragments, are to be noticed. In distinct concretions, regard must be paid to the shape of the concretions, their surface, their lustre, transparency, streak, and soilling. All of which may be ascertained by the eye. By the touch, we may discover the hardness of minerals their tenacity, friability, flexibility, their unctuousness, coldness, weight, and their adhesion to the tongue. By the ear we
MINERALOGY.

Aspect of the distinct Concretions.

The shape of the distinct concretions forms very prominent external characters. They may be granular, mineral in shape, or in minutiae; they may be lamellar, distinct, concretions, differing in the direction of the lamelle, in the thickness, with regard to shape, and in the position.

The surface of the distinct concretions may be smooth, rough, streaked, or uneven; as for their lustre, it may be determined in the same manner as the external lustre.

General Aspect as to Transparency.

Minerals, as is well known, have different degrees of transparency, which may be considered among their external characters. They may be transparent, semitransparent, translucent, or opaque.

The Streak.

The colour of this external character may be either similar or different. It is presented to us when a mineral is scraped with the point of a knife: and is similar, when the powder that is formed is of the same colour with the mineral, as in chalk; or dissimilar or different, as in cinnaemon, &c.

The Soiling or Colouring.

Is ascertained by taking a mineral specimen between the fingers, or drawing it across some other body. It may soil strongly, as in chalk, slightly, as in molybdana, or not at all, which is a quality belonging to most of the solid minerals. All the preceding external characters are recognized by the eye.

External Characters from the Touch.

These are eight in number, and are not destitute of utility to the mineralogical student.

Hardness may be tried by a capacity to resist the file, yielding a little to it, being semi-hard, soft, or very soft. Tenacity has different degrees, in substances being brittle, secrete or solid, or ductile. The frangibility consists in minerals being very delicately frangible, difficultly frangible, easily frangible, or very easily frangible. The flexibility is proved by being simply flexible, elastically flexible, commonly flexible, or inflexible.

The adhesion to the tongue may be strongly adhesive, pretty strongly, weakly, very weakly, or not at all. Uncutability may be maseate, rather greasy, greasy, or very greasy. Coldness is subdivided into cold, pretty cold, rather cold. Weight may be distinguished into swimming or supernatant, light, rather light, heavy, very heavy. The three last divisions from the touch, are in the Wernerian system regarded as anomalous; but they seem proper to be classed under this head.

External Characters from the Sound or Hissing.

The different kinds of sound which occur in the mineral kingdom are:

1. A ringing sound, as in native arsenic and thin splinters of horn-stone; 2. A grating sound, as in fresh-burnt clay; 3. A creaking sound, as that of natural amalgam.

1. Solid Minerals.

External aspect has three things to be regarded:

1. The shape; 2. The surface; and 3. The lustre. The external shape again.

Vol. II.

may be common, particular, regular, or extraneous; and hence arise the different specifiers.

1. The common external shape may be massy; disseminated, undulated, minutely, or finely; in angular pieces, sharp-cornered or blunt-cornered; in grains, large, coarse, small, fine, angular, flat, round; in plates, thick or thin; in membranes or flakes, thick, thin, or very thin.

The particular external shape may be longish, as dentiform, filiform, capillary, reticulate, dendritic, conchoidal, corticaliform, cylindrical, tubiform, claviform, or frustiform; roundish, as globular, spherical, ovoidal, spheroidal, amygdaloidal, botryoidal, reniform, tuberose, or fused-like; flat, as specular, or in leaves, cavernous, as in cellular forms, with impressions, perforated, corroded, amorphous, or vesicular; entangled, as ramosus, &c.

In the regular external shape or chrysallization are to be regarded its genuineness, according to which it may be either true or false; its shape, made up of planes, edges, angles, in which are to be observed the fundamental figure and its parts, the kind of fundamental figure, the varieties of each kind of fundamental figure, with their accidents and distortions, and the alterations which the fundamental figure undergoes by truncation, by bevelling, by acumination, or by a division of the planes. There are a variety of figures under each of these subdivisions.

It must be remarked also that the external shape may be extraneous, or derived from the animal and vegetable kingdoms, as in fossils and petrifications.

2. The external surface contains several varieties of distinctions. It may be uneven, granulated, rough, smooth, or streaked in various ways and directions.

3. The external lustre is the third generic external character, and is of much importance to be attended to. In this we have to consider the intensity of the lustre, whether it is splendid, shining, glistening, glimmering, or dull; next the sort of lustre, whether metallic or common. The latter is distinguished into semimetallic, adamantine, pearly, resinous, and vitreous.

Aspect of the Fracture of solid Minerals.

After the external aspect, the fracture forms no considerable character in minerals. Its lustre may be determined as in the external lustre; but the fracture itself admits of great varieties. It may be compact, splintery, coarsely splintery, finely splintery, even, conchoild, uneven, earthy, hackly; if the fracture is fibrous, we are to consider the thickness of the fibres, if coarse or delicate; the direction of the fibres, if straight or curved; and the position of the fibres, if parallel or diverging.

In the radiated fracture we are to regard the breadth of the rays, their direction, their position, their passage or cleavage. In the foliated fracture, the size of the folia, their degree of perfection, their direction, position, aspect of their surface, passage or cleavage, and the number of cleavages, are to be noted.

The shape of the fragments may also be very various, as cubic, rhombohedral, trapezoidal, &c. or irregular, as coniform, splintery, tabular, indeterminately angular.

C c

Distinguish their sound, and by the smell and taste the qualities which these two senses indicate.

In friable minerals, external shape, lustre, aspect of particles, soiling, and degree of friability, are to be attended to.

In fluid minerals the lustre, transparency, and fluidity, are principal objects to be regarded.

The specific external characters of minerals are founded on the distinctions and varieties of the two great generic divisions. And first, of colours, the names of which are derived from certain bodies in which they most generally occur, either in a natural or artificial state, or from different mixtures and compositions of both.

I. Colour.

1. White. This may be snow-white, reddish-white, yellowish-white, silver-white, greyish-white, greenish-white, milk-white, or tin-white.

5. Green. Verdigris-green, celadon-green, mountain-green, emerald-green, leek-green, apple-green, glaucous-green, pistachio-green, asparagus-green, olive-green, blackish-green, canary-green.

Besides these distinctions, colours may be clear, dark, light, or pale; they may have a tarnished appearance, a play, a changeable, an irreducible, an opalescence, a permanent alteration, and a delineation of figure or pattern, such as dotted, spotted, clouded, flamed, striped, veined, dendritic, or rainiform.

II. Cohesion of Particles.

Minerals are divided into, 1. Solid, or such as have their parts coherent, and not easily movable; 2. Friable, or that state of aggregation in which the particles may be overcome by simple pressure of the finger; and, 3. Fluid, or such as consist of particles which alter their place in regard to each other by their own weight.

1. Solid Minerals.

External aspect has three things to be regarded, 1. The shape; 2. The surface; and 3. The lustre. The external shape again.
MINERALOGY.

2. Friable Minerals.

The external characters drawn from minerals of this class are derived, first, from the external shape, which may be massive, disseminated, thinly coating, spumous, or dendritic; secondly, from the lustre, regarded under its intensity, whether glimmering or dull, and its sort, whether common glimmering or met-lic glinting; thirdly, from the aspect of the particles, as being dusty or scaly; fourthly, from shining or colouring, as strongly or lightly; and lastly, from the fluidity, which may be loose or cohering.

Of external characters drawn from fluid minerals, there are only two kinds, which include three varieties: 1. The lustre, which is either metallic, as in mercury, or resinous, as in rock oil. 2. The transparency, which is transparent, as in naphtha; turbid, as in mineral oil; or opaque, as in mercury. 3. The fluidity, which may be fluid, as in mercury or viscous, as in mountain tar.

External Characters from the Smell.

There may be spontaneously emitted and described: astringent, faintly subacrid, or faintly bitter; or they may be produced by breathing on, and yield a clay-like smell; or they may be excited by friction, and smell urinous, subacrid, garlick-like, or empyreumatic.

External Character from the Taste.

This character prevails chiefly in the saline class, and it contains the following varieties: a sweetish taste, sweetish astringent, styptic, saltly bitter, saltly cooling, alkaline, or urinous.

Having now given a Synopsis view of the external characters of minerals, we shall proceed to their classification, and in this we shall chiefly follow the names and arrangement of professor Jameson.

CLASS I. EARTHY FOSSILS.

First Genus. Diamond.

Diamond.

This precious stone has great variety of shades, exhibiting a beautiful play of colours. It occurs in indeterminate angular and completely spherical grains, which presents planes of crystallization, or are actually crystallized. Its fundamental chrysolite is the octaedron, which passes into various forms. It is hard in the highest degree, brittle, not very diffusely fragrable, and has a specific gravity of 3.600.

The diamond has, by modern experiments, been proved to be nearly pure carbon, and begins to burn at 14° or 15° of Wedgewood. See Plate I, Mineralogy, figs. 1, and 2.

Second Genus. Zircon.

First Species. Zircon.

The prevailing colour is grey, but it occurs likewise green, blue, red, yellow, and brown, with various intermediate tints. It is found most commonly in roundish angular pieces, with rounded angles and edges. When crystallized, the figure is generally a rectangular four-sided prism, some-

what flatly acuminate by four planes, set on lateral planes; but of this figure there are several varieties. The chrysolites are almost always very small, have a smooth surface, bordering on strongly splendent. Internally, the lustre is very splendent, passing into adamantine. Fig. 3.

Zircon is hard in a very high degree, brittle, fragrable without great difficulty. Specific gravity 4.700. It forms a colourless transparent mass with borax, but is insubflable by the blowpipe without addition.

Found in the island of Ceylon, where it was first discovered, and lately in Norway, imbedded in a rock composed of hornblende and felspar.

Frequently cut as a precious stone, and used as an inferior kind of diamond, of which it was once considered as a variety. Its play of colours very considerable.

Second Species. Hyacinth.

The chief colour is red, passing to reddish-brown, and to orange-yellow. The figure a rectangular four-sided prism, flatly acuminate by four planes, which are set in the lateral edges. Of this figure, however, several varieties occur.

The chrysolites are generally small, and all imbedded. The lateral planes smooth, and externally shining. Internally it is splendent and glassy, inclining somewhat to resinous. Fig. 4.

The hyacinth is transparent, very hard, fragrable without particular difficulty; feels a little greasy when cut, and has a specific gravity of about 4.000.

It is fusible with borax. Exposed to the blowpipe it loses its colour, but not its transparency.

Occurs in rocks of the newest flint trap formation, and sometimes in sand. It is native of Ceylon, the country of gems; of Spain, of Portugal, France, Italy, Saxony, and probably Scotland.

It takes a fine polisli, and when the colours are good, it is highly valued. A third species, called cinnamon stone, has lately been discovered at Columbo, in Ceylon.

Third Genus. Flint.

First Species. Chrysoberyl.

The prevailing or general colour is apergas-green, passing into a variety of allied shades. It exhibits a milky-white light; occurs in roundish and angular grains, which sometimes approach in shape to the cube. It is seldom crystallized; but when in this state, it commonly presents a longish six-sided table, having truncated lateral edges, and longitudinally streaked lateral planes. The chrysolites are small, externally shining, and internally splendent. Fig. 5.

It is hard, very easily fragrable, with a specific gravity of 3.600. Without addition, it is insubflable.

The chrysoberyl is found in Brazil, and in the sand of Ceylon. It is sometimes set in rings with a yellow foil, but is rarely in the possession of our jewellers.

Second Species. Chrysolite.

The chief colour is pistachio-green, of all degrees of intensity. It occurs in original angular sharp-edged pieces, with a rough, scaly, splinter surface, and when crystallized, exhibits a broad rectangular four-sided prism, with its lateral edges sometimes truncated, sometimes bevelled, and acuminate by six planes. Fig. 6.

The external surface of the chrysolite is splendent, internally splendent, and vitreous.

Third Species. Olivine.

The colour is generally asparagus-green, of various degrees of intensity. It is found imbedded also in roundish pieces and grains; and when crystallized, which is rare, in rectangular four-sided prisms.

Internally, it is shining, varying between glistening and splendent. It is semitransparent, very easily fragrable; in a low degree hard, and not particularly heavy. It is nearly insubflable without addition. Occurs imbedded in basalt; is frequently found in Bohemia, and also in Hungary, Austria, France, England, Ireland, Scotland, Sweden, Iceland, and Norway. Pieces as large as a man's head have been found in some parts of Germany.

Fourth Species. Augite.

The general colour is blackish green. It occurs chiefly in indeterminate angular pieces and roundish grains. Occasionally it is crystallized, and presents broad rectangular four-sided prisms. The chrysolites are mostly small. Internally the lustre is shining, approaching sometimes to splendent.

The augite is only translucent, and but faintly fragrable. It is hard, not very easily fragrable, and not particularly heavy.

It is found in basalt, either singly or accompanied with olivine, in Bohemia, Hungary; at Arthur's Seat, near Edinburgh; in some of the Hebrides, and in Norway. From olivine it is distinguished by its darker colours, the form of its crystallization, and its greater hardness.

Fifth Species. Vesuvian.

Its principal colour is dark olive-green, passing into other allied shades. It occurs massive, and often crystallized in rectangular four-sided prisms. The chrysolites are mostly short, and placed on one another. Externally their surface alternates between glistening and splendent. Internally they are glistening, with a lustre between vitreous and resinous.

The vesuvian is translucent, hard in a moderate degree, and approaching to heavy. Before the blowpipe it melts without addition.

It is found among the exuviae of Vesuvius, from whence it derives its name, in Cilesia and Kaukaschka. At Naples, it is cut into ring-stones, and sold under various names.

Sixth Species. Leucite.

The colours are yellowish and greyish-white. It occurs mostly in original round and angular grains. When crystallized, it exhibits acute-double eight-sided pyramids. Internally it is shining, and approaching to glistening, with a vitreous lustre, inclining somewhat to resinous.

The leucite is translucent and semitransparent. It is hard in a low degree, brittle, easily fragrable, and not very heavy. It is insubflable without addition. With borax, it forms a brownish transparent glass.

It is found in rocks of the newest floetz.
MINERALOGY.

The chrysalis are small and middle-sized. Internally the lustre is splendid and vitreous. It is more or less transparent in different localities, and is variegated, when cut, exhibits a star of six rays. Fig. 8.

The sapphire is hard in the highest degree, but yields to the diamond; it is easily frangible, and rather heavy, having a specific gravity of about 4.000.

It is infusable without addition: occurs in rocks of the newest flint trap formation, and is supposed to be an immaculate granite, syenite, and other primitive rocks.

This precious stone is found in the utmost beauty in Pegu and Ceylon. It is also a native of Portugal, of France, and of Bohemia. Next to the diamond, it is the most valuable of gems, and is used in the finest kind of jewellery.

It should be observed, that the violet-colored sapphire is the oriental amethyst; that the yellow is the oriental chrysolite and topaz; and that the green is the oriental emerald.

The principal colour is greenish-white, of various degrees of intensity. It occurs in small, middle-sized, and large crystals, and is generally round or oval, and crystallized. The crystallizations resemble those of the sapphire, and the crystals are middle-sized and imbedded.

The corundum is duplicating translucent, hard in a high degree, pretty easily frangible, and approaches to heavy. It is supposed to occur imbedded in granite, syenite, or green-stone, and is found in the Carnatic and on the coast of Malabar. See Corundum.

The colour is a dark hair-brown. It occurs massive, disseminated, in rolled pieces, and crystallized in six-sided prisms, or very acute six-sided pyramids. Internally, its lustre is splendid, approaching in a slight degree to adammite. It may be cut so as to present an opalescent star of six rays, of a peculiar pearly light. It is translucent on the edges, hard in a high degree, easily frangible, and not particularly heavy.

The diamond spar probably occurs in granite. It has hitherto been found only in China. Both this stone and corundum are employed in cutting and polishing hard minerals, and they seem to be nearly allied to each other.

Emery is hard in the highest degree, not very easily frangible, and is heavy. It occurs in beds of talc and slate, and is frequently accompanied with talc spar and blende. It is found in Saxony, in the islands of the Archipelago, in Spain, Normandy, and is said also to be a native of the isles of Guernsey and Jersey.

It is of great use in cutting and polishing hard bodies.

The chief colour is a wine-yellow, of all degrees of intensity. It is found massive, disseminated, and sometimes rolled, but most commonly crystallized in oblique eight-sided or four-sided prisms, which exhibit several varieties. The chrysolite are small and middle-sized, externally splendid; internally, and shining: lustre vitreous.

The topaz alternates from transparent to heavy, and is not particularly heavy. It is infusible with borax; and some kinds in a gentle heat turn white, and are sometimes sold for diamonds.

It is commonly found in veins that traverse primitive rocks in Brazil, Siberia, in Pegu, and Ceylon; in Bohemia, Saxony, and Cornwall. Exhibiting various forms and figures, it has often been confounded with other precious stones. It is much used in seals and rings.

The green called emerald is the characteristic colour of this species, but it has all degrees of intensity from deep to pale. It is said to occur massive and in rolled pieces, but most commonly crystallized in low equiangular six-sided prisms. The chrysolite are middle-sized and small. Internally the lustre is intermediate between shining and splendid, and is vitreous. It alternates from transparent to translucent, and is duplicating translucent.

The emerald is hard, not particularly heavy, melts easily with borax, but is scarcely fusible before the blowpipe. It occurs in veins that traverse clay-flat, and at present occurs only found in South America, particularly in Peru, though the Romans are said to have procured it from Egypt and Ethiopia.

From the beauty and vivacity of its colour, the charming emblem of the vegetable kingdom, this precious stone is much admired, and employed in the most expensive kinds of jewellery. See Emerald.

This is divided into two sub-species, the precious and the schorlous beryl. See Beryl, and fig. 9.

The colour is commonly clove-brown, of various degrees of intensity. It is occasionally found massive, more frequently disseminated; but generally crystallized in very flat and oblique rhombs. Externally, its lustre is generally splendid; internally, it alternates from glistening to shining, and is vitreous.

This species alternates from perfectly transparent to weakly translucent. It is pretty hard, very easily frangible, and not particularly heavy. It appears to be peculiar to the primitive mountains, and is found imbedded in limestone in Saxony, Dauphiny, Norway, Siberia, and Cornwall. Fig. 11.

The colour a yellowish-brown, bordering on liver-brown. It occurs commonly massive, but also crystallized in small equiangular six-sided prisms. Externally, its lustre is splendid; internally, shining, and is intermediate between vitreous and resinous.

Iron-flint is opaque, and slightly translucent on the edges. It is pretty hard, some-
MINERALOGY.

First Sub-species. Common Chalcedony.

The most common colour is grey. The external shape is various, being massive, in blunted-edged grains and rolled pieces, in original round balls, &c. &c. Internally, the chalcedony is also almost always flat, commonly semitransparent, hard, brittle, rather difficultly friable, and not particularly heavy. It occurs in amygdaloidal, and in porphyry; and is found in Transylvania, in Iceland, Siberia, Cornwall, Scotland, and the Hebrides. Being susceptible of a fine polish, it is employed as an article of jewellery.

Second Sub-species. Carnelian.

The principal colour is a blood-red, of all degrees of intensity. It commonly occurs in roundish pieces, and also in layers: the lustre is glistening, bordering on glistening, and semitransparent. See CARNELIAN.

Agate.

The fossils known under this name are all compound substances; and hence cannot have a particular place in any systematic arrangement. We have therefore placed them as a supplement to the species chalcedony, which forms a principal constituent part of them, and dispose them according to their color-delineations, thus: 1. Fortification agate; 2. Landscape agate; 3. Rhomb agate; 4. Moss agate; 5. Tube agate; 6. Clouded agate; 7. Land agate; 8. Star agate; 9. Fragment agate; 10. Punctuated agate; 11. Petrification agate; 12. Coal agate; 13. Jasper agate. They are all compounds of chalcedony, carnelian, jasper, horn-stone, quartz, heliotrope, amethyst, indurated lithomarge, and opal, in different quantities and proportions; and are found in great abundance in Germany, France, England, Scotland, Ireland, and the East Indies.

The uses of agate are various. It is cut into vases, mortars, smalt-boxes, seals, handles to knives, and for many other useful purposes. See AGATE.

Twenty-ninth Species. Heliotrope.

The principal colour is intermediate between leek and dark celadon green, or mountain green, massive, and in angular as well as rolled pieces. Internally the lustre is glistening, and is always resinosous. It is commonly translucent in the edges; is easily friable, hard, and not particularly heavy. Heliotrope is found in rocks belonging to the floetz trap formation, in Asia, Persia, Siberia, Saxony, and Iceland.

On account of its beautiful colour and its hardness, it is employed for nearly the same purposes as agate. See HELIOTROPE.

Twenty-fourth Species. Flint.

The general colour is grey, but with many varieties. It occurs massive, in regular plates, in angular grains and species, in globular and elliptical rolled pieces, in the form of sand, and tuberosous and perforated. Sometimes it is chrysallized, when it exhibits double six-sided prisms, or flat double three-sided prisms. Internally, the lustre is glistening, translucent on the edges, hard, easily frangible, and not particularly heavy.

Twenty-fifth Species. Chaledony.

This is divided into two sub-species, chalcedony and carnelian.

First Sub-species. Common Chalcedony.

The most common colour is grey. The external shape is various, being massive, in blunted-edged grains and rolled pieces, in original round balls, &c. &c. Internally, the chalcedony is also almost always flat, commonly semitransparent, hard, brittle, rather difficultly friable, and not particularly heavy. It occurs in amygdaloidal, and in porphyry; and is found in Transylvania, in Iceland, Siberia, Cornwall, Scotland, and the Hebrides. Being susceptible of a fine polish, it is employed as an article of jewellery.

Second Sub-species. Carnelian.

The principal colour is a blood-red, of all degrees of intensity. It commonly occurs in roundish pieces, and also in layers: the lustre is glistening, bordering on glistening, and semitransparent. See CARNELIAN.

Agate.

The fossils known under this name are all compound substances; and hence cannot have a particular place in any systematic arrangement. We have therefore placed them as a supplement to the species chalcedony, which forms a principal constituent part of them, and dispose them according to their color-delineations, thus: 1. Fortification agate; 2. Landscape agate; 3. Rhomb agate; 4. Moss agate; 5. Tube agate; 6. Clouded agate; 7. Land agate; 8. Star agate; 9. Fragment agate; 10. Punctuated agate; 11. Petrification agate; 12. Coal agate; 13. Jasper agate. They are all compounds of chalcedony, carnelian, jasper, horn-stone, quartz, heliotrope, amethyst, indurated lithomarge, and opal, in different quantities and proportions; and are found in great abundance in Germany, France, England, Scotland, Ireland, and the East Indies.

The uses of agate are various. It is cut into vases, mortars, smalt-boxes, seals, handles to knives, and for many other useful purposes. See AGATE.

Twenty-ninth Species. Heliotrope.

The principal colour is intermediate between leek and dark celadon green, or mountain green, massive, and in angular as well as rolled pieces. Internally the lustre is glistening, and is always resinosous. It is commonly translucent in the edges; is easily friable, hard, and not particularly heavy. Heliotrope is found in rocks belonging to the floetz trap formation, in Asia, Persia, Siberia, Saxony, and Iceland.

On account of its beautiful colour and its hardness, it is employed for nearly the same purposes as agate. See HELIOTROPE.

Twenty-fourth Species. Flint.

The general colour is grey, but with many varieties. It occurs massive, in regular plates, in angular grains and species, in globular and elliptical rolled pieces, in the form of sand, and tuberosous and perforated. Sometimes it is chrysallized, when it exhibits double six-sided prisms, or flat double three-sided prisms. Internally, the lustre is glistening, translucent on the edges, hard, easily frangible, and not particularly heavy.

Twenty-fifth Species. Chaledony.

This is divided into two sub-species, chalcedony and carnelian.

First Sub-species. Common Chalcedony.

The most common colour is grey. The external shape is various, being massive, in blunted-edged grains and rolled pieces, in original round balls, &c. &c. Internally, the chalcedony is also almost always flat, commonly semitransparent, hard, brittle, rather difficultly friable, and not particularly heavy. It occurs in amygdaloidal, and in porphyry; and is found in Transylvania, in Iceland, Siberia, Cornwall, Scotland, and the Hebrides. Being susceptible of a fine polish, it is employed as an article of jewellery.

Second Sub-species. Carnelian.

The principal colour is a blood-red, of all degrees of intensity. It commonly occurs in roundish pieces, and also in layers: the lustre is glistening, bordering on glistening, and semitransparent. See CARNELIAN.

Agate.

The fossils known under this name are all compound substances; and hence cannot have a particular place in any systematic arrangement. We have therefore placed them as a supplement to the species chalcedony, which forms a principal constituent part of them, and dispose them according to their color-delineations, thus: 1. Fortification agate; 2. Landscape agate; 3. Rhomb agate; 4. Moss agate; 5. Tube agate; 6. Clouded agate; 7. Land agate; 8. Star agate; 9. Fragment agate; 10. Punctuated agate; 11. Petrification agate; 12. Coal agate; 13. Jasper agate. They are all compounds of chalcedony, carnelian, jasper, horn-stone, quartz, heliotrope, amethyst, indurated lithomarge, and opal, in different quantities and proportions; and are found in great abundance in Germany, France, England, Scotland, Ireland, and the East Indies.

The uses of agate are various. It is cut into vases, mortars, smalt-boxes, seals, handles to knives, and for many other useful purposes. See AGATE.

Twenty-ninth Species. Heliotrope.

The principal colour is intermediate between leek and dark celadon green, or mountain green, massive, and in angular as well as rolled pieces. Internally the lustre is glistening, and is always resinosous. It is commonly translucent in the edges; is easily friable, hard, and not particularly heavy. Heliotrope is found in rocks belonging to the floetz trap formation, in Asia, Persia, Siberia, Saxony, and Iceland.

On account of its beautiful colour and its hardness, it is employed for nearly the same purposes as agate. See HELIOTROPE.
This species is divided by Werner into five sub-species. 1. Mealy zeolite; 2. Fi- brous zeolite; 3. Radiated zeolite; 4. Cubic zeolite. As they are principally distinguished from each other by fracture, hardness, and lustre, we shall only observe, that the chief colours of all are yellowish, whitish, and reddish, with a variety of intermediate shades; that zeolite occurs massive, in angular pieces, in balls, and sometimes crystallized in short and oblique four-sided prisms, and in perfect smooth clinoidal cubes; that it is according to the sub-species opaque, translucent, or even transparent; and that it is semihard, easily fracturable, and not particularly heavy. Zeolite occurs in rocks belonging to the newest formation, but it is sometimes, though rarely, found in primitive green stone, either disseminated, in cotemperaneous balls, or filling up air cavities or veins. All the different sub-species are natives of Scotland. The mealy zeolite is found in the Isle of Skye; the fibrous and radiated in the isles of Canary and Sky; the silted in Staffa, and the cubic in the same isle, and likewise in Sky. The mealy zeolite is met with in Iceland, in Sweden, in Germany, and the East Indies. Figs. 13 and 14.

Thirty-third Species. Cross-Stone. The colour is a greyish-white. It occurs crystallized, either in broad rectangular four-sided prisms, or in twin crystals. The crystals are mostly small, and aggregated on one another. Both the internal and the external lustre are shining, inclining to splendent or glistering. The cross-stone is translucent passing to transparent, semi-hard, easily fracturable, and not particularly heavy. It has hitherto been found only in mineral veins, and in agate-balls, at Strenton, in Argyleshire, and at Andeasberg, in Hartz, as well as some other places.

Thirtieth Species. Agate-Stone. The colour is a perfect azure blue, of different shades. It is found massive, disseminated, and in rolled pieces. The lustre is glistening and glistering. It is translucent on the edges, pretty hard, brittle, easily fracturable, and not particularly heavy. The geometrical situation is not correctly ascertained. It is said to have been found near the lake of Baikal, in Siberia, in a vein accompanied with garnet, felspar, and pyrites. It occurs in Persia, China, Tartary, and Siberia; in South America; but in Europe has only been found among the ruins of Rome. Its beautiful colour renders it an object of attraction, and being capable of receiving a high polish, it is applied to various useful purposes, and enters into the composition of many different ornaments. It is the lupis lazuli of painters. Werner is constantly making additions to his species under every genus. Of those belonging to the flint genus, which are less known, and have been described with less precision than the preceding, are coroc/sites, found in Sweden and Elb- way; pistazie, found in Norway, Bavaria, and France; ceylanite, in Ceylon; enclose, in Peru; hvite, near Frankfort; menilite, near Paris; sionite, in Lower Britannia; natrolite, in Subbia; aurete, in Sturia, &c.; andalusite, or hardspar, in Saxony, France, and Spain; chiastolite, or hollow spar, in France and Spain, and probably in Cumberland, in Norway; and arzitze, or wermerte, in Sweden, Norway, Switzerland, and Lazulite.

Fourth Genus. Clay Genus. First Species. Jasper. This is divided into six sub-species; Egyptian jasper, striped jasper, porcelain jasper, common jasper, agate jasper, and opal jasper.

Second Species. Opal. Werner divides this into four sub-species, precious opal, common opal, semi-opal, and wood opal.

Third Species. Pitch-Stone. The colours are black, green, brown, red, and occasionally grey. It occurs always massive in great beds and rocks. Internally, its lustre is shining. It is commonly translucent in a small degree, brittle, and pretty easily fracturable.

Pitch-stone is fusible without addition; occurs in beds between the porphyry and flint clay formation; and is found in Saxony, Hungary, in several of the Hebrides, and in Dumfriesshire. Some of its varieties bear a striking resemblance to pitch, from whence it receives its appellation.

Fourth Species. Obsidian. The principal colour is green-violet. It always occurs in angular roundish-pieces. Internally it is splendent. Some of the varieties are translucent, others semi-transparent. It is hard, easily fracturable, and not very heavy.

Obsidian occurs insular in the newer porphyry formation, and is found in Hungary, Ireland, in Persia, and various other countries. When cut and polished, it is sometimes used for ornamental purposes, and mirrors for telescopes have been formed of it. It probably owes its origin to fire.

Fifth Species. Pearl Stone. Its colour is generally grey, sometimes black and red. It occurs vesicular, and the vesicles are long and roundish, with a shining pearly lustre. It is translucent on the edges, not very brittle, very easily fracturable, and rather light.

Pearl stone is found in beds of porphyry, near Falkay, in Hungary, in the north of Ireland, and the Hebrides.

Sixth Species. Pumice Stone. Its usual colour is a light yellowish-grey, passing into different neighbouring shades. It is small, and lengthened ovoidal; its internal lustre glistening, generally translucent in the edges, soft, and seldom semi-hard, very brittle, easily fracturable, and swims in water.

It occurs in various situations, generally accompanied by rocks that belong to the flint trap formation; and though usually classed among volcanic productions, in some situations it evidently is of aqueous origin. It is found in the Lipari islands, in Hungary, Iceland, and on the banks of the Rhine; and is used for polishing stones, metals, glass, and ivory; and also for preparing parchment.

Seventh Species. Feldspar Is divided into four sub-species; compact felspar, common felspar, adularia, and Labradorite. Fig. 15.

Eighth Species. Pure Clay Is snow white, with occasionally a yellowish tinge, and occurs in kidney-shaped pieces, which have no lustre. It is opaque, soils very little, adheres slightly to the tongue, is light, and intermediate between soft and friable.

Pure clay is found immediately under the soil, accompanied with baked clay and scleulate, at Halle, in Saxony, only.

Ninth Species. Porcelain Earth. The colour is generally a reddish-white, of various degrees of intensity. It occurs massive and disseminated; its particles are fine and dusty, slightly colored, and feeling fine and light. It is found in beds in gneiss, accompanied with quartz and other substances, in Saxony, at Passau, Limoges, and in Cornwall. In China and Japan, where it is called kaolin, it is very abundant. It forms the basis of china ware.

Tenths Species. Common Clay. This is divided into six sub-species, as follows:

1. Loam, of a yellowish-grey colour, frequently spotted with yellow and brown, and occurring massive. It is dull and weakly glimmering, colours a little, adheres pretty strongly to the tongue, and feels slightly greasy. It is often mixed with sand, gravel, and iron ochre.

2. Potter's clay is of two kinds, earthy and slaty. The earthy is of a yellowish-grey, greyish-white colour in general; occurs massive; is opaque, colours a little; feels somewhat greasy, and adheres strongly to the tongue. Slaty potter's clay is generally of a dark ash-grey colour, and feels more greasy than the preceding. It occurs in great rock masses, and is found in various places, universally distributed, and of great importance in the arts and in domestic economy.

3. Pipe clay is greyish-white, passing into yellowish-white, occurring massive, of a glimmering lustre, and having its particles pretty coherent. It feels rather greasy, is easily fracturable, and adheres pretty strongly to the tongue.

4. Variegated clay is commonly white, red, and yellow, striped, veined, and spotted. It occurs massive, is soft, passing into triable, feels a little greasy, and adheres somewhat to the tongue. It is found in Upper Saxony.

5. Clay-stone is commonly grey or red, with various intermediate tints. It occurs massive, is dull, opaque, soft, pretty easily fracturable, feels rather meagre, and does not adhere to the tongue. It forms vast rock masses, occurs in beds and veins, and is found in Saxony, in Scotland, and in Shetland.

6. Slate clay is of a grey colour, presenting several varieties. It is massive, internally
dull, opaque, pretty soft, mild, easily francible, adheres a little to the tongue, and feels meagre. It is generally found wherever the oval, floetz trap, and stratum formation occurs.

Eleventh species. Poller, or Polishing-Stone.

Is of a yellowish-grey colour, striped, and the colours alternate in layers. It occurs massive, is dull, very soft, adheres to the tongue, feels fine but meagre, and is nearly swimming. It is found in the vicinity of pseudo-volcanoes, though hitherto it has only been discovered in Bohemia.

Twelfth species. Tripoli.

Is of a yellow-brown colour, passing into ash-grey; occurs massive, is internally dull, very soft, feels meagre and rough, does not adhere to the tongue, and is rather light. It is found in veins and beds in floetz rocks in Saxony, in Derbyshire, and many other counties of England. Tripoli, from whence it was first brought. Its use in polishing metals and minerals is well known.

Thirteenth species. Alum-Stone.

Is of a greyish-white colour, occurs massive, shews a tendency to crystallization, is soft, passing to friable, and light. It is found at Tolfa, near Rome, from whence the famous Roman alum is manufactured.

Fourteenth species. Alum Earth.

The colour is a blackish-brown, and brownish-black; it is massive, dull, feels a little meagre, and somewhat greasy; is intermedium between soft and friable, and light. It is found in beds of great magnitude in alluvial land, and in floetz trap formation in several parts of Germany, in Naples, and in France. It is Sixted in order to obtain the alum it contains.

Fifteenth species. Alum-Slate.

Is divided into two sub-species, as follow: 1. Common alum-slate is between a greyish and bluish-black colour, occurs massive, and in beds, is soft, not very brittle, easily fracible, and not very heavy. 2. Glossy alum-slate is of an intermediate colour, between blueish and iron-black; occurs massive, with a shining semi-metallic lustre, and in other respects resembles the former. It is found in beds and strata in Saxony, France, Scotland, and Hungary; and affords considerable quantities of alum.

Sixteenth species. Bismiumous Slate.

Is of a brownish-black colour, and occurs massive. Internally, its lustre is limnering; it is very soft, rather mild, feels rather greasy, is easily frangible, and not particularly heavy.

It is found with clay-slate in the coal formation, in Bohemia, England, Scotland, and other coal countries.

Seventeenth species. Drawing Slate, or Black Chalk.

Its colour is a greyish-black, with a tinge of blue; it occurs massive, is opaque, colours and writes, is soft, mild, easily frangible, feels meagre, but fine, and is rather light.

It is found in primitive mountains in France, Germany, Iceland, Scotland, and the Hebrides. When a middling degree of hardness, it is used for drawing.

Eighteenth species. Whit-Slate.

The common colour is greenish-grey; it is massive; internally, weakly glimmering, semi-hard, feels rather greasy, and is not particularly brittle or heavy. It occurs in primitive mountains in Saxony, Bohemia, and the Levant. When cut and polished, it is used for sharpening knives and tools.

Nineteenth species. Clay-Slate.

Its principal colour is grey, with which there are many varieties. It occurs massive; internally, its colour is glistering, the substance opaque, soft, pretty easily frangible. It is found in vast strata in primitive and transitory formation, particularly in Scotland. When split into thin and firm tablets, it is used for roofing houses, and other purposes.

Twentieth species. Lepidolite.

Its colour is a kind of peach-blossom, red, verging on lilac-black, and occurs massive. Its internal lustre is glistering; it is translucent, soft, easily frangible, and easily melts before the blowpipe. Hitherto it has only been found in Moravia, where it lies in gneiss.

Twenty-first species. Mica, or Glitter.

Its common colour is grey, of great variety of shades. It occurs massive, disseminated in thin tables and layers in other stones, and crystallized either in equilateral six-sided tables, or in six-sided prisms. The surface of the crystals is splendent; internally, shining and splendent. In thin plates, it is transparent, but in larger masses only translucent on the edges. It is semi-hard, feels smooth, but not greasy, elastic, flexible, and more or less easily frangible.

It forms one of the constituent parts of granite, gneiss, and mica slate, and is almost peculiar to the primitive mountains. It was formerly used instead of glass, for windows and lanterns. Fig. 16.

Twenty-second species. Pot-Slate.

Its colour is a greenish-grey, of different degrees of intensity; it is massive, lustre, internally, glistering and pearly, translucent on the edges; soft, feels greasy, and is very difficultly frangible.

It occurs in beds, or is indurated; and is found in the country of the Greeks, in Saxony, and probably in Hudson's-bay, and is nearly allied to indurated tale.

Twenty-third species. Chlorite, Which see.

Twenty-fourth species. Hornblende, Which see. See also fig. 17.

Twenty-fifth species. Basalt.

The usual colour is greyish-black, of various degrees of intensity. It occurs massive, in blunt and rolled pieces, and sometimes vesicular. Internally, it is commonly dull. It is usually found in distinct concretions, which are generally columnar, and sometimes upwards of 100 feet in length. Commonly opaque, semi-hard, brittle, very difficultly frangible, melts without addition, and is almost exclusively confined to the floetz trap formation. It occurs in strata, beds, and veins, in almost every quarter of the globe, and is very abundant in Scotland, Ireland, and in other parts of the British and European dominions. It is useful for building, as a touch-stone, as a flux, and in glass manufactures.

Twenty-sixth species. Wauce.

The colour is a greenish-grey, of various degrees of intensity. It occurs massive and vesicular, is dull, somewhat glimmering, opaque, usually soft, more easily frangible, and not particularly heavy.

It is said to belong exclusively to the floetz trap formation, where it occurs in beds and above clay, and also in veins. It is found in Saxony, Bohemia, and Sweden.

Twenty-seventh species. Clink-Stone.

Is commonly of a dark greenish-grey colour, always massive, and occurring in irregular and generally concretion. It is usually translucent on the edges, brittle, easily frangible, and when struck with a hammer, sounds like a piece of metal.

It is said to belong to the floetz trap formation, and generally concretion. It is found in Lusitania, Bohemia, South America, and in the isle of Lambath, in the frith of Clyde.

Twenty-eighth species. Lava.

Is divided into two sub-species.

1. Slag lava is of a greyish-black colour, passing into other strata. Externally, it is always vesicular and distinct concretions. It is generally opaque, semi-hard, brittle, easily frangible, and not particularly heavy.

2. Foam lava is of a dark greenish-grey colour, occurs small and fine, vesicular; externally, glimmering, slightly translucent on the edges, brittle, easily frangible, and light. It has often been contended with pumice-stone, from which, however, it differs very much. On account of its lightness, it is used with advantage in arching vaults, and other kinds of building.

Twenty-ninth species. Green Earth.

Its colour is a calcead green, of various degrees of intensity. It occurs massive, in angular and globular pieces, and also disseminated. Internally, it is dull, streak glistering, very soft, easily frangible, and light. It is principally found in an Eskdale, in Saxony, Bohemia, Scotland, and other places, and is used by painters.

Thirtieth species. Lithomage.

Is divided into two sub-species.

1. Friable lithomage, or rockmarrow, is snow-white, or yellowish-white, occurs massive, as a crust, and disseminated; is generally coherent, feels greasy, and adheres to the tongue. It is found in veins, in Saxony.

2. Indurated lithomage is most commonly white, which presents several varieties; is massive; internally, dull; streak shining, very soft, easily frangible, feels greasy, and adheres strongly to the tongue. It occurs in veins of porphyry, &c. in Saxony, Bohemia, Bavaria, &c.

Thirty-first species. Rock Soap.

Is of a brownish or pitch-black colour, occurring massive, in a bluish-grey stone, and is generally soft, adhering to the tongue, feels greasy, and adheres strongly to the stone. It occurs in veins, in Saxony, Bohemia, etc.
MINERALOGY.

Seventh species. Serpentine, Which see.

Eighth species. Schiller-Stone. Its colour is olive-green, usually disseminated and massive; lustre shining, is soft, highly brittle, and easily frangible. It occurs imbedded in serpentine, and is found in the Harz, in Saxony, Cornwall, and Ayrshire. It is often confounded with Labrador hornblende.

Ninth species. Talc. This is divided into three sub-species.

1. Earthy talc is of an intermediate colour between greenish-white and light greenish-grey; friable, strongly glistening, soils a little, feels rather greasy, and occurs in thin veins near Freyberg in Saxony.

2. Common, or Venetian talc, is principally of an apple-green colour, massive and disseminated, and in delicate and small tabular crystals. It is almost always splendid and shining, translucent in thin leaves transparent, flexible, but not elastic; soft, easily frangible, feels very greasy, and approaches to light.

3. Indurated talc is of a greenish-grey colour, of various degrees of intensity, occurs, shining, passing to glistening, strongly translucent on the edges, soft, feels rather greasy, and is frangible without particular difficulty. It is found in primitive mountains in Tyrol, Austria, Scotland, and the Shetland isles.

Tenth species. Asbestos. See Asbestos.

Eleventh species. Cyanite, Which see.

Twelfth species. Actinolite Is divided into the following sub-species:

1. Asbestos actinolite is of a greenish-grey colour, occurs massive, disseminated, and is capillary crystals; is internally glistening, translucent, on the edges, soft, brittle, not easily frangible, nor particularly heavy. It is found in mineral beds in Saxony, and other parts of Germany.

2. Common actinolite is generally of a green tinge-colour, passing into other shades of the same; it occurs massive, and, likewise chryostalized in very oblique six-sided prisms, is spangled externally, semi-hard, rather brittle, and not easily frangible.

It is found in beds in primitive mountains, in Saxony, Switzerland, Norway, and Scotland.

3. Glassy actinolite is principally of a mountain-green-grey colour, of various degrees of intensity; occurs massive, or in thin six-sided chrysotile, is shining and vitreous, strongly translucent, brittle, easily frangible, semi-hard, and is found in similar situations with the preceding.

Thirteenth species. Tremolite. This is divided into the following sub-species:

1. Asbestos tremolite is of a whitish colour with a tinge of yellow, grey, red, or green; it occurs massive, and in capillary and acicular crystals; internally glistening, very soft, easily frangible, and translucent on the edges.

2. Common tremolite is nearly of the same colour as the preceding, occurs massive, and in long and very oblique four-sided prisms; internally opaque, translucent and semi-transparent, semi-hard, and very easily frangible.

3. Glassy tremolite is yellowish, reddish, greyish, and greenish-white; occurs massive, and is chryostalized. Internally, it is shining and translucent; composed of very thin prismatic concretions, which are again collected into very thick prismatic concretions. It is translucent, brittle, and very easily frangible, soft, and sometimes very soft, very easily frangible, feels meagre, and rather rough; effervesces strongly with acids, and is confounded principally on the sea-coast, though the Chiffren range in England is wholly composed of it. It is used for polishing and cleansing metals, glass, &c. and in some places as a manure, and cement in building.

Third species. Lime-Stone Is divided into several sub-species:

1. Compact limestone is of two varieties, common compact limestone, and roe-stone. The former is generally of a grey colour, but is frequently veined, zoned, striped, or clouded; occurs massive, and in rolled pieces; is translucent on the edges, semi-hard, brittle, very easily frangible; is almost entirely composed, like lime in general, to the floetz mountains; occurs in sand, stone, and coal formations, in England, Scotland, and many other countries; and is frequently used for building or making roads, or, when burnt, for manure and cement.

The latter, or roe-stone, is of a chesnut-brown colour, is massive; internally dull, composed of small and fine-grained globular distinct concretions; semi-hard, brittle, not very easily frangible; occurs in beds in considerable quantities in Saxony, and is solely used for manure, for which its admixture with marl admirably fits it.

2. Foliated limestone is likewise of two kinds, granular limestone, and calc spar (calc spar, foliated, and calc spar, foliated)' the former is commonly whitish, but presents many varieties of that colour; is massive, occurs almost always in

massive and disseminated, dull, opaque, does not soil, writes like drawing slate, is easily frangible, and easily tended. It is found imbedded in rocks of the flint trap formation, in Poland, and in the isle of Skye, but is very rare, and found only in small quantities.

Thirty-second species. Yellow Earth. The colour is ochre-yellow, of different degrees of intensity; it is massive, streak shining, is soft, and, strongly adheres to the tongue, and feels somewhat greasy. It occurs in beds with iron-stone, in Upper Saxony, and is employed as a pigment.

To the clay genus, likewise, belong adhesions, slate, float-stone, pine, andumber, which may be considered as recent discoveries.

FIFTH GENUS.

Talc Genus.

First species. Bole.

Its colour is cream-yellow, passing into various other shades; is commonly massive, very soft, and, strongly adheres to the tongue, and feels somewhat greasy. It occurs in rocks belonging to the new flint trap formation, and is found in beds of warece or basalt, in Silesia, Italy, &c.

It was formerly employed in medicine, but is now used only as a pigment.

Second species. Native Talc Earth.

The colour is yellowish-grey, passing into cream-yellow. It occurs massive, tuberous, and of other shapes; is internally dull, almost opaque, soft, frangible without much difficulty, and adheres a little to the tongue.

It is found in beds of serpentine, but only hitherto in Moravia.

Third species. Mekrauham. The usual colour is yellowish-white. It occurs massive, is internally dull, opaque, streak shining, is soft, adheres strongly to the tongue, feels a little greasy, and is nearly swimming. It is principally found in Natal, in Samoa, Hungary, Moravia, Spain, and America. It is much used in the manufacture of colour for paper, &c.

It is said that the Turks eat it as a medicine.

Fourth species. Fuller's Earth.

The colours are greenish-white, grey, olive, and oil-green. It is massive; internally dull, usually opaque, gives a shining streak, is very soft, feels greasy, and is not particularly heavy.

It is found in different situations in England, Saxony, Alasce, and Sweden; and is of essential use in cleansing woollen cloth, from which property it receives its name.

Fifth species. Neaphrite, Which see.

Sixth species. Scrotle. The principal colour is white, of which it presents many varieties. It occurs massive, disseminated, in crusts, and chryostalized in six-sided prisms. Internally it is dull, streak shining, very soft, rather difficultly frangible, and feels greasy.

It is found in beds and veins in serpentine in Norway, Sweden, Saxony, England, Scotland, and China. It is used in the manufacture of porcelain, and for other purposes.
granular distinct concretions, is more or less translucent, semihard, brittle, easily fracturable, is peculiar to the primitive and transitional mountains, and is chiefly found in Italy, whence it is distributed over Europe, for the purpose of statuary. The white marble of Paros, or granular limestone, has long been celebrated. Scotland furnishes some beautiful varieties of marbles, whose uses are well-known.

The latter, or calc spar, is principally white, but has many shades. It occurs massive, disseminated, and crystallized, either in six-sided prisms, or three-sided prisms. The lustre alternates from splendent to shining and glistening, and is most commonly vitreous. The massive varieties are translucent, and sometimes even transparent. It is found venuous in almost every rock from granite to the newest flint bed, occurs in a great variety of mineral veins, and is very universally disseminated, but is found particularly beautiful in Derbyshire, in Ireland, Saxony, France, Germany, and Spain.

3. Fibrous limestone, is of two varieties, common fibrous limestone, and fibrous limestone, or calc spar. The former is composed of fibres, of very different lengths, yellowish-white, or yellowish-grey, or white, or greyish, or black; it occurs massive, and only in small veins. The latter, or calc spar, is principally white, of which it exhibits several beautiful varieties; occurs massive, and also in many particular external forms; internally it is glistening and pearly. It is commonly found in the limestone cliffs and rocks of the coast, it is also found in almost every limestone country. It is composed of fibres of various lengths, and is still used in statuary.

4. Pea-stone is commonly yellowish-white, massive, internally dull, opaque or translucent on the edges; soft, very easily fractured, and in great masses in the vicinity of the hot springs at Carlsbad in Bohemia. It is composed of spherically round distinct concretions. All the varieties of limestone effervescence with acids.

Fourth species. Scheum, or foaming earth.

It is principally a light yellowish colour; occurs massive and disseminated; is intermediate between shining and glistening, presents large, coarse, small, and fine-grained distinct concretions; is generally opaque, soft, completely friable; feels fine, but not greasy, and cracks a little. It is found in cavities of the oldest flint limestone in Thuringia, and in the north of Ireland.

Fifth species. Slate spar.

Its colour milky, and greenish or reddish-white; occurs massive; lustre intermediate between shining and glistening, and completely pearly; fragments sly, translucent, soft, and prettily easily fracturable. It is found in the grey, red, or yellow veins, in the mountains, and is produced in Norway, Saxony, and Cornwall.

Sixth species. Brown spar.

This is divided into the following sub-species:

1. Foliated brown spar, is principally white and red, with several varieties of each. It occurs massive, globular, with tabular impressions, and frequently crystallized, externally shining, internally alternating from shining to concretion. It is found in granular, distinct concretions of all magnitudes; is yellow or more or less translucent, semihard; a little difficultly fracturable, and occurs in veins generally accompanied with calc spar, &c. in the mines of Norway, France, Germany, England, and other countries.

2. Fibrous brown spar is of a flesh-red, passing into rose-red; occurs massive, lustre glistening, fragments splintery, in other respects resembling the preceding. Hitherto it has been found only in Hungary and Transylvania.

Seventh species. Rhomb spar.

Its colours are yellowish and greyish-white; occurs only in regular middle-sized rhombs; lustre splendent, generally intermediate between translucent and semitransparent; is semihard, brittle, easily fracturable, and is found imbedded in rocks belonging to the calc gypsum in Sweden, Switzerland, and on the banks of Loch-Iommond in Scotland.

Eight species. Schalensteine.

The most common colour is grey-yellow; it occurs massive, and sometimes disseminated through gyps, is dull or glistening internally, translucent on the edges, rather soft, easily fracturable, and when rubbed, emits a pungent smell. It is found in considerable quantities in the district of Mansfield in Thuringia.

Tenth species. Marle.

Which see.

Eleventh species. Bituminous marble slate.

Its colour is intermediate between greyish and brownish-black; it is massive, from glistening to shining, fragments sly, usually soft, easily fracturable, and streak shining. It is found in beds along with the oldest flint limestone, and contains much copper intermixed with it, on account of which it is usually smelted in Thuringia.

Twelfth species. Calc tuff.

The colour is yellowish-grey; it is generally perforated or marked with the impressions of other substances, also amorphous, amorphous, and corroded. Internally dull, substance opaque, soft, easily fracturable, and approaching to shining. It occurs in alabaster, and is found in Thuringia, at Gouta, and other places in Germany.

Thirteenth species. Arragon.

The principal colours are greenish-grey, and iron red. It occurs crystallized in perfect equiaxial six-sided prisms: the lustre is glistening, passing into shining, and is vitreous; it is semihard, brittle, not particularly heavy, and purpuresces a little. It was first discovered in the province of Aragon, whence its name, imbedded in gyps, but has since been found in some other countries of the continent.

Fourteenth species. Apophite.

The usual colours are white, green, blue, and red; it generally occurs crystallized, the radical form of which is the equiaxial six-sided prism.Externally it is splendent, internally shining and resinous. It is commonly transparent, semihard, brittle, easily fracturable, and occurs in tin veins in Saxony, Bohemia, and in Cornwall. It has been found with schools, &c. Fig. 20.

Fifteenth species. Asparagus or spargel stone.

The principal colour is asparagus-green; it occurs only crystallized in equiaxial six-sided prisms, is internally shining, most frequently translucent, semihard, easily fracturable, and brittle. Hitherto it has been found only in Moravia in Switzerland, supposed to be produced in Norway. It is nearly allied to apophtite. Fig. 21.

Sixteenth species. Boraxite.

Its colours are yellowish, smoke and greyish white, passing to asparagus-green; it occurs in crystallized cubes, with the edges and angles truncated, internally shining, commonly semihard, brittle, and easily fracturable. Hitherto it has been discovered only at Luzenburg in Hanover. Fig. 22.

Seventeenth species. Flour.

Which see, also fig. 23.

Eighteenth species. Gyps.

This is divided into the following sub-species:

1. Gyps earth is of a yellowish-white colour, passing into some allied shades, is intermediate between fine sily and dusty, dull and feebly glistening, soils a little, feels mucilaginous but soft and fine, and is light. It is found, though rarely, in gyps countries, and is formed in the same manner as rock milk, is used as a manure.

2. Compact gyps, is commonly ash-grey, passing into smoke and yellowish-grey, is massive, internally dull, frequently translucent on the edges, very soft, fracturable without great difficulty, and is employed in architecture and sculpture, under the name of travertine.

3. Foated gyps is commonly white, grey, or red, presenting spotted, striped, and veined colour delineations. It occurs massive, and in blunted-edged pieces, but seldom in crystals. Internally it alternates from shining and glistening to glancing, is translucent and duplicating, very soft, and not particularly difficultly fracturable. It has been confounded with granular limestone. It forms glassy spar, and is found under various names of each. It occurs massive and dentiform, the internal lustre is usually glistening and pearly, commonly semihard-transparent and translucent, very soft and easily fracturable.

Fossils belonging to the gyps formation, occupy different situations. They are found in Switzerland, Switzerland, Derbyshire, Cornwall, Morfet in Scotland, and other places. Chips, when burnt, forms an excellent cement, and is used for many ornamental purposes.

Nineteenth species. Scolecite.

Its principal colour is snow-white, passing into other neighbouring shades: is generally
MINERALOGY.

massive, but not infrequently crystallized in pretty oblique six-sided prisms, the crystals seldom large, but internally shining and splendid. Fig. 24.

Selenite is completely transparent, soft, somewhat resistant, and not very fragile, and is found in the oldest gypse formation, in single crystals in clay beds in the newest formation, and in other situations. It is common in Thrangia, in Montmartre near Paris, in Cornwall, and in the Isle of Sheppey. It is employed in taking the most delicate impressions, for crayons and other purposes.

Twentieth species. Cube spar.

The colour is milk-white with various allied shades. It is massive, occurring in large, coarse, and small ground distinct concretions. The lustre is shining, passing into splendent, translucent, soft, very easily frangible, and not particularly heavy. It is found in salt rocks in Salzbourg.

To the calc genus are also referred phosphorite, which has a great bed in Estremadura in Spain; and the anhydrite, found in the duchy of Wirtemberg.

First species. Witherite.

Is commonly of a light yellowish-grey colour, generally massive, but sometimes chryslalized in six-sided prisms, or double six-sided pyramids. The lustre of the principal fracture is shining; the fragments generally wedge-shaped. It is translucent, somewhat semihard, brittle, easily frangible, and pretty heavy. Figs. 23 and 26.

It melts, without addition, before the blowpipe, into a white enameled, and occurs in veins along with heavy spar, lead-glance, &c. at Angiescar in Lancashire. Combined with ammoniacal acid, it may be used in medicine, though a very active poison of itself.

Second species. Heavy spar or baryte. See Barytes.

Eighth genus. Strontian genus.

First species. Strontian.

The usual colour is intermediate between asparagus and apple-green; it occurs most commonly massive, but sometimes chryslalized in a circular six-sided prism. The crystals are scabiously and manipulably aggregated. The lustre of the principal fracture is shining, the cross fracture glistening. It is translucent in a greater or less degree, soft and semihard, brittle, easily frangible, dissolves in acids with effervescence, and occurs along with lead-glance, heavy spar, &c. at Strontian in Argyleshire, the only place where it has yet been found.

Second species. Celestine. Is divided into two sub-species:

1. Fibrous celestine, is at an intermediate colour, between indigo-blue and bluish-grey; it occurs massive and in plates, and also chryslalized, displaying a tendency to primary distinct concretions; is translucent, soft or semi-hard, easily frangible, and pretty heavy. It is found in Pennsylvania and in France.

2. Foliated celestine, is of a milky-white colour, frequently into blue; it occurs massive, and also chryslalized in six-sided tables in

CLASS II. Fossil SALTs.

The substances included in this class are confided to those which are found in a natural state only; and the greater part of them appear to be formed by the agency of water, air, &c.

The distinguishing characters of fossil salts are, their taste and easy solution. They resemble each other so closely, that the term saline consistence is used to express whatever relates to hardness, tenacity, and friableness.

First species. Natron, or Natural Soda. It may be divided into the two following sub-species:

1. Common natron, is of a yellowish or greyish-white colour, occurs in fine flakes or in massive, pale grey or white crystalline species. It occurs along with salts of nitre, effervescing with nitric acid, is easily soluble in water, and strikes blue vegetable tinctures green. It occurs as an efflorescence in the surface of soil, or on the sides and bottoms of lakes that occasionally become dry. It is found in very large quantities in Hungary, Bohemia, and Egypt, and in many other countries of the Old World.

2. Radiated natron, or natural soda, is of a greyish or yellowish-white colour, occurs in crusts or chryslalized in capillary or accicular crystals, is glistening and translucent, and is found in large quantities in the province of Sukana in Berabhi, and in Southern Africa.

Natron is principally employed in the manufacture of glass, soap, and for washing. It is also used as a flux after being purified.

Second species. Natural nitre.

The colour is greyish or yellowish-white, approaching to snow-white; it is flaky, sometimes verges to solid and massive, is of a saline consistence, and tastes saltly and cooling. Placed on hot iron, it hisses and detoneates; is usually found in thin crusts on the surface of the soil at particular seasons of the year, particularly in hot climates. It is also met with in various countries of Europe, and is much used in making gunpowder, in medicine, and the arts. The greatest part, however, employed for these purposes, is an artificial preparation from the refuse of animal and vegetable bodies, undergoing putrefaction, and mixed with calcareous and other earth.

Third species. Natural Rock-salt. Is divided into two sub-species:

1. Rock or stone-salt, which is of two kinds, foliated and fibrous. The former is commonly of a grey or greyish colour, occurs massive and disseminated, and also chryslalized in cubes; in general is strongly translucent, rather hard, easily frangible, and feels somewhat greasy. The latter is greyish, yellowish, and snow-white; it occurs massive, is strongly translucent, vergeing to semi-transparent, decrepitates when laid on burning coals, and is found in beds lying over the first or oldest flint trap formation. It forms large beauty at Cornubia; it is found also in Germany, and almost every country in the world. At Nautwich in Cheshire it has long been dug. Its use is as general as its dissemination. It is employed as a daily seasoning for our food, as a mainer, in various manufactories, and for purposes too numerous to mention.

2. Lake-salt occurs either in thin plates, which are formed on the surface of salt-lakes, or in grains at their bottom. It is translucent, and of a saline consistence. It is found in Cyprus, near the Caspian Sea, and in various parts of Africa.

Fourth species. Natural sal ammoniac.

The colour is commonly greyish or yellowish-white. It is of a saline consistence, and is flaky, with an unitious taste. It is sometimes used in manufacture. It is called blue rose, by twilight, and chrysalized. It is the product of volcanoes and pseudo-volcanes, and is found in Italy, Sicily, in the vicinity of inflamed beds of coal both in England and Scotland, and in several countries of Asia.

Fifth species. Natural Epsom salt.

Colour a greyish-white. It occurs in crystals of a saline consistence, and grows saltly bitter. It is found as an efflorescence on clayey stones or gypse rocks, at Sesa, at Solifarina, in Hungary, and Bohemia. It is also contained in many mineral springs, particularly those of Epsom, and is derived from its name. Epsom salts are much used as an easy purgative. Considerable quantities of magnesia may be obtained from them.

Sixth species. Natural Glanaber salt.

The colour is usually greyish and yellowish-white. It occurs in the form of mealy effluviences, in crusts, and sometimes chryslalized in capillary and hexagonal crystals. Internally it is shining, with a vitreous lustre, is soft, brittle, easily frangible, and has a cooling but a saltly bitter taste. It is found on the borders of salt-lakes, on noxious ground, on old and new-built walls, in different countries of Europe, Asia, and Africa, and is used as a purgative medicine, and in some as a substitute for soda in the manufacture of white glass.

Seventh species. Natural alum.

It is of a yellowish or greyish-white colour; occurs as a mealy efflorescence, or in delicate capillary chryslals; has a sweetish astrangent taste, and is produced in various situations in Scotland, Germany, Italy, Spain, Sweden, and in Egypt.

Alum is employed as a mordant in dyeing, in the manufacture of leather, as a medicine for preventing wood from catching fire, and for preserving animal substances from putrefaction.

Eighth species. Hair salt.

The principal colours are snow, yellowish, and greyish-white. It occurs in delicate capillary chryslals, has a saline consistence, and a sweetish astrangent taste. Hair salts is found in different mine countries on the continent, at Whitby in England, and near Paisley in Scotland, and bears a striking resemblance to fibrous gypse.

Ninth species. Rock butter.

The colour is light-yellow or greyish-white. It occurs massive and tubercular; it is translucent, has a saline consistence, or sweetish-sour
MINERALOGY.

Tenth species. Natural vitriol

Is divided into the three following sub-species.

1. Iron vitriol, is commonly of an emerald and verdigris green. It occurs massive, tuberose, stalactic, and chrysotallized in different figures; is splendent and vitreous, has a saline consistence, and a sourish astringent taste. It is found along with iron pyrites, by the decomposition of which it is formed, in different countries of continental Europe, in many of the English mines, and in America. It is employed to dye linen yellow, and wool and silk black, in the preparation of inks, as a pain, &c.

2. Copper vitriol, is usually of a dark blue or black colour. It occurs massive, disseminated, stalactic, dendritic, and chrysotallized in various mining countries, in Wicklow, and in Anglesea. It is used in cotton and linen printing, and when prepared is employed by painters.

3. Lead vitriol, is a greyish, yellowish, reddish, and greenish colour. It occurs tuberose, stalactic, and coralloidal, is translucent, of a saline consistence, and a stypic taste. It is produced most abundantly where much blende occurs, and is found in Austria, Hungary, and Sweden. Here it must be remarked, that borax, though so well known by name, is without a place in the Wernerian system, as it is uncertain whether or not it occurs in a solid state. It is most probable that it occurs only in solution in certain lakes. See Borax.

The new genus stallicite, of which only one species, cryolite, has been found in Greenland, seems properly to come under this head.

CLASS III.

Inflammable Fossils.

Fossils belonging to this class are light, brittle, mostly opaque, yellow, brown, or black, seldom chrysallized, and never feel cold. They are more nearly allied to the metallic than to the earthy or saline classes.

First Genus. Sulphur Genius.

First species. Natural sulphur.

It contains the following sub-species:

1. Common natural sulphur, is of the colour the name expresses, but of different degrees of intensity. It occurs massive, disseminated, and chrysotallized in octeadehrons or double six-sided pyramids, is internally between shining and glistening, translucent, in chrystals frequently transparent, very soft, easily frangible, and light.

It is found in masses in gyps, in veins that traverse primary rocks, nests of limestone, and in other situations, and is produced in every quarter of the world, though in the British dominions it seems to be confined to Ireland.

2. Volcanic natural sulphur is of the colour the name imports, but with a considerable tinge of green. It occurs corroded, vesicular, perforated, amorphous, and sometimes as a submate in flowers, is glistening and resinous, and translucent in a slight degree. It is found only in volcanic countries, and among lava, but is produced in great abundance; and is employed in medicine, in the composition of gunpowder, and as a vapour in whitening wool and silk.

Second Genus. Bituminous genus. See Bitumens.

Fourth Genus. Graphite genus.

First species. Glance coal.

This is divided into two sub-species:

1. Conchoidal glance coal, is of an iron-black colour, of different degrees of intensity, occurs massive and vesicular, internally shining, bordering sometimes on semilunar, brittle, easily frangible, and light. It burns without flame or smell, and has hitherto been found only in the newest fossils mass formation, accompanied with other kinds of coal, at Meissen in Saxony. The fracture is conchoidal.

2. Slaty glance coal, is of a dark iron-black colour, occurs massive, is shining and glistening, soft, easily frangible, light, and intermediate between semilunar and brittle. It is found imbedded in masses, beds, and veins, in primitive, transitive, and fossil rocks, and is produced in Spain, Savoy, Saxony, Bohemia, and in the Isle of Arran in Scotland. Its principal fracture is more or less slaty.

Second species. Graphite.

This contains two sub-species:

1. Scaly graphite, is commonly of a dark steel-grey colour. It occurs massive if disseminated, is usually glistening, fracture scaly-siluted, is very soft, perfectly sectile, writes and soils, feels very greasy, and is rather difficult to frangible.

2. Compact graphite, is rather blacker than the preceding, is internally glistening with a metallic lustre, fracture fine-grained, in other respects agreeing with the preceding. It usually occurs in beds, and is found near Kold, in Ayrshire, Scotland, and in various other parts of Europe, Asia, and Africa. The finer kinds are first boiled in oil, and then cut into pencils. The course parts and sawings are melted with sulphur, and that part of the pencils used.

The colour is very light steel-grey, approaching to silver-white. It occurs in flat, smooth, and smallish grains, externally shining, lustre metallic, intermediate between semilunar and brittle, sometimes in beds, and in veins. Its principal fracture is more or less slaty. It is found in various countries, in Sweden, Norway, &c. Eas, and according to some, it has been found in the alluvial land near London. It admits of a fine polish, and is cut into necklaces, bracelets, small-boxes, and various other articles. The oil and acid obtained from it are used in medicine.

Second species. Honey-stone. See Mellite.

CLASS IV.

Metallic Fossils.

First, Platina genus.

First species. Native platina.

The colour is very light steel-grey, approaching to silver-white. It occurs in flat, smooth, and smallish grains, externally shining, lustre metallic, intermediate between semilunar and brittle, sometimes in beds, and in veins. Its principal fracture is more or less slaty. It is found in various countries, in Sweden, Norway, &c. Eas, and according to some, it has been found in the alluvial land near London. It admits of a fine polish, and is cut into necklaces, bracelets, small-boxes, and various other articles. The oil and acid obtained from it are used in medicine.

Second genus. Gold.

First species. Native gold.

This is divided into three sub-species:

1. Gold-yellow native gold, is of a perfect colour, corresponding to its name. It seldom occurs entire, is often in membranous, and in small and thin flat pieces, in grains, and also chrysallized in cubes, octahedrons, simple three-sided pyramids, deltoidododecahedrons, and acute double eight-sided pyramids. It is abundant in the crystals of the world, but commonly in too small quantities to be collected for use. America and Africa supply the largest quantities.

2. Brass-yellow native gold, is principally of the colour of brass, occurs disseminated, capillary, moss-like, reticulated, and in leaves, also chrysallized in thin six-sided cubes, and is rather lighter than the preceding. It is found in different situations in Bohemia, Hungary, &c.

3. Greyish-yellow native gold, is of a brass-yellow color falling into steel-grey, occurs in small flatish grains like platina, and is found with that metal.

Third genus. Mercury, which see.
MINERALOGY

First species. Native mercury, or quick-silver.

The colour is tin-white; it occurs perfectly fluid in globular drops, or as a metallic lustre, does not wet, feels very cold, and is uncommonly heavy. Before the blow-pipe it is volatilized, without any smell. It is usually found in cinnabar at Idria. It occurs in a compact limestone, and here it is very abundant. It is likewise produced in different parts of Germany, France, Spain, and in very large quantities in Peru. The uses of quicksilver are multifarious, and cannot be enumerated in this place.

Second species. Natural amalgam.

Fluid or semi-fluid amalgam is of an intermediate colour between tin and silver-white. It occurs in small massive pieces and in balls, also disseminated and chrystralized in different forms.Externally it is shining and splendent, soft and somewhat fluid; when cut or pressed, it emits a cracking sound like natural amalgam, and is uncommonly heavy.

Third species. Mercurial hova-ore, or corrosive mercury.

It is of an ashy-grey colour, of various degrees of intensity; occurs very rarely massive, but commonly in small pieces, internally chrystralized and splendent. It is soft, sectile, easily friable, and heavy. It is usually found with the other species of mercury, and is produced in the same countries. It was first discovered in the mines of the Palatinate.

Fourth species. Mercurial breore, or mercurial lenticular arc.

Compact mercurial liver-ore, is of an intermediate colour between dark-red and lead-grey, occurs massive, is glistening and glimmering internally, opaque, soft, sectile, easily friable, and uncommonly heavy. It is the most common ore of mercury at Frein in Idria.

Fifth species. Cinnabar.

Dark-red cinnabar, is principally of a perfect coelestial red, occurs massive, disseminated, in large broken pieces, in membranes, amorphous, dodecahedrons, and crystallized. The crystals are small, splendent externally, and shining internally. The massive cinnabar is opaque or translucent on the edge, brittle, sectile, softly friable, and uncommonly heavy.

Bright-red cinnabar is of a lively scarlet-red colour. It occurs massive and disseminated, is internally glimmering, substance opaque, streak shining, soot, is very soft, sectile, very easily friable, and heavy. Both belong to the same countries with quicksilver. In Idria, Spain, and Peru, this genus is most abundant. It does not occur in Norway, Sweden, or Great Britain, or Ireland. From the ore of cinnabar the greatest part of the mercury used in commerce is obtained.

Fourth Genus. Silver.

First species. Native Silver.

Common native silver is of the colour the name expresses. It occurs massive, disseminated, in pieces, plates, and membranes, as well as in other forms; besides being chrystralized in cubic, octahedrons, garnet, dodecahedrons, and double eight-sided pyramids. Externally it is shining and glistering; internally it alternates from shining to glistering, and has a metallic lustre. It is soft, completely malleable, pretty flexible, and uncommonly heavy, containing upwards of 80 parts of pure silver; and is found in veins, along with native silver and other minerals, in Hungary, Austria, and other countries of Europe, but more particularly in Mexico and Peru.

Seventh species. Brittle silver-glance.

Silver-glance is of a dark-blackish lead-grey colour, occurs usually massive, disseminated, in membranes, &c. and also chrystralized in cubes, octahedrons, garnet, dodecaedrons, and double eight-sided pyramids. Externally it is shining and glistering; internally it alternates from shining to glistering, and has a metallic lustre. It is soft, completely malleable, pretty flexible, and uncommonly heavy, containing upwards of 80 parts of pure silver; and is found in veins, along with native silver and other minerals, in Hungary, Austria, and other countries of Europe, but more particularly in Mexico and Peru.

Fourth species. Copper pyrites.

When fresh, its colour is brass-yellow, of different shades according to its richness. It occurs massive, disseminated in membranes, &c. and also chrystralized in various figures. Externally it is intermediate between glistering
and shining, internally soft; is between semihard and soft, brittle, easily frangible, and heavy.

Fifth species. White copper ore
Is of an intermediate colour between silver-white and bronze-yellow: occurs massive and disseminated; is internally glistening, with a metallic lustre; rather soft, brittle, easily frangible, and heavy. It is found in veins and mineral beds in primitive mountains, and is produced in Cornwall, in different parts of Germany, in Siberia, and in South America. Next to it is one of the rarest species of copper ore.

Sixth species. Grey copper ore, or Cold ore.
The most common colour is steel-grey: it occurs massive, disseminated, and also crystallized in tetrahedrons, octahedrons, and garnet dodecahedrons. It is more or less semihard, brittle, easily frangible, and heavy; and is found in the newer primitive rocks, and likewise in transitive and loact rocks in several mines of Cornwall, in Germany, Italy, Sweden, Norway, Siberia, and Chili. It is usually smelted on account of the copper it contains.

Seventh species. Copper black.
The colour is usually intermediate between bluish and brownish-black: it occurs massive, or disseminated; and as a coating, to other ores of copper; is always more or less cohering, and heavy, containing from 40 to 50 parts of copper. It is usually found with copper pyrites, &c., and is produced in Silesia, Germany, France, Sweden, Norway, and Siberia. Sometimes it is very beautiful.

Eighth species. Red copper ore.
Compact red copper is usually of a dark cobaltine-red colour: occurs massive, in membranes, crowded, amorphous, and also disseminated. Internally it is glistening, inclining to glistening, with a semimetallic lustre: it is opaque, semihard, brittle, easily frangible, and heavy.

Ninth species. Tile ore.
Earthly tile ore is usually of a red lividaceous colour: massive, disseminated, and inclining copper pyrites; is intermediate between friable and solid, soils slightly, is almost always cohering, and heavy. It is found in veins; commonly accompanied with native copper ore and malachite.

Tenth species. Copper azur.
Earthly copper azure is of a small-blue colour; usually friable, and disseminated; is composed of dusty particles, does not soil, is chiefly cohering, and approaches to heavy. It is found in small quantities, usually accompanied with malachite and copper green, in different parts of Germany, in Norway, and Siberia.

Eleventh species. Malachite, which see.

Twelfth species. Copper green.
The principal colour is verdigris-green, of different degrees of intensity: it usually occurs massive, disseminated, and coating malachite; is internally shining; more or less translucent, soft, not very brittle, easily frangible, and intermediate between heavy and non-precious heavy. It is found in the same geognostic situation with malachite, in Cornwall and other countries, but is rare.

Thirteenth species. Iron-shot copper
Earthly iron-shot copper green is usually of an olive-green colour: occurs massive, and disseminated; is dull, soils a little, soft, passing into friable, not very brittle, easily frangible, and not particularly heavy.

Fourteenth species. Copper emerald.
The colour is an emerald-green. It occurs in crystallized six-sided prisms, which are externally and internally shining, with a vitreous lustre. It is semihard, brittle, and not particularly heavy; and is found in the remoter parts of the Russian dominions, and on the Chinese frontiers.

Fifteenth species. Copper mica.
Is usually of an emerald-green colour: it occurs massive, disseminated, and occasionally crystallized in very thin six-sided tables. Externally it is smooth and splendent, internally shining with a pearly lustre. The massive varieties are translucent; the chrysocolla transparent. It is very brittle, not particularly heavy; and has hitherto been found only in veins in Cornwall, where it passes under the unscientific name of foliated arseniat of copper.

Sixteenth species. Lenticular ore.
The colour is usually deep green, sometimes passing into verdigris green. It occurs crystallized in small, flat, double, four-sided pyramids; is externally shining; translucent, soft, rather brittle, and very easily frangible. Hitherto it has been found only in Cornwall.

Seventeenth species. Oilstone ore.
Foliated olivine ore is of a perfect olive-green: seldom occurs massive, usually in drusy crusts, and in small crystals, presenting acute rhomboeds, and oblique four-sided prisms. Internally it is glistening, with an adamantine lustre. It is very soft, sectile, and heavy in a low degree; and has hitherto been found only in Cornwall.

Sixth Genus. Iron.

First species. Native iron.
Is of a light steel-grey colour, inclining to silver white: it has hitherto been found only in Russia; internally it is intermediate between glistening and glistening, with a perfect metallic lustre. It is between soft and semihard, perfectly malleable, common flexible, difficultly frangible, and uncommonly heavy. Hitherto it has been found only in loose masses on the surface of the earth, and is a rare production.

Common iron pyrites is usually of a perfect bronze-yellow colour: it occurs massive, disseminated, in membranes, and also crystallized in cubes, octahedrons, dodecahedrons, icosahedrons, and hexadecahedrons. It is hard, brittle, and heavy, and when rubbed or struck with steel, emits a strong sulphureous smell. It occurs in almost every kind of mineral repository, but most commonly in granite; its geographical distribution is equally extensive, but it is principally valued on account of the sulphur which may be extracted from it by sublimation.

Third species. Magnetic pyrites.
Is of an intermediate colour between bronze-yellow and copper-red: it occurs massive and disseminated; is generally shining, with a metallic lustre, passes from hard to semihard, is brittle, easily frangible, and heavy. It is attracted by the magnet; is found only in primitive mountains, in Cornwall, in several parts of Germany, in Norway, and Siberia; and is used for the same purposes as common pyrites.

Fourth species. Magnetic ironstone.
Common magnetic ironstone is of an iron-black colour: it is massive, disseminated, and also crystallized in cubes, octahedrons, and garnet dodecahedrons, and rectangular four-sided prisms. It is externally shining; internally between splendent and glistening, with a metallic lustre; is intermediate between hard and semihard, brittle, and heavy. It occurs most frequently in primitive mountains, and is found in the Shetlands, many parts of Germany, and other countries, particularly Sweden. When pure it affords excellent bar iron.

Fifth species. Iron glance.
Common iron glance is usually of a dark steel-grey colour, with several different shades. It commonly occurs massive and disseminated, and also crystallized in flat, double, three-sided pyramids, and in double three-sided pyramids, it alternates from splendent to glistening; internally it is most commonly glistening. It is hard, brittle, heavy, and rather difficulty frangible. It occurs in beds and veins in primitive and transitive mountains, and is found in considerable quantities in Sweden, and other countries, and affords, when smelted, an excellent mallable iron.

Sixth species. Red iron-stone.
Red iron stone is of a reddish-brown colour, and is frequently found in the carboniferous strata. It occurs in beds, and in veins, and is generally found in a compact, massive, and cohering state. It is hard, brittle, and heavy, and occurs in beds, and in veins, in various parts of Germany, and in Chili.
Nineth species. *Black iron-stone.*

Compact black iron-stone, is of an intermediate colour between bluish-black, and dark steel-grey; it occurs massive, tuberose, gemiform, &c, it is semihard, brittle, easily friable, and heavy.

Tenth species. *Clay iron-stone.*

Reddish is of a light brownish-red, passing into chestnut-brown; it usually massive, and friable, and writes, is sectile, easily friable, and rather heavy. It is chiefly found in the newer clay-late, and is produced rather abundantly in Germany and Siberia. The common varieties are used by the carpenter, the fitter by the painter, under the name of red-chalk.

Eleventh species. *Bag iron-ore.*

Morass ore is of a yellow-brown colour, sometimes friable, sometimes coherent, and occurs massive, corroded, in grains, and tubercous. It is very strongly, feels meagre, but soft.

Twelfth species. *Blue iron-ore.*

When fresh it is white, but soon becomes of an indigo-blue colour, of different degrees of intensity; it occurs massive, disseminated, and thinly coating; the particles are dull and dusty; it soils slightly, belts fine, and is lightish. It is in degrees of pyrite on clay-beds, and other situations, in the Sheland islands, Iceland, Sweden, and Siberia.

Thirteenth species. *Green iron-ore.*

Friable green-iron ore is of a sickly-green colour, occurs massive and disseminated, is more or less coherent, soft, fine, easily friable, and sectile, and is intermediate between particularly heavy and hard.

Fourteenth species. *Cube ore.*

The colour is olive-green, of different degrees of intensity; it occurs massive, and exhibits in small cubes, is translucent, soft, brittle, and not particularly heavy. It is found in veins, but hitherto only in Cornwall.

Seventh genus. *Lead.*

First species. *Lead glance.*

Common lead glance is of a fresh leady-grey colour, of different degrees of intensity; it occurs massive, disseminated, in membranes, &c, and also crystalized in crystals, octahedrons, four-sided prisms, six-sided prisms, and three-sided tables. It is soft, sectile, easily friable, and uncommanly heavy; and it is found in veins and beds in primitive, transvive, and floetz mountains, at lead-hills in Lanarkshire, Derbyshire, and several other counties of England, Scotland, and Wales; besides being widely diffused over other parts of the globe, it is most frequently worked as an ore of lead, but sometimes as an ore of silver.

Second species. *Blue-lead ore.*

It is of an intermediate colour between dark indigo-blue and lead-grey; it occurs massive, and crystalized in perfect six-sided prisms, is soft, sectile, easily friable, and heavy; and it is found in veins with other minerals of the same class, but is altogether a rare fossil, nor has it hitherto been discovered in Britain.

Third species. *Brown-lead ore.*

It is of a hair-brown colour of different degrees of intensity; it occurs massive, and exhibits in six-sided prisms, is freely translucent, soft, not very brittle, easily friable, and intermediate between heavy and uncommonly heavy; it is commonly associated with other minerals, in Bohemia, Hungary, Brittany, and Saxony.

Fourth species. *Black-lead ore.*

The colour is greyish-black, of different degrees of intensity; it occurs massive, disseminated, and exhibits in six-sided prisms, externally is usually splendent, internally shining with an adamantine lustre, is rather brittle, easily friable, and heavy. It is found in veins, and almost always accompanied with other kinds of lead ore, at lead-hills in Scotland, in Bohemia, Saxony, and other mineral countries.

Fifth species. *White-lead ore.*

The colour is white, but has various shades; it occurs massive, disseminated, in membranes, but most commonly crystalized in pyramids, and pyramids of different figures. Externally, it is scapolitic, splendent, internally between splendent and glistening, with an adamantine lustre. It is not, brittle, very easily friable, and heavy, and is found in most places where the other species occur, in England, Wales, Scotland, Ireland, &c. Next to lead glance it is the most common of the lead ores, but is seldom in sufficient abundance to become an object to the metalurgist.

Sixth species. *Green-lead ore.*

Its colour is grass-green, of various shades; it generally occurs crystalized, in six-sided prisms, is always translucent, soft, rather brittle, very easily friable, and heavy. It is produced in Scotland and other countries, and is sometimes confounded with the preceding species.

Seventh species. *Redlead ore.*

Its general colour is a hyacinth-red; it occurs massive but rarely, sometimes in membranes, but most commonly crystalized in boudoulo four-sided prisms, is both externally and internally splendent, very soft, between brittle and sectile, easily friable, and heavy. It is found in veins in gneiss and mica slate, accompanied with other fossils of the same kind, in Austria, Saxony, and Sibire, and on account of its beautiful colour is chiefly used as a pigment.

Eighth species. *Yellow-red ore.*

Its principal colour is wax-yellow; it is generally crystalized in rectangular four-sided tables, cubes, octahedrons, equilateral eight-sided tables, and double eight-sided pyramids. Externally, it is shining, and glistening; internally squamulose, with a resonant lustre; it is translucent, soft, between brittle and sectile, easily friable, and heavy. It is found in compact lime-stone in Cornwall, and some other countries of the continent.

Ninth species. *Lead vitriol, or vitriol of lead.*

The colour is yellowish-grey and greyish-white; it occurs only crystalized in octahedrons of different figures. Externally it is shining, internally splendent, with an adamantine lustre. It is often semi-transparent, rather brittle, and heavy, and is found in Scotland, Anglesc, and Spain.

Tenth species. *Lead earth.*

Coherent lead earth is usually of a yellowish-grey colour; it occurs massive, is internally glowing, usually opaque, soft, firmly clining to se-tile, easily friable, and heavy. It is found in primitive lime-stone in Derbyshire, Scotland, and many other countries.

Eighth genus. *Tin.*

First species. *Tin pyrites.*

The colour is intermediate between steel-grey and brass-yellow; it occurs massive and disseminated. Internally it is glistening, and has a metallic lustre, is semihard, brittle, easily friable, and heavy. It melts easily, and has hitherto been found only in Cornwall.

Second species. *Tin stone.*

The most common colour is blackish-brown; it occurs massive, disseminated, in rolled pieces, in grains, like sand, but most frequently crystalized in prisms and pyramids of different figures. Internally it is shining and glistening, it yields a greyish-white streak, is hard, easily friable, brittle, and very heavy. It is found only in primitive rocks, and is confined to a few situations, like all the tin genus.

Third species. *Cornish tin ore, or wood tin.*

The most usual colour is hair-brown, of different degrees of intensity; it occurs usually in rolled pieces, sometimes reniform with impressions. It is found usually in large and coarse granular distinct concretions, is opaque, hard, brittle, easily friable, and uncommonly heavy. It is inflexible, and hitherto has only been found in Cornwall in alluvial land, accompanied with tin stone.

Ninth genus. *Bismuth.*

First species. *Native bismuth.*

Its colour is silver-white, with an inclination to red; it occurs massive, disseminated in leaves, recellularized, and crystalized in small four-sided tables, and in small and distinct cube, and three-sided pyramids. It is soft, sectile, rather difficultly friable, and commonly heavy; and is found in veins in primitive mountains in Saxony, and other parts of the continent; but it is doubtful if produced in Britain.

Second species. *Bismuth glance.*

The colour is a light lead-grey; it occurs massive, disseminated, and in acicular and capillary crystals; it soils, inclines to sectile, is easily friable, and heavy. It is found always in veins, and is usually accompanied with native bismuth, chiefly in Saxony, Bohemia, and Hungary.

Third species. *Bismuth-ochre.*

The colour is a straw-yellow, passing into other yellow shades of the same species; it occurs massive and disseminated, opaque, soft, not very brittle, easily friable, and heavy. This mineral is rare, and seems to be confined to a few places in Saxony and Bohemia.

Tenth genus. *Zinc.*

First species. *Blende.*

Yellow blende is of a dark wax and sulphur yellow colour; it usually occurs massive and disseminated, but is sometimes crystalized in rectangular four-sided prisms; it is shining and splendent both externally and
MINEALOGY.

Sixth species. Antimonio-ochre.
The colour is a straw-yellow, of various degrees of intensity; it seldom occurs massi-}

evated, and disseminated, but usually as a coating on chrysolite or red antimony ore. It 

dull, soft, not very brittle, nor particularly heavy. It is found always in veins, in differ-

cent parts of Germany, and is evidently found by the decomposition of grey anti-

mony. It is found in veins in Bohemia, Hungary, and Saxony.

Twelfth Genus. Cobalt.

Third species. Cobalt glance.
The colour is a silver-white, slightly inclin-

ing to reddish; it is commonly massive and 

disseminated, sometimes chrysoellized in dif-
erent forms; it is externally splendid, inter-

nally between shining and glistening, and has 

a metallic lustre. It is semihard, brittle, 

not very easily frangible, and heavy. It easily melts 

before the blowpipe, emits a strong arsenical 

smell, and yields a white metallic globule.

Fourth species. Black cobalt ore.
Earthly black cobalt ore is of an interme-

ciate colour between brownish-black and blue-

black, is composed of dust, dusty particles, 

which soil a little, usually cohering, streak 

shining, and very fine granular and distinc-

concretions, is semihard and brittle, and not 

difficult to separate, and heavy. Before 

the blowpipe it emits an arsenical smell and 

colour, and afterwax melts, though with 

difficulty. It is found in Cornwall, Norway, 

and many other countries, and is nearly al-

lied to cobalt.

It is of a apple-green colour, occurs always 
as a coating or efflorescence, is composed of 
dust dusty particles, loose, or little cohering, 
feels meagre, and is light. It is found in the 
same situations with other species. It is 

not certain that native nickel has yet been 
discovered, though it is mentioned by some 

mineralogists.

Fourthteen Genus. Manganese.

First species. Grey manganese ore.
Radiated grey manganese ore is of a dark 

steel-grey colour, occurs massive, dissemi-
nated, and chrysoellized in prisms of different 

varieties. It is found in coarse, large, and 

small granular distinct concretions; soils 

strongly when rubbed, is soft, brittle, rather 
difficulty frangible, and not particularly 

heavy. It is found in several counties of 

England and Scotland, and in different part of 

Germany.

First species. Coppernickel.

It occurs frequently in various grey coatings, 

and disseminated, is feebly glistening, bor-

ering on dull, scarcely soils, has a shining 

streak, and is very soft and light.

Sixth species. Red cobalt ochre.

Cobalt ochre is of a peach blossom-red co-

lour, of different degrees of intensity, occurs 
massively in veins, with grey coatings, and 
disseminated, is feebly glistening, bor-

erling on dull, scarcely soils, has a shining 

streak, and is very soft and light.

Third species. Coppernickel.

It is of a red copper-colour of different de-

grees of intensity; it occurs usually massive 

and disseminated, is internally glistening, and 

has a metallic lustre. It is usually unsepa-

rated; sometimes, however, it is found in 
coarse and small granular distinct concre-
tions, is semihard in a high degree, brittle, 

not very easily frangible, and heavy. Before 

the blowpipe it emits an arsenical smell and 
colour, and afterwards melts, though with 
difficulty. It is found in Cornwall, Norway, 

and many other countries, and is nearly al-

lied to cobalt.

It is of a apple-green colour, occurs always 
as a coating or efflorescence, is composed of 
dust dusty particles, loose, or little cohering, 
feels meagre, and is light. It is found in the 
same situations with other species. It is 

not certain that native nickel has yet been 
discovered, though it is mentioned by some 

mineralogists.

Fourteenth Genus. Manganese.

First species. Grey manganese ore.
Radiated grey manganese ore is of a dark 

steel-grey colour, occurs massive, dissemi-
nated, and chrysoellized in prisms of different 

varieties. It is found in coarse, large, and 

small granular distinct concretions; soils 

strongly when rubbed, is soft, brittle, rather 
difficulty frangible, and not particularly 

heavy. It is found in several counties of 

England and Scotland, and in different part of 

Germany.

Second species. Black manganese ore.

Is of an intermediate colour between brownish-black and blue-black, oc-

urs massive, disseminated, and in octahedral 

chrysals. It is found in small and fine gra-

ular concretions, is opaque, semihard, brittle, and heavy; but is a rare mineral, 

and hitherto found only in a few places of 

Germany and Spain.

Third species. Red manganese ore.

Is of a light rose-red colour, occurs massive and dissemi-
nated, is internally dull, translu-
cent in a slight degree, hard, brittle, easily frangible, and heavy. It is found in veins in 

Norway, France, and some other countries.

Fifteenth Genus. Molybdena.

First species. Molybdena.

Its colour is a fresh burning lead-grey; it 
occur usually massive and disseminated, but also chrysoellized in six-sided tablets, and 

short six-sided prisms; internally it is splen-
dent, the fracture perfectly foliated, and is 

found in large and coarse granular distinct 
concretions. It soils a little, is very soft, 
easily frangible, its thin leaves common flexi-

tle, feels grossy, and is heavy. It is one of 

the oldest of metals, and occurs only in 

primitive mountains, disseminated, or in 

veins; and is produced in Norway, Sweden, 

Bohemia, and other countries.
MINERALOLOGY.

SIXTEENTH GENUS. Arsenic.

First species. Native arsenic.

When fresh broken, it is of a light yellowish lead-grey colour, but it quickly parishes; it occurs massive, disseminated, reniform, and in plates, with various impressions. It is found in thin, curved, bimetallic, distinct concretions; in the streak it becomes shining and metallic, semihard in a high degree, very easily frangible, and between sectile and malleable. It occurs only in primitive mountains, and in veins of a newer formation, and is found in various parts of Germany, in France, and in Chili.

Second species. Arsenic pyrites.

Common arsenic pyrites is, when fresh, of a silver-white colour, but soon acquires a yellowish tarnish; it occurs massive, disseminated, and also in crystals of various figures. Internally, it is shining, with a metallic lustre; and is found usually unseparated, stard, brittle, not easily frangible, and heavy. It occurs only in primitive mountains and in beds, and is produced in Norway, Germany, Bohemia. From this ore the white oxide of arsenic is principally obtained.

Third species. Orpiment.

Red orpiment is of an aurora-colour, of different degrees of intensity: it occurs massive, disseminated in membranes, and also chrysalitzed in oblique four-sided and six-sided prisms. It is transparent, but the crystals are transparent, is very soft, yields a lemon or orange-coloured streak, and is easily frangible. It is found both in primitive and floetz mountains, and is produced in Germany, France, Italy, and the West Indies. It is used as a pigment.

Yellow orpiment is of a perfect lemon-yellow colour, occurs massive, and in very minute crystals, is found in large, coarse, and small angular granulated distinct concretions, is translucent, very soft, sectile, and common flexible. It occurs principally in floetz mountains, in several parts of Germany and the East.

Fourth species. Arsenic brome.

The colour is a reddish-white and snow-white; it occurs as a coating, in small balls, &c. and in very delicate capillary shining crystals, is translucent on the edges, very soft, easily frangible, and soils. It is produced in rents of a granite rock, and hitherto has only been discovered in Swabia.

SEVENTEENTH GENUS. Scheele.*

First species. Tungsten.

The colour is usually yellowish and greyish-white, which pass into several other neighboring shades; it occurs massive, disseminated, and frequently chrysalitzed. Internally it is shining, with a vitreous lustre; is more or less translucent, soft, not very brittle, and uncommonly heavy; yields a yellow or yellowish-grey streak. It is found in primitive mountains, and belongs to the oldest metamorphic formations, and is produced in Cornwall, Sweden, Saxony, and Bohemia.

Second species. Wolfram.

Is of an intermediate colour between dark greyish-black, and brownish-black; it occurs massive, and also chrysalitzed in broad six-sided prisms, and rectangular four-sided tables; and is found in fortification-wise curved bimetallic distinct concretions. It is opaque, yields a reddish-brown streak, is soft, brittle, and uncommonly heavy. It is produced in the primitive mountains, almost always accompanied with tin, in Cornwall, and some other countries.

EIGHTEENTH GENUS. Menachine.

First species. Menachpine.

Is of a greyish-black colour, inclining to iron-black, occurs only in small flattish angular grains. Internally is glistening, with an adamantine lustre, is perfectly opaque, soft, brittle, retains its colour in the streak, is easily frangible, and moderately heavy. It is attractable by the magnet, and is found in Cornwall, accompanied by fine quartz-sand, in the isle of Providence in America, and at Botany Bay.

Second species. Orpiment.

Is of a dark red-brown colour, of various degrees of intensity; it occurs always chrysalitzed, and that in very acute octahedrons. It is chiefly translucent, and semitransparent, sectile, brittle, and borders on heavy. It is found in Dauphiny, and appears from accurate experiments to be an oxide of menachine mixed with silica.

Third species. Rutile.

Is of a dark blood-red colour, of various degrees of intensity; it occurs always chrysalitzed in four-sided and six-sided prisms, and in compressed acicular and capillary crystals. Externally it is shining, internally splendent, translucent in a slight degree, hard, easily frangible, and not very heavy. It is found imbedded in drusy cavities of granite, &c. in different parts of Germany, France, Spain, Siberia, and South Carolina.

Fourth species. Nigrine.

Is of a dark brownish-black colour, passing to velvet-black; it occurs in larger and smaller angular grains, and in rolled pieces. Externally moderately glittering, internally the same, with an adamantine lustre, is opaque, sectile, hard, and yields a yellowish-brown streak. It is found in alluvial hills in several parts of Germany, and also in Ceylon.

Fifth species. Irisine.

Is of an iron-black colour, somewhat inclining to brownish-black; it occurs usually in small oblique angular grains, and in rolled pieces, internally glistening, with a semimetallic lustre, is completely opaque, hard, brittle, and retains its colour in the streak. Hitherto it has been found only in the stream of the river in Germany, from which it receives its appellation. It bears a great resemblance to iron-sand.

NINETEENTH GENUS. Uran.

First species. Pitch ore.

Is usually of a velvet-black colour; it occurs almost always massive and disseminated, is uncommonly heavy, and completely infusible without addition. It is found in veins of primitive mountains along with lead and silver ores, and is produced in Saxony and Norway.

Second species. Uran mica.

The principal colour is a grass-green, passing into various allied shades; it occurs sometimes in membranes, but commonly chrysalitized in rectangular four-sided tables. It has a fracture which is followed, the fragments and distinct concretions are too minute to be determined. It is more or less translucent, soft, sectile, easily frangible, and is found in iron-stone veins in Cornwall, Saxony, and France.

Third species. Uran ochre.

Fribale uranium or ochre is usually of a straw-yellow colour; it generally occurs as a coating or efflorescence on pitch ore; is friable, and composed of dull dusty particles, which feel meagre, and are not particularly heavy.

Indurated uranium or ochre is of the same colour as the preceding; occurs massive and disseminated, is generally dull, internally opaque, soft, brittle, and soils a little, and is found along with the other ores of uranium.

TWENTIETH GENUS. Sylcom.

First species. Native sylcom.

Is of an intermediate colour between white and silver-white: it occurs massive and disseminated, and also chrysalitized in four and six-sided prisms, in small three-sided pyramids, in cubes, and in short acicular crystals. It is soft, not very brittle, easily frangible, and heavy; and before the blowpipes melts as easily as lead, burning with a light green colour, and emitting a sharp, disagreeable colour. Hitherto it has only been found at Face-bay, in Transylvania.

Second species. Graphite ore.

Its colour is a light steel-grey; it occurs massive and chrysalitized; externally is splendent, internally glistening. When massive, it shows a tendency to fine granular distinct concretions; it is soft, brittle, sectile, and heavy, and is worked as an ore of gold in Transylvania, where alone it has yet been found.

Third species. Yellow Sylcom ore.

Is of a silver-white colour, inclining to brass-yellow: it occurs disseminated, and chrysalitized in very small and rather broad four-sided prisms, soft, rather friable, and uncommonly heavy. It is found along with the other species of the genus, and contains a considerable portion both of gold and silver.

Fourth species. Black Sylcom ore.

Is of an intermediate colour between iron-black and blackish lead-grey; it occurs massive, and in small, thin, and longish six-sided tables, which are usually imbedded. Externally it is splendent; internally shining, soils a little, is very soft, sectile, splits easily, and in thin leaves is common flexible. It melts easily before the blowpipe; occurs in veins filling with other minerals, but is only found in Transylvania, where it is worked for; the gold and silver it contains.

TWENTY-FIRST GENUS. Chrome.

First species. Acicular, or Needle ore.

Its colour is dark steel-grey; occurs in innumerable dazides, and is commonly imbedded with a metallic lustre, is soft, not very brittle, heavy, and is always accompanied with chrome ochre, and sometimes with native gold. It is found in Siberia.
Second species. Chrome Ochre.

Mint. See Mentha.

MIN. 8. See Mentha.

27. Octahedron, with bevelled angles. By Auction Bon.

28. Cube, with the angles acuminated by three planes which are set on the lateral planes.

29. Cube, with the angles acuminated by three planes which are set on the lateral planes.

30. Rectangular four-sided prism acuminated by four planes, which are set on the lateral planes.

31. Equiaangular six-sided prism acuminated by both extremities by six planes, which are set on the lateral planes.

32. Four-sided prism, acuminated on both extremities by four planes, which are set on the lateral edges.

33. Six-sided prism, acuminated on both extremities by three planes, which are set on the alternate lateral edges.

34. Six-sided prism, acuminated on both extremities by three planes, which are set on the alternate lateral edges.

35. Double eight-sided pyramid, acuminated on both extremities by four planes, which are set on the alternate lateral edges.

MINIMUM, in the higher geometry, the least quantity attainable in a given case.

MINOR, in law, is an heir, either male or female, before they arrive at the age of twenty-one; during the minority of such, they are usually incapable of acting for themselves.

MINOR, in logic, the second proposition of a regular syllogism.

MINOR, in music, signifies less, and is applied to certain concords or intervals which differ from others of the same denomination by half a tone; thus we say a third minor, meaning a less third; a sixth major and minor.

MINT, the place in which the public money is coined. See COINING.

The officers of the mint are, 1. The warder of the mint, who is chief; he oversees the other officers and receives the bullion, 2. The master worker; who receives the bullion from the warder, causes it to be melted, delivers it to the moneymen, and when it is coined, receives it again. 3. The compounder, who is the overseer of all the moneymen, and sees that all the money is made to the just assay. 4. The assay-master; who weighs the gold and silver, and sees that it is according to the standard. 5. The assayer, who takes the accounts. 6. The surveyor of the melting; who, after the assay-master has made trial of the bullion, sees that it is cast out, and not altered after it is delivered to the melter. 7. The engraver, who graviates the stamps and devices for the coinage of the money. 8. The clerk of the issues, who sees that the issues are current and fit to work with. 9. The moneymen; who receive the bullion before it is coined. 10. The provost of the mint; who provides for, and oversees all the moneymen. 11. The blanckers; who anneal and clean the money. 12. The moneyers; some of whom forge the money, some shear it, some round and mill it, and some stamp or cut it. 13. The porters, who keep the gate of the mint.

MINUA STIA, a genus of the triandra trignia class and order. The cal. is 5-leaved; cor. none; caps. 1-celled, 3-valved. There are five styles, herbs of Spain.

MINUTIUS, in geometry, the sixtieth part of a degree of a circle.

Minutes are denoted by one acute accent, thus (9); as the second, or sixtieth part of a minute, is by two such accents, thus (9); and the third by three, thus (9).

Minutes of time, the sixtieth part of an hour.

MIRABILIS, marvel of Peru; a genus of the monoqorn order, in the pentandria class of plants, and in the natural method ranking with those of which the order is doubtful. The corolla is funnel-shaped above; the calyx inferior, the nectarian globular, containing the gymnos. The most remarkable species are, 1. The jalapa, or common marvel of Peru. Of this there are varieties, with white flowers, with yellow flowers, with purple flowers, with red flowers, with white and yellow flowers, purple and yellow flowers, red and yellow flowers. 2. The lungwilla, or long-flowered mirabilis, with all the branches and shoots terminated by white flowers in clusters, having very long tubes, budding downward. 3. The dichtoma, dichotoma, or forked mirabilis, with smallish red flowers at the axillas, singly and close-sitting.

The roots of all these plants are purgative; but require to be given in a small quantity to operate equal to the true jalapa, which is a species of convolvulus. See CONVOLVULUS.

MIRROR, a speculum, looking-glass, or any polished body, whose use is to form the images of distinct objects by reflection of the rays of light.

Mirrors are either plane, convex, or concave. The first sort reflects the rays of light in a direction exactly similar to that in which they fall upon it, and therefore represents bodies of their natural magnitude. But the convex ones make the rays diverge much more than before reflection, and therefore exhibit to view the images of those objects which they exhibit; while the concave ones, by collecting the rays into a focus, not only magnify the objects they shew, but also burn very fiercely when exposed to the rays of the sun; and by them, a burning mirror.

In ancient times the mirrors were made of some kind of metal; and from a passage in the mosaic writings we learn, that the mirrors used by the Jewish women, were made of brass; a practice doubtless learned from the Egyptians.

Any kind of metal, when well polished, will reflect very powerfully; but of all others, silver reflects the most, though it has always been too expensive a material for common use. Gold is also very powerful; and all metals, or even wood, gilt and polished, will act very powerfully as burning mirrors. Even polished ivory, or straw nicely plaited together, will form mirrors capable of burning, if on a large scale.

Some of the more remarkable laws and phenomena of plane mirrors are as follow:

The spectator will see his image of the same size, and erect, but reversed as to right and left, and as far beyond the specular as he is before it. As he moves to or from the
speculum, his image will, at the same time, move towards or from the speculum also on the other side. In like manner if, while the spectator is at rest, an object be in motion, its image behind the speculum will be seen to move at the same rate. Also when the spectator moves, the images of objects that are at rest will appear to approach or recede from him, after the same manner as when he moves towards real objects.

2. If several mirrors or several fragments or pieces of mirrors, be all disposed in the same plane, they will only exhibit an object once.

3. If two plane mirrors, or speculars, meet in any angle, the eye, placed within that angle, will see the image of an object placed within the same, as often repeated as there may be perpendiculars drawn determining the places of the images, and terminated without the angle. See Optics.

MISCHINA, or MISINA, the code or collection of the civil law of the Jews. The Jews pretend, that when God gave the written law to Moses, he gave him also another not written, which was preserved by tradition among the rabbis. This, till rabbi Judah, surmised the Holy, seeing the danger they were in, through their dispersion, or departing from the traditions of their fathers, judged it proper to reduce them to writing.

The misna is divided into six parts: the first relates to the distinction of seeds in a field, to trees, fruits, tythes, &c. The second regulates the manner of observing festivals; the third treats of women, and matrimonial cases; the fourth of losses in trade, &c. The fifth is on obligations, sacrifices, &c. and the sixth treat of the several sorts of purification. See Talmud.

MISDEMEANOUR. A crime or misdemeanor is an act committed or omitted, in violation of a public law, either forbiolding or commanding it.

MISLETIE. See Viscum.

MISNOMER, the using of one name for another.

Where a person is described so that he may not be certainly distinguished and known from other persons, the omission, or in some cases, of the name shall not avoid the grant. 11 Rep. 20.

If the christian name is wholly mistaken, this is regularly fatal to all legal instruments, as well declarations and pleadings as grants and obligations.

The mistake of the surname does not vitiate, because there is no repugnancy that a person shall have different surnames; and therefore, if a man enter into an obligation by a particular name, it is implied that the same name in the deed, and his real name brought in by an alias; and then the name in the deed he cannot deny, because he is estopped to say any thing contrary to his own deed. 12 R. & A. 146.

MISPRISION, is generally understood to be of all such high offences as are under the degree of capital, but bordering thereon, and it is said that a misprision is contained in every treason and felony whatever, and that if the kind of plea, or the offender may be procured against for the misprision only. 4 Black. 119.

MIS-RECEITAL, in deeds, is sometimes injurious, and sometimes not, if a thing be referred to time, place, and number, and that is mistaken, all is void.

MITCHELLA, a genus of the trumonion monogynia class and order. The cor. is 1-petalid; stigmas 4; berry trid, 2-seeded. There is 1 species, an herb of N. America. MITCHELLA, a small shrub, equal to about one third part of a farthing. It also denotes a small weight used by the moneyers. It is equal to the twentieth part of a grain, and is divided into twenty-four lots.

MITE. See ACARUS.

MITELLA, bastard American sanicle: a genus of the digynia order, in the decanaria class of plants; and in the natural method ranking under the 13th order, succulent. The calyx is quinqued, the corolla pentapetalid, and inserted into the calyx; the petals planifid; the capsule unilocular and bivalved, with the valves equal. There are two species, both natives of North America, rising with annual herbaceous stalks from five to six or eight or nine inches in height, and producing spikes of small whitish flowers, whose petals are fringed on their circumference.

MITHRIDATEA, a genus of the monandria monogynia class and order. The cat. is four-foil; cor. none; fruit globular, depressed. There is one species, a tree of Madagascar.

MITHIMUS, a writ by which records are transferred from one court to another. This word is also used for the precept directed to a gaoler, under the hand and seal of a justice of the peace, for the receiving and safe keeping a felon, or other offender, by him committed to gaol.

MIZEN, in the sea-language, a particular mast or sail. The mizen-mast stands in the sternmost part of the ship. Its length is by some accounted the same with the height of the main-topmast, from the quarter-deck; or half the length of the mainmast, and half as thick. The sail which belongs to the mizen-mast is called the mizen-sail: and when the word mizen is used at sea, it always means the sail.

MINAS, a genus of the hexandria monogynia class and order. The cat. is 1-leaved, 3-parted; cor. 1-petalid, 3-parted; anthera 4-longercor; germ 3-lobed; stigma 3.

MINAS, a genus of the hexandria monogynia class and order. The cat. is 4-parted, superior; cor. none; seed 1. There is one species, an herb of New Zealand.

MINIUM, a genus of the mineral order of musel, belonging to the cryptogamia class of plants. The anthera is opeculated; the calyptra smooth, the female capitulum naked and powdery, remote. There are 24 British species, but none have any remarkable property except the two following: 1. The fontanum is an elegant moss, frequent in bogs, and on the borders of cold springs. It is from two to four inches high; the stems simple at the base, and armed with a rusty down; but higher up are red, and divided into several round, single, taper branches, which proceed nearly from the same point. The leaves are not more than fifth of an inch long, lanceolate and acute, of a whitish-green colour, and so thinly set, that the red stalk appears between them. This moss, as it may be seen at a considerable distance, is a good mark to lead to the discovery of clear and cold springs. Dr. Withering informs us, that it never grows near the banks of the second or third, has its tips inversely egg-shaped, nodding, and bright yellow. If the fruit-stalk is moistened at the base with a little water or steam, the head makes three or four revolutions; if the head is moistened, it turns back again.

MOAT, or DRICH, in fortification, a deep trench dug round the rampart of a fortified place, to prevent surprizes.

The brink of the moat, next the rampart, is called the scarpe; and the opposite one, the counterscarpe.

A dry moat round a large place, with a strong garrison, is preferable to one full of water, because the passage may be disputed inch by inch; and the besiegers, when lodged in it, are continually exposed to the bombs, shot, stones, and other missiles, which are thrown incessantly from the rampart into their works. In the middle of dry moats there is sometimes another small one, called a cuttice; which is generally dug so deep, till they find water to fill it. The deepest and broadest moats are counted the best, but a deep one is preferable to a broad one: the ordinary breadth is about twenty fathoms, and the depth about sixteen.

To drain a moat that is full of water, they dig a trench deeper than the level of the water, to let it run off; and then throw hurdles upon the mud and slime, covering them with earth or bundles of rushes, to make a sure and firm passage.

MODE, in logic, called also syllogistic mood, a proper disposition of the several propositions of a syllogism, in respect of quantity and quality.

As in all the several dispositions of the middle term, the propositions of which a syllogism may be either universal or particular, affirmative or negative; the due determination of these, and putting them together, according to any disposition of the middle term, in order to arrive at a just conclusion. There are two kinds of moods, the one direct, the other indirect.

The direct mood is that wherein the conclusion is drawn from the premises directly and immediately. "Every animal is a living thing, every man is a living animal; therefore every man is a living thing." There are fourteen of these direct moods, four of which belong to the first figure, four to the second and six to the third. They are denoted by so many artificial words framed for that purpose, viz. 1. Barbarum, or darth, darf, ferique. 4. Baralia, cebat, dabbis, fapiamo, friseon. 2. Cesare, camastures, fessio, harno. 3. Durapi, felapton, dia-
Mold, in music, a particular system, or collection of notes, by which the octave is divided into certain intervals, according to the genus. The doctrine of the antients respecting modes is rendered somewhat obscure, by the difference among their authors in the definitions, divisions, and names of their modes. Some place the specific variations of modes, or modes, in the manner of division, or order of the concentric parts; and others merely in the different tension of the whole: i.e., as the whole series of notes are more acute or grave, or as they stand higher or lower in the great scale of sounds.

Model, in a general sense, an original pattern, proposed for any one to copy or imitate. This word is particularly used in building for an artificial pattern made in wood, stone, plaster, or other matter, with all its parts and proportions, in order for the better conducting and executing some great work, and to give an idea of the effect it will have in large. In all great buildings, it is the most surest way to make a model in relief, and not to trust to a bare design or draught. There are also models for the building of ships, &c. and for extraordinary circumstances.

They also use models in painting and sculpture; whence, in the academies, they give the term model to a naked man or woman, disposed in several postures, to afford an opportunity to the scholars to design him in various views and attitudes.

Models in imitation of any natural or artificial substance, are most usually made by means of moulds composed of plaster of Paris. For the purpose of making these moulds, this kind of plaster is much more fit than any other substance, on account of the power it has of absorbing water, and soon condensing into an hard substance, even after it has been rendered so thin as to be of the consistence of cream. This happens in a shorter or longer time, as the plaster is of a better or worse quality; and its good or bad properties depend very much upon its age, to which, therefore, particular regard ought to be had. It is sold in the shops at very different rates, being made use of for casts, and the middling sort for moulds. It may be very easily coloured by means of almost any kind of powder excepting what contains an alkaline salt; for this would chemically decompose the substance of it, and render it unfit for use, the gypsum of plaster being a substance which would alone be composed by the alkalies of the lime. A very considerable quantity of chalk would also render it soft and useless, but too hard to have its great degree. The addition of common salt is like to render it much harder than if mere water is made use of. In making either moulds or models, however, we must be careful not to make the mixture too thick at first; for if this is done, and more water added to this, the composition must always prove brittle, and of a bad quality.

The particular manner of making models (or casts, as they are also called) depends on the form of the subject to be taken. The process is easy where the parts are elevated only in a slight degree, or where they form only a right or obtuse angle with the principal surface from which they project; but where the parts project in smaller angles, or form curves in the upper surface, the work is more difficult. This observation, however, holds good only with regard to hard and inelastic bodies; for such as are soft may often be freed from the mould, as though they themselves were not mentioned. But though this is the case with the soft original substance, it is not so with the inflexible model when once it is cast.

The moulds are to be made of various designs. To make the case of the model to be cast; and may be from half an inch to an inch, or, if very large, an inch and a half. Where a number of models are to be taken from one mould, it will likewise be necessary to have it of a stranger texture than where only a few are required for very obvious reasons.

It is much more easy to make a mould for any soft substance than a rigid one, as in any of the viscera of the animal body; for the fluidity of that substance makes it easily accommodate itself to the projecting parts of the substance; and as it is necessary to inflate these substances, they may be very easily extracted again, by letting out the air which distends them.

When a model is to be taken, the surface of the original is first to be greased, in order to prevent the plaster from sticking to it; but if the substance itself is slippery, it is the case with the internal parts of the human body, this need not be done: when necessary, it may be laid over with limed oil by means of a painter's brush. The original is then to be laid on a smooth table, previously greased, or covered with a cloth, to prevent the plaster sticking to it; then surround the original with a frame dipped in the putty, at such a distance from it as will admit the plaster to rest upon the table on all sides of the subject for about an inch, or as much as is sufficient to give the proper degree of strength to the model. A sufficient quantity of plaster is then to be placed as uniformly as possible over the whole substance, until it is everywhere covered to such a thickness as to give a proper substance to the mould, which may vary in proportion to the size. The whole must then be suffered to remain in this condition till the plaster has attained its hardness; when the frame is taken away, the mould may be inverted, and the subject removed from it; and when the plaster is thoroughly dry, let it be well scour.

Having formed and seasoned the moulds, they must next be prepared for the casts by greasing the inside of them with a mixture of olive oil and lard in equal parts, and then filled with fine plastic, and the plane of the mould formed by holding the surface of the table, covered to a sufficient thickness with coarse plaster, to form a strong basis or support for the cast where this support is requisite, as is particularly the case where the thin and membranous parts of the body are to be represented. After the plaster is poured into the mould, it must be suffered to stand until it has acquired the greatest degree of hardness it will receive; after which the mould must be removed: but this is attended with some difficulty when the shape of the subject is unapproachable; and in some cases the mould must be separated by means of a small mallet and chisel. If this method does not procure any parts of the model should be broken on in the mould, it may be rendered somewhat stronger by making the two surfaces to be applied to each other quite wet; then interposing between them a little liquid plaster; and lastly, the joint smoothed, after being thoroughly dry, by small brushes made in the mould can be filled up with liquid plaster, after the sides of them have been thoroughly wetted, and smoothed over with the edge of a knife.

In many cases it is altogether impracticable to make a mould of one piece for a whole subject; and therefore it must be considered how this can be done in such a manner as to divide the mould into the fewest pieces. This may be effected by making every piece cover as much of the pattern as possible, without surrounding such projecting parts, or running into such hollows as would not admit a separation of the mould. Where any internal pieces are required, they are to be made in the outer pieces, after the former have become hard.

Besides the models which are taken from inanimate bodies, it has been frequently attempted to take the exact resemblance of people while living, by using their face as the pattern to be made in a mould; and the operation, however disagreeable, has been submitted to by persons of the highest rank in life. A considerable difficulty occurs in this, however, from the person's being apt to shrink and distort his features when the liquid is poured upon him; neither is he altogether without danger of suffocation, unless the operator well understands his business.

To avoid the former inconvenience, it will be proper to mix the plaster with warm instead of cold water, by which means the person will be under no temptation to shrink; and to prevent any danger of a fatal accident, the following method must be practised: The subject is to lie on his back, the head must first be raised by means of a pillow to the exact position in which it is naturally carried when the body is erect; then the parts to be represented must be very thinly covered over with flour of almonds, by means of a painter's brush; the
The nose is then to be first covered with fine fluid plaster, beginning at the upper part of the foremost lip, or nostrils, which are to be kept close, that the plaster may not come in contact with the globe; yet, not closed so strongly as to cause any unnatural wrinkles. Cover then the nose and ears, pushing first up the meatus and with conical, and the nostrils with a small quantity of tow rolled up, of a proper size to exclude the plaster. During the time that the nose is thus stopped, the person is to breathe through the mouth; in this state the fluid plaster is to be brought down low enough to cover the upper lip, observing to leave the roll of tow projecting out of the plaster. When the operation is thus far carried on, the plaster must be covered to harden; after which the tow may be withdrawn, and the nostrils left free and open for breathing. The mouth is then to be closed in its natural position, and the plaster brought down to the extremity of the chin. Begin then to cover that part of the breast which is to be represented, and spread the plaster to the outsides of the arms and upwars, in such a manner as to meet and join that which is previously laid on the face: when the whole operation has acquired its pliable consistence, it is to be cautiously lifted, without breaking or giving pain to the person. After the mould is constructed, it must be seasoned in the manner already directed; and when the case, it is to be separated from the model by means of a small mallet and chisel. The eyes, which are necessarily shown closed, are to be carved, so that the eye-lids may be represented in an elevated posture; the nostrils hollowed out, and the back part of the head, from which, on account of the hair, no mould can be taken, must be finished according to the skill of the artist. The edges of the model are then to be neatly smoothed off, and the bust fixed on its pedestal.

MODULATION, in music, the art of conducting harmony, in composition, or temporary performance, through those keys and modes which the rule of art, or fundamental, or original key. Though every piece, as is well known, has its principal or governing key, yet, for the sake of contrast and relief, it is not only allowable but necessary that it be sometimes thrown from mode to mode; to assume different sharps or flats, and lead the ear through those transitions of tone and harmony which interest the feelings and delight the ear. But though in grand compositions there is no quality of a greater importance than that of a masterly modulation, it is not easy to lay down rules for its accomplishment. Sometimes a gradual and almost insensible evolution of harmony is requisite to the composer's object; at other times, a bold and sudden change can alone produce the necessary effect.

MODULAR ARCHITECTURE. MODUS DECIMANDI, in law, is where money, land, or other valuable consideration, has been given, true out of mind, to the minister or parish of any certain place, in the room of tithe. A clergyman may sue in a spiritual court for money, land, goods, chattels that is depicted there, or a custom is to be tried, the trial thereof belongs to the courts of common law. When lands are converted to other uses, as in the case of hay-ground turned into tillage, the tithe may be discharged, and the tithes paid again in kind.

MOERHINGIA, mossy chickweed, in botany, a genus of the oxtidria digynia class of plants, the flower of which is composed of four short, undivided petals; and its fruit is a subglabrous capsule, with one cell, in which are contained numerous roundish seeds. There is one species.

MOLE. See ZAPPA.

MOLLUGO, African chickweed; a species of the tryginess order, in the triandria class of plants; and in the natural method ranking under the 24th order, carycophylii. The calyx is pentaphyllous; there is no corolla; the capsule is trilocular, and trivalved. There are six species, annuals of the Cape, and of the E. and W. Indies.

MOLUCCELLA, in botany, a genus of the dicynthium-gynaec-petumpia class of plants, the flower of which is monopetalous and labi-ated; the upper lip being entire, and the lower one divided; the seeds are turbinated, and contained in the bottom of the cup. One annual species.

MOLYBDATAS. These salts, composed of molybdic acid combined with the alkalies and earths, were formed by Scheele; but their properties are still almost completely unknown. The supermolybdat of potass alone has been described with some detail. It is formed by detonating one part of sulphuret of molybdenum and three parts of nitre in a crucible. By dissolving the reddish mass which remains after this operation, and filtering, a solution is obtained of potass and molybdat of potass is obtained. By evaporating the solution, the sulphat of potass is separated; when sulphuric acid is dropped into the remaining liquid, supersupraborau of potass is precipitated. This salt is soluble in water. Its solution crystallizes by evaporation in small rhomboidal plates inserted into each other. They are bright, and have a metallic taste. When exposed to the blowing air, and melted without swelling, and are converted into small globules, which are quickly absorbed by the charcoal. When melted with a mixture of phosphat of soda and of ammonia (or micromosic salt), they communicate a green tinge. Hot water dissolves them completely, and purifies of potass occasions in this solution a reddish brown precipitate. When a solution of nutria of tin is poured upon them, they acquire a blue color.

MOLYBDENUM. The Greek word ρυλοβδεν, and its Latin translation plumbago, seem to have been employed by the ancients to denote various oxides of lead; but by the moderns they were applied indiscriminately to all substances possessed of the following properties: Light, irridelescent, and soft, of a dark color and greasy feel, and which leave a stain upon the fingers. Scheele first examined these minerals with attention. He found that two very different substances had been confounded together. To one of these, which is composed of carbon and iron, he appropriated the word plumago; the other he called molybdio.

Molybdio composed of scaly particles adhering slightly to each other. Its color is bluish, very much resembling that of lead.

Scheele analysed it in 1778, and obtained sulphur and a whitish powder, which possessed the properties of an acid, and which, therefore, he called a kind of molybdina. Bergman suspected this acid, from its properties, to be a metallic oxide; and at his request, Scheele, in 1782, undertook the laborious course of experiments by which he succeeded in obtaining a metal from this acid. His method was to form it into a paste with melted oil, and then to apply a very strong heat. This process he repeated several times successively. To the metal which he thus obtained he gave the name of molybdum. The experiments of Scheele were afterwards repeated by Pelletier, Bismarck, and Meyer: and not only fully confirmed, but discovered many new facts, and the metallic nature of molybdic acid was put beyond a doubt: though, in consequence of the very violent heat necessary to fuse molybdum, only very minute grains of it have been hitherto obtained in the state of a metal.

MOYSDYUNUM. This oxide, having the properties of an acid, is known by the name of molybdic acid.

From the experiments of Mr. Hatchet, it follows that molybdium is capable of combining with four different proportions of oxygen, and of forming four oxides; namely, 1. The black; 2. The blue; 3. The green, to which Mr. Hatchet has given the name of molybdous acid; and 4. The yellow or white, the molydine. Molybdenum combines readily with sulphur and the compound has exactly the properties of molydina, the substance which Scheele decompoundled. Molybdenum is therefore sulphuret of molybdium. The reason why from molybdic acid was, that the metal was isolated with oxygen during his process. Sulphuret of molybdium may be formed also by dissolving...
MOMORDICA. Of these are very scarce, having been found only in India, Germany, Ceylon, among the Alps, near Tuscany, and in the island of Lewis, in Scotland. The only species known is mollybdema, which is found commonly massive; sometimes, however, it is crystallized in hexagonal tables. Colour light yellow; sometimes with a shade of red. Streak blue-grey, metallic. Powder blueish-black, flexible. Species hexaerial. Marks bluish-black. A piece of resin rubbed with this mineral becomes positively electric. Insoluble in sulphuric and muriatic acids. Composed of molybdolum. 60 molybdolum 40 sulphur.

100

MOMENT, in the doctrine of infinites, denotes the same with infinitesimal.

MOMENT, momentum, in mechanics, signifies the same with impetus, or the quantity of motion in a moving body; which is always equal to the quantity of matter, multiplied into its velocity; or, which is the same thing, it may be considered as a rectilinear angle under the quantity of matter and velocity.

MOMORDICA, male balsam apple; a genus of the syneogene order, in the monotypic family; and in the natural method ranking under the 34th order, cucurbitaceae. The male calyx is quiquefid; the corolla sexpartite; the filaments are three in number. The female calyx is trifid; the corolla quiquepartite; the stile tristis; the fruit is an apple, partially asperous with a spring. There are eight species, the most remarkable of which are, 1. The Balsamina, or male balsam apple. This is a native of Asia; and has a trailing stalk like those of the cucumber or melon, with smooth leaves, cut into several segments, and spread open like a hand. The fruit is oval, ending in acute points, having several deep angles, with sharp tubercles placed on their edges. Colour yellow or yellowish orange when ripe, opening with elasticity, and throwing out its seeds. 2. The calidus, wild or sporting cucumber, has a large fleshy root, somewhat like briony, whence come forth, every spring, several thin, rough, trailing stalks. The flowers come out from the wings of the stalks: these are male and female, growing at different places on the same plant like those of the common cucumbers; but are much less tall and of a dull yellow colour, with a yellowish bottom; the male flowers stand upon thick, short, foot stalks, but the female flowers sit upon the young fruit; which, after the flower is faded, grows into an oval form, an inch and a half long. Leaves, of a grey colour, like the leaves, and covered over with short prickles. This species has one of its names from the property of casting out its seeds, together with the sweet juice in which the seeds are bathed, with a violent force, if touched with a white tip. The first species is famous in Syria for curing wounds. The natives cut open the unripe fruit, and infuse it in sweet oil, which they expose to the sun for some days, until it becomes red, and then present it for use. Dropped on cotton, and applied to a fresh wound, the Syrians reckon this oil the best vulnerary next to balsam of Mecca, having found by experience that it often cures large wounds and ulcers. The leaves and seeds of this plant are used for abatours or bowers. The calidus of the shops is the fruit, or rather the inspisated fructis, of the juice of the unripe fruit of the wild cucumber. It is usually sent from Spain and the South parts of France, where the plant is common. We receive it in small, flat, whitish lumps, or cakes, that are dry, and break easily between the fingers. It is of an acrid, nauseous, bitter taste; and gives a strong offensive smell when newly made; but these, as well as its other properties, it loses, after being kept for some time. It is a very violent purge and vomit, and is now but seldom used.

MOMOTUS, a genus of birds of the order peris. The generic character is, bill strong, slightly curved, serrate at the edges; nostrils feathered; tongue feathered; tail wedge; feet formed for walking. There is but one species, the Brasilien, that inhabits Brazil; size of a black and eighteen inches long, lives solitary in unfrequented forests; building a nest of dry grass on the ground, or in holes abandoned by the armadillo, and lays two eggs; feeds on insects and raw flesh, the fragments of which it maccrates in water, which it drinks violently after its bill. Its voice is harsh, weak, tremulous.

MONADELPHIA, (from monos alone, and adelphos a brotherhood) is a "single brotherhood." The name of the 16th class in Linnaeus's sexual system, consisting of plants with hermaphroditic flowers; in which all the stamens, or male organs of generation, are united below into one body or cylinder, through which pass the pointal or female organ.

MONANDRIA, (from monos alone, and andros a man or husband;) The name of the first class in Linnaeus's sexual system; consisting of plants with hermaphroditic flowers, which have only one stamen or male organ.

MONARDA, Indian horbedow; a genus of the monogyonia order, in the diandria class of plants; and in the natural method ranking under the 41st order, verticillate. The corolla is unequal, with the upper lip flat, linear, toothed at the base; the flower is about half an inch in length. There are seven species; the most remarkable is the didyma, a native of North America. It is herbaceous. The flowers, which are of a bright red, surround the stalk in wheels, each wheel containing about 14 flowers; and are succeeded by four small kidney-shaped shining seeds, lodged in the bottom of the permanent flower-cup. The Indians superstition believe that a fragment of this plant is efficacious for driving away the devil.

MONAS, a genus of vernes, order infrusoria. The generic character is worm invisible to the naked eye, most simple, pelliculate, resembling a point. There are two species; the terminal, the most minute, simple gasteron: point is to be found in most animal and vegetable infusions: of all animals the most minute, being so extremely delicate and transparent, as to elude the most highly magnifying powers, blending in a manner with the water in which it swims.

MONETIA, a genus of the class and order tetrandria monogynia. The cal is four-lobed; petals four; berry two-seeded: seeds solitary, a species, a shrub of China and India.

MONEY. The era of the invention of money is not easy to be settled. There is no room to doubt, but that in the earliest ages the ordinary way of traffic among men was by trucking or exchanging one commodity for another; but in course of time it was found necessary, in the way of commutative justice, to have some common measure or standard, according to which all things should be estimated.

Money is usually divided into real and imaginary. Real money includes all coins, whether of gold, silver, copper, or the like; such as guineas, crowns, pistoles, pi ces of eight, ducats, &c. for an account of which we refer the reader to the article Coin. Imaginary money, or money of account, is that which never existed, or, at least, which does not exist in real specie; but is a denomination invented or retained to facilitate the stating of accounts, by keeping them still on a footing analogous to current coin.

No person is obliged to take in payment any money which is not lawful metal, that is, of silver and gold, except for sums under sixpence. 2 fl 577.

But it was decided in Hilary term, 1790, that bank notes were considered as money, and therefore a proper tender in payment.

English Money of account, is the pound, shilling, and pence; the pound contains twenty shillings, and the shilling twelve pence.

The old Scotch Money of account was the pound, shilling, and penny; the pound containing twenty shillings, being equivalent to one shilling and eightpence English; and the shilling containing twelve pence, equal to a penny English. There is also among them an account of marks, the mark being equivalent to one shilling 1½ penny English: this last kind they had formerly a silver coin.

French Money of account, is France, sous, cent, &c.
Dutch Money of account, is kept at Amsterdam and Rotterdam, the two chief trading places in guilders, schillings, and pence; so that though goods are sold for other species, such as livre de gros, &c., yet all are reduced to the above denominations for the entries into their books. The exchanges are made with us in some shilling to a pound sterling, though in most other places in deniers-de-gros.

Spanish Money of account, is at Cadiz kept in rials of p.t.e and its fractions; at Castile, in maravedis; at Vall-eac'h, in livres or dollars, suedois and ducors; of which last twelve make a suelde, and twenty sueldos a livre or dollar. Seventeen quartos, at Cadiz and Castle, make two rials vellon, which is now an imaginary coin, though formerly it was the principal one of the kingdom. A maravedis is another imaginary species, of which seventeen is reckoned to a real vellon. The ducor is also a fictitious coin of eleven rials of plate in purchases, sales, and other mercantile transactions, except in exchanges, in which they are reckoned at sixteen times the value of the real.

Portuguese Money of account, is kept in rrs, or reis, making a separation at every hundred, thousand, &c. 800 reis go to a moidore.

German and Swiss Money of account. At Coningberg, Elbing, and Danitz, accounts are kept in rixdollars and gros, or in Polish guilders, gros, and deniers, or pennies. They exchange on Amsterdam in Polish gros for a livre de gros of six guilders current money of Amsterdam, and on Hamburg for the rixdollar. At Luebec, accounts are kept in marks, schellings, and deniers or pennies, in which their exchanges are made. At Breslaw, accounts are kept in rixdollars and silver gros and pennies; in the first of which species exchanges are made on Amsterdam for a certain number of silvers, bank money, and on Hamburg for rixdollars of Breslaw against rixdollars of Hamburg bank. Hamburg accounts are kept in marks, schellings, and deniers or bank money, by those who have cash in the bank, but by those who have not, their books are generally kept in rixdollars, and marks only.

At Bremen, accounts are kept in rixdollars and gros, and it exchanges on Amsterdam rixdollars of seventy gros for rixdollars of fifty silvers banco. At Leipsie and Naunbourg, accounts are kept in rixdollars, crowns, gros, and pennies. At Berlin, and in all this kingdom, accounts are kept in guilders, gros, and pennies. At Zurich, accounts are kept in rixdollars, schillings, and hellers; reckoning the 9 dollars (worth about 4s. 6d. sterling) at 10s. of their cruziers. At Frankfort on the Main, and Hanau, accounts are kept in rixdollars and cruziers. At Vienna, accounts are kept in guilders, cruziers, and pennies, reckoning eight pence to a cruzier, and sixty cruziers to a guilder. At Nuremberg and Augsburg, accounts are kept in guilders, cruziers, and hellers; at Liége, in livres, sous, and deniers.

In the custom of St. Gall, in Switzerland, accounts are kept in guilders, cruziers, and pennies; or under the same denomination with the coins of the empire. In the canton of Basel, accounts are variously kept, some in rixdollars, schillings, and deniers; some in shillings, pounds, and pence, and in schellings, escudi, and pesetas; and some in cruziers, guilders, and pennies; and in guilders, cruziers, and pennies.

Italian Money of account. At the cities of Genoa and Novi, accounts are kept in livres, soldi, and denari; or in dollars of 100 soldi. At Milan, accounts are kept in livres, deniers, and sols, equal counted like pounds, shillings, and pence, viz. twenty denari to a soldo, &c. At Rome, accounts are kept in crowns, juliets, and bajocches, or grains and quarts; the crown is divided into ten juliet, and the juliet into ten bajocches. At Leghorn, accounts are generally kept in dollars, soldi, and denari. At Florence, they keep their books and accounts in crowns, soldi, and denari, picciol or current money. At Naples, accounts are kept in dukats, florins, and grains. The accounts in Sicily are kept the same as at Naples. At Lucca they keep their accounts in crowns, livres, soldi, and denari; the crown is worth 7 livres 10 soldi; the livre, 20 soldi; and the soldo, 12 denari. At Bologna, accounts are kept in livres, soldi, and denari, picciol or current money; but the bank-entries are in livres, soldi, and gros; both the current and bank-ducat of Venice make 24 soli, or six livres and 4 picciolo. At Bologna, accounts are kept in livres, soldi, and denari; the livre being 20 soldi, and the soldo 12 denari. At Bergum, the money of account is the same as at Bologna, and its proportions the same. In Urbino, accounts are kept in crowns, soldi, and denari; the crown is 20 soldi, and the soldo 20 denari. At Modena and Mantua, accounts are kept in livres, soldi, and denari. In Savoy and Piedmont, accounts are kept in livres or livres, soldi, and quarts. In Flanders, accounts are kept in crowns, soldi, and denari of mark; of which 12 denari make a soldo, and 20 soldi the crown. In the island of Sardinia, accounts are kept as in most parts of Italy, in livres, soldi, and denari. In the island of Malta, the money of account is the same with that of Sicily. In the island of Candia, the account is the same as at Venice.

Russian, Swedish, Danish, and Polish Money of account. In the tracing places, the king of the Low Empire keeps accounts in rixdollars, crowns, gros, and pennies; and the English money is kept in rixdollars and gros and it exchanges on Amsterdam rixdollars of seventy gros for rixdollars of fifty silvers banco. At Leipsie and Naunbourg, accounts are kept in rixdollars, crowns, gros, and pennies. At Berlin, and in all this kingdom, accounts are kept in guilders, gros, and pennies. At Zurich, accounts are kept in rixdollars, cruziers, and hellers; reckoning the 9 dollars (worth about 4s. 6d. sterling) at 10s. of their cruziers. At Frankfort on the Main, and Hanau, accounts are kept in rixdollars and cruziers. At Vienna, accounts are kept in guilders, cruziers, and pennies, reckoning eight pence to a cruzier, and sixty cruziers to a guilder. At Nuremberg and Augsburg, accounts are kept in guilders, cruziers, and hellers; at Liége, in livres, sous, and deniers.

In the custom of St. Gall, in Switzerland, accounts are kept in guilders, cruziers, and pennies; or under the same denomination with the coins of the empire. In the canton of Basel, accounts are variously kept, some in rixdollars, schillings, and deniers; some in shillings, pounds, and pence, and in schellings, escudi, and pesetas; and some in cruziers, guilders, and pennies; and in guilders, cruziers, and pennies.

Moneys of account of other islands and countries of India. Throughout Malabar, and at Gou, they use tansas, vintins, and pattir-xepin; the tanga is of two kinds, viz. of good and bad alloy; hence their custom is to count by good or bad money; the tanga of good alloy is better by one-fifth than the bad, so that 4 tanguas being equal to the good dollar, there will be required 5 of the bad; 4 vintins good make a tanga likewise good; 15 barusas, a vintin; a good baruco is equal to a Portuguese ree, a French ducat, or one-thirteenth of a penny sterling.

The small coin of the island of Java they use the santapac, lardos, and catas; which last money, together with the lados, is used throughout all the East Indies; the lota is 200 caxas, or little pieces of that country, hung on a string, and is equal to eleven-twelfths of a penny sterling; five santas make the supa on. The tanga is equal to 2s. 6d. sterling; the catas to 20 tals; the lados to 8s. sterling. There are islands, cities, and states, of the East Indies, whose monies of account are not here expressed, partly because reducible to some of the
MONKEY. See Simia.

MONOCHORD, a musical instrument, composed of one string, used to try the variety and proportion of sounds.

It is formed of a rule, divided and subdivided into several parts, on which there is a moveable string stretched upon two bridges at each extreme. In the middle between these is a moveable bridge, by means of which, in applying it to the different divisions of the scale, the sounds are found to bear the same proportion to each other as the division of the line, cut by the bridge. There are also monochords with forty-eight fixed bridges. The following is the account of a monochord given by Earl Scudamore:

1. The wire is not made either of brass or iron, but of steel, which is very far superior. For, steel wire does not keep continually lengthening, as brass and iron wires do when they are stretched considerably.

2. The monochord does not, as usual, pull downwards on the bridges, but the whole wire forms one straight and horizontal line, by which means the moveable bridge, which determines the exact length of the wire, can be moved without altering the tension of the wire. This is not the case when the wire pulls downwards on the bridges.

3. The ends of the wire are not twisted round the two stout steel pins which keep it stretched; but each end of the wire is soft-soldered in a long groove formed in a pair of steel chisel-shaped corresponding pins. This is a great improvement.

4. One of those two steel pins is strongly fastened on a brass slider, which is moved by means of a screw with very fine threads, which screw has a large micrometric head minutely divided on its edge, and a corresponding notch; so that the tension of the wire may be adjusted with the greatest precision, in order to obtain its exact pitch.

5. A slider is fixed across the top of the moveable bridge, and is moved by means of another screw with very fine threads; so that the length of the wire may be regulated with the greatest nicety in all cases.

The above-mentioned slider, which is on the top of the moveable bridge, is adjusted to the steel rod or scale, not by sight, or by the coincidence of lines, but by means of mechanical contact against projecting pieces of steel firmly fixed on the bridge, which in the present instrument is incomparably more correct.

Each bridge carries a metallic finger, which keeps the wire close to the top of the bridge, whilst the wire is made to vibrate. The vibrations of the wire are produced by touching it with a piece of cork, with the same elastic force, and on the very same spot each time, namely, at the distance of one inch from the immovable bridge.

MONNIESIA, a genus of the class and order Delphina, the calf is five-parted; corolla stellata; stamens 3, capsules 5, 1-seeded. There is one species, an American annual.

MONOCULOS. Monoculus, a genus of the order Aperta; the generic character is, feet formed for swimming; body covered by cuticular segments; eyes, in most species, approximated, and imbedded in the shell.

Of the monoclous, by far the largest are very small water-insects, requiring the assistance of a microscope for the investigation of their particular organs; some however are so large as to require the use of an ordinary glass. There is one species in particular, (if, indeed, it can be allowed to stand with propriety in the genus) is of a size so gigantic, that it is generally considered as the largest of the crustaceous tribe.

This animal is the monocus polyphemus of Linnaus, commonly distinguished by the title molucca or king-crab. Specimens are sometimes seen of two feet in length, exclusive of the shell. It is a native of the Indian ocean, and is said to be generally found in pairs, or male and female swimming together. The colour of the whole animal is a yellowish-brown; the shell is very convex, rounded in front, and lunate behind, where it joins the lower part of the body; this, which is of the same crustaceous nature, is marked on each side by several spiny incisions; the legs, which are seven on each side, are situated beneath the concavity of the large or rounded part of the shell; and are each terminated by a double claw, those of the lowest pair having some additional processes: the branched, or respiratory, organs are disposed in the form of several flat, rounded, imbricated lamelle on each side the lower part of the body; the tail, which is stratified, triangular, and of the same crustaceous nature with the rest of the shell, is equal in length to the whole body, and gradually tapers to a sharp point. The eyes in this species, instead of being approximated, and of the same character, are extremely distant from each other, being situated towards the sides of the shell; they are of a semicircular form, and the surface is divided into a great number of minute conical convexities; this part however should be considered as only constituting the concave or exterior covering of each eye; the organs themselves being, according to the observations of Mr. Petiver, in the Philosophical Transactions, placed on a pedicle beneath each of the above-mentioned semicircular cornea. Petiver's words are these. "The whole structure of this animal is very remarkable, and particularly his eyes, viz. between the fourth and last pair of claws on each side, reckoning from his mouth, and excluding the small pair thereof, there are, are inserted the rudiments of another pair, or a claw broken off on each side at the second joint or elbow; on these are six eyes, like those of the hands of snails, but under the skin, they are thick and opaque shell. Nature in that place has wonderfully contrived a transparent lantern, through which the light is conveyed, whose superficies very exactly resembles the great eyes of one of the larger limpets or abalone, which have the naked eye phanically perceived to be composed of an immeasurable globule: these, like them, are oblong, and guarded by a testaceous superciliar clique."

Of the European monoclous, by far the largest is the monocus apus, which, when full-grown, measures nearly an inch and three quarters from the front to the end of the body, exclusive of the forked divisions of the tail. It is found in muddy stagnant waters, but is a rare species in this country, having been only observed in a few particular situations. In its general shape, it is considerably allied to the large exotic species before described, but the animal is not of more length in proportion, with the hinder part naked, and divided into numerous joints: the branchiæ, or respiratory organs, are large, and are distributed into numerous imbricated rows on the under side of the body. There is a pair of joined, thin arms, extending on each side to a considerable distance; the eyes are placed near each other in front of the shell; the tail is terminated by a pair of long forks or ctenes, processes. The colour of the whole is a pale greenish-brown above, and reddish beneath. We are informed in vol. 40 of the Philosophical Transactions that this insect has been found in great plenty in a pond on Twickenham Common, in Kent. It is also added, that the same pond, having been perfectly dried, and being suddenly filled during a heavy thunder-storm, swarms of the same animal were again observed in it within the space of two days after.
the tenth of an inch, but it is sometimes seen considerably larger: its shape is oval, somewhat truncated in front, and sharply pointed behind: the body is inclosed in a bivalve, transparent by the microscope, appears finely reticulated: on each side the head is a strong transparent jointed arm, reaching into two divisions, and terminating in several venous branches: the tail, which is generally inclosed within the shell, is occasionally protruded in the form of a strong curved and pointed process; the eyes of this animal are of a singular construction; they are large in proportion to the insect, placed very near each other, appear to consist of many separate globules, of a black colour united under a common skin.

MONODON MONOCRÆOS, UNICORN NARWHAL, is a native of the northern seas, where it is sometimes seen of the length of more than twenty feet from the mouth to the tail; and is at once distinguishable from every other kind of whale by its very long, ivory-like tooth, which is perfectly straight, of a white or yellowish-white colour, and wreathed throughout its whole length, and gradually tapering to a sharp point. It measures from six to nine or ten feet in length, and proceeds from a socket on the one side of the upper jaw, and in each eye at the base or root, running through the greater part of the whole length. In the young animals and occasionally even in the full grown ones, more especially in the males, there are two of these teeth, sometimes but very small, and sometimes very unequal in this respect: they are seated very close to each other at the base, and as their direction is nearly in a straight line, they diverge but little in their progress towards the extremities. The head of the narwhal is short, and convex above: the mouth small; the spiral or breathing-hole doubled within; the tongue long; the pectoral fins small; the back, finless, wide, convex, becoming gradually acuminiated towards the tail, which, as in other whales, is horizontal. The general form of the animal is rather long than thick in proportion to its size. The colour, when young, is said to be nearly black, but lightens as the animal advances in age, it becomes marbled or variegated with black and white on the back and sides, while the belly is nearly white. The skin is smooth, and there is a considerable depth of oil on the under side. The narwhal chiefly inhabits the northern parts of Davis's Straights. Its food is said to consist of the smaller kind of flat-fish, as well as of actinids, medusæ, and many other marine animals. It is principally seen in the small open or unfrozen spots towards the coasts of the northern seas. To such places it resorts in multitudes, for the convenience of breathing, while at the same time it is sure of finding near the shores a due supply of food, and is very rarely seen in the open sea. It is taken by means of harpoons, and its flesh is eaten by the Greenlanders, both raw, boiled, and dried: the intestines and oil are also used as a food; the tendons make a good thread, and the teeth serve the purpose of hunting-horns as well as the more important ones of building tents and houses: but before this animal became distinctly known to the naturalists on account of their being in high estimation as the supposed horns of unicorns. Various medical virtues were also attributed to them, and they were even numbered among the articles of magnificence. A throne made for the Danish monarchs is said to be still preserved in the castle of Rosenberg, which is composed of narwhal's teeth; the ivory material being antiently considered as more valuable than gold.

A specimen of this whale, measuring about sixteen feet, exclusive of the horn or tooth, and at some time stranded on the coast of Labrador, at a great distance from Boston, and was said to have been taken alive.

2. Monodon spurious, spurious narwhal. A species most allied to the narwhal, but not perhaps, strictly speaking, of the same genus: no teeth in the mouth, but from the extremity of the upper mandible project two minute, conic, obtuse teeth, alike, curved at the tips, weak, and not above an inch long: body elongated, cylindrical, black. Besides the pectoral fins, and horizontal tail, is also a minute dorsal fin. It must be numbered among the rarities of the whales. Its flesh and oil are considered as very purgative: inhabits the main ocean, seldom coming towards shore: feeds on the polipo: has a spiral like other cetacea. There is no doubt of both these animals, but not without apprehension, for the reason already mentioned.

MONODON narwhal, a genus of mammalia of the order ceteæ; the generic character is, teeth two in the upper jaws, extending straight forward, long, spiral: a plate on the fore and upper part of the head. It inhabits the Atlantic, swims rapidly, and is from 18 to 40 feet long and 12 broad. Skin white, spotted on the back with black; dorsal fins: pectoral, two small: head small: eyes very minute: what are commonly exhibited as the unicorns horns. See Plate Nat Hist. fig. 269.

MONOCÉRIA, from monos alone, and ceras, a horn; the name of the 21st class of Linæus's sexual method. See BOTANY.

MONOGYNIA, from monos alone, and gynos, a woman; the name of the first order or subdivision in the 13 classes of Linæus's sexual method; consisting of plants, which, besides their agreement in their classic character, generally derived from the number of the stamens, have only one style: or female organ. See Botany.

MONOGRAM, a character or cypher, composed of one, two, or more letters interwoven: being a kind of abbreviation of a name, antiently used as a seal, balze, arms, &c.

MONOPOLY, is an allowance by the king, by his grant, commission, or otherwise, to any person or persons, bodies politic or corporate; or of, or for, the sole buying, selling, making, working, or using of any thing, whereby any person or persons, bodies politic or corporate, are sought to be restrained of any freedom or liberty they had before, or hindered in their lawful trade. 3 Inst. 181.

But it seems that the king's charter, imposing particular persons to trade to and from such place is void, so far as it gives such persons an exclusive right of trading, and debarring all others; and it seems now agreed, that nothing can exclude a subject from trade but out of his own consent. Plut. 480.

MONOPOLY, is a genus of the fishes of the order aepodicæ; the generic character is, body anguilliform: nostrils placed between the eyes: fin caudal.

1. The Monopterus Javanicus, the only animal of this genus hitherto discovered, is, thus described by the Count de la Cama, from the manuscripts of Comerson, by whom it was considered as a species of Micrurus. The body is serpentiniform, viscosus, and destitute of conspicuous scales; the head thick, compressed, angling towards the back part, and terminated in front by a rounded muzzle: the gape is rather wide; the upper jaw scarcely projecting beyond the lower; both being furnished with close teeth; the gill membrane has only three rays, and the branchial are only three in number on each side; the lateral line, which is nearer the belly than the gills, extends from the gills to the extremity of the tail, and is almost of a golden colour; the skin is of a livid brown or blackish colour. This fish is a native of the Indian seas and is very common about the coasts of Java, where it is considered an excellent food.

MONOSIA, a genus of the dodecaandria order, in the polypetalous class of plants. The calyx is pentamericulous; the corolla pentapetalous and irregular; the stamina are 15 in number; and coiled into five filaments; the style bifid; the capsule pentagonous. There is one species.

MONSOON. See WIND.

MONTH, the twelfth part of a year. See CHRONOLOGY.

MONTIA, water chickweed, a genus of the order, in the triquetra class of plants; and in the natural method ranking with those two of which the order is doubtful. The calyx is diphylous; the corolla monopetalous and irregular; the capsule unicellular and invexed. There is one species.

Mood, or Mode, in grammar, the different manner of conjugating verbs, serving to denote the different affections of the mind. See MOOD.

MOONSTONE. This is the purest felspar hitherto found. It occurs in Ceylon and Switzerland; and was first mentioned by Mr. Poni. Specific gravity, 2.599. Colour white; sometimes with a shade of yellow, green, or red; it is surface sometimes streaked. A specimen of it analysed by Vaucquelin, yielded,

MOORING, in the sea-language, is the laying out the anchors of a ship in a place where she can ride secure. Moorings are used, to lay out on each side; and mowing along, is to have an anchor in a river and a hawser on shore. When ships are laid up in ordinary, or are under orders of fitting for sea, the mooms are laid out in bays; and consist of claves, pendant chains, cables, bridles, anchors, swivels, jers-lars, buoys, and chains.
MORDELLA, a genus of insects of the order coleoptera. The antennae are thread-shaped and serrated; the head is deflected under the neck: the pappi are elevated, compressed, and obliquely blunted; and the elytra have a few hairs near the apex. There are six species.

MORFA, a genus of the monogynia order, in the triandria class of plants; and in the natural method ranking under the 45th order, aggregatea. The corolla is hexagonal; the three interior petals, patent; the rest like those of the iris. There are 17 species, beautiful exotics, resembling the iris.

MORRAS, a genus of the monogynia order, in the triandria class of plants; and in the natural method ranking under the 45th order, aggregatea. The corolla is unequal; the calyx of the fruit is monoplylous and dehiscent; the calyx of the flower bud; there is not seed under the calyx of the flower. There is one species.

MORNA, a genus of the monogynia order, in the pentandria class of plants; and in the natural method ranking under the 45th order, aggregatea. The corolla is tetratape lateral; the one pistil; the berry has a hard bark, laminolar, polygonal, smooth, unmarked, uncolored. There is one species, a tree of South America.

MORNYRUS, a genus of fishes of the branchiostegous order, the generic character is, head smooth; teeth numerous, notched; aperture of the gills linear, without a cover; gill membrane with one ray; body small. There are three species. The kumu of the tail, obtuse; dorsal fin with 63 rays. It inhabits the Nile; body whitish and much compressed.

MORROCO, maroquin, in commerce, a fine kind of leather prepared from the skin of an animal of the goat kind, and imported from the Levant, Barbary, &c.

The pelts only taken from the kingdom of Morocco, whence the manner of preparing it was borrowed, which is thus: the skins being first dried in the hair, are steeped in water three days and nights; then stretched on a tanner's horse, beaten with a large knife, and steeped afresh in water every day: they are then tawed into a large vat in the ground, full of water, where quinoline has been skaked, and there lie fifteen days; whence they are taken, and again returned every night and morning. They are next thrown into a fresh vat of lime and water, and shifted night and morning for fifteen days longer; then rinsed in clear water, and the hair taken off the leg with the knife, returned into a third vat, and shifted as before for eighteen days; steeped twelve hours in a river, taken out, rinsed, put in pans, where they are pounded with wooden pe-ties, changing the water twice; then laid on the horse, and the flesh taken off; retained in water, tawed, and dipped in the hair-side-scarped; returned into fresh pans, taken out, and thrown into a pail of a particular form, having holes at bottom: here they are beaten for the space of an hour, and fresh water poured on from time to time; then being stretched on the leg, and scraped on either side, they are returned into pans of fresh water, taken out, stretched and sewed up all around in manner of bags, leaving out the hinder legs as an aperture for the conveyance of the water; and then hung. The skin thus sewed are put in lukewarm water, where dogs excrements have been disposed. Here they are stirred with long poles for half an hour, last at rest a dozen, taken out, rinsed in fresh water; and filled the same way with a preparation of water and suinate, mixed and heated over the fire till ready to boil; and, as they are filled, the leg-kinds are sewed up to stop the passage. In this state they are let down into the vessel of water and suinate, and kept stirring for four hours successively; taken out and hanged on one another; after a little time their sides are changed, and thus they continue an hour and a half tied drained. This done, they are boiled, and filled a second time with the same preparation, sewed up again, and kept stirring two hours, piled up and drained as before. This process is again repeated, with this difference, that the skins are left in the water one hour; after which they are let till next morning, when they are taken out, drained on a rack, unvished, the suinate taken out, folded in two iron head to tail, the hair-side outward; laid over each other on the breast, to perfect their draining, stretched out and dried; then trampled under foot by two and two, stretched on a wooden table, what flesh and suinate remain scraped off, the hair-side rubbed over with a handful of rushes, to squeeze out as much of the oil remaining as possible. The first course of back is now laid on the hair-side, by means of a lock of hair twisted and steeped in a kind of black dye, prepared of sour beer, wherein pieces of old rusty iron have been thrown. When half-lined in the air, they are stretched on a table, rubbed over every way with a panelle, or wooden-toothed instrument, to raise the hair, and that part of the skin which is on the couch of water, then seckled by rubbing them with rushes prepared for the purpose. Thus seckled, they have a second course of black, then dried, laid on the table, rubbed over with a panelle of cocoa, to raise the grain again; and, after a light couche of water, seckled over anew; and to raise the grain a third time, a panelle of wood is used. After the hair-side has received all its preparations, the skin is pared with a sharp knife for the purpose: the hair-side is strongly rubbed over with a wooden cap, having before given it a gloss with barberries, citron, or orange. The whole is finished by raising the grain lightly, for the last time, with the panelle of cocoa; so that they are now fit for the market.

Manor of preparing red Morocco: after steeping, stretching, scraping, beating, and raising the skins, as before, they are at length prepared; and that they are ready for market, after each other into water where alum has been dissolved. Thus alanned, they are left to drain till morning, then wrung out, pulled on the leg, and folded from head to tail, the flesh forwards.

In this state they receive their first dye, by passing them over another into a red liquor prepared with laque, and some other ingredients, which the maroquiniers keep a secret, and they never agin, then the skins have got their first colour: then they are raised in clear water, stretched on the leg, and left to drain twelve hours, thrown into water through a sieve, and stirred incessantly, for a day with long poles taken out, hung across the water all night, white against red, and red against white, and in the morning the water stirred up, and the skins returned into it for twenty-four hours.

MORTALITY, Bible, s., accounts of the numbers of deaths or burials in any parish or district. The establishment of registers of this kind in Great Britain, was occasioned by the plague, and an abstract of them was published weekly, to show the increase or decrease of the disorder, that individuals might judge of the necessity of removal, or of taking other precautions against it, and government be informed of the propriety or success on any public measures relating to the disorder. On 21st Dec., 1594, and on the 21st of the same month, who also appointed a proclamation to be made by the clergy, in which, among other things, they promise to keep the register-book in a proper manner. One of the canons of the church of London, in which manner entries are to be made in the parish-registers, and orders an attested copy of the register of each successive year to be annually transmitted to the bishop of the diocese or bishoprick, and to be preserved in the bishop's registry. These registers have only been occasionally communicated to the public, and that without sufficient particulars to supply much information; but in London, and the surrounding parishes, the parish-clerks are required to make a weekly return of burials, with the age and disease of which the person died; a summary of which account is published weekly; and on the Thursday following the last day of the week, who also appoint the register is made up for the whole year. These accounts of christenings and burials, taken by the company of parish clerks of London, were began 21st Dec., 1592, but were not made public till 1604; and to this day, in the following year, upon the ceasing of the plague, they were discontinued; at this time the London bills of mortality comprehended but 109 parishes. In 1603, the weekly bills of mortality were reduced, and have been regularly continued ever since; the number of parishes included in them has been increased at different times, and at present is 148.

Bills of mortality, especially such as give the ages of the dead and the disorders of which they died, furnish much useful information; they shew the different degrees of healthness of seasons or districts, the progress of population, and the probabilities of the duration of human life in any part of the usual habitations; and the observations on which all tables of the value of annuities on lives, or depending on survivorship, have been constructed.

In 1693, Mr. John Granatt published some ingenious observations on the London Bills
of Mortality, which were much enlarged in subsequent editions. Dr. William Hooper, in 1653, made considerable use of the information afforded by them, in his Political Arithmetic. In 1742, Mr. T. Simpson published his Treatise on Annuities, in which he inserted a table formed of ages and years, derived from the London bills of mortality, with some corrections which appeared necessary: in 1746, Mr. De Parteux, in an Essai sur les Probabilités de la Vie humaine, made some objections to Mr. Simpson’s deductions in the London bills, but without sufficient foundation; and in 1757, Mr. Simpson, in a supplement to his Treatise on Annuities, made use of the same table from the London bills, but adapted to a different radix. In 1789, Dr. Price remarks, that in every place which just supports itself in the number of its inhabitants, without any recruits from other places, for a whole period of all ages, there has been no increase or decrease, the number of persons dying every year at any particular age, and above it, must be equal to the number of the living at that age. The number of females dying every year, at all ages, from the beginning to the utmost extremity of life, must, in such situation, be just equal to the whole number born every year. And for the same reason, the number dying every year at any particular age and upwards, at two years of age and upwards, at three and upwards, and so on, must be equal to the numbers that attain to those ages every year, or, which is the same, to the numbers of the living at those ages. It is obvious, that unless this happens, the number of inhabitants cannot remain the same; it follows, therefore, that in a town or country, where there is no increase or decrease, bills of mortality as at which place will shew the exact number of inhabitants; and also the exact law, according to which human life was in that town or country. In order to find the number of inhabitants, the number dying every year at any particular age and upwards, must be taken as given by the bills, and placed under one another in the order of the second column: see Table, art. expectation. These numbers will be the numbers of the living at 1, 2, 3, &c. years of age; and, consequently, the sum, diminished by half the number born annually, will be the whole number of inhabitants.

The bills of mortality, in some parts of Great Britain, are known to be materially defective; the deficiencies may chiefly be ascribed to the following circumstances: 1. Many congregations of dissenters, inhabiting towns, have their own peculiar burying-grounds, as have the Jews, and the Roman Catholics, who reside in London. 2. Some persons, from motives of poverty or convenience, inter their dead without any religious ceremony; this is known to happen in the most populous towns of France, and in a few other large towns. 3. Children who die before baptism are interred without any religious ceremony, and consequently are not registered.

Although after breach of the condition, an absolute fee-simple is vested at common law in the mortgagee; yet a right of redemption being still inherent in the land, till the equity of redemption is foreclosed, the same right shall descend to, and be invested in, such successors, or assigns of the original person, if any, as shall have been no mortgage or incumbrance whatsoever; and as an equitable performance as effectually defeats the interests of the mortgagee, as the legal performance does at common law, the case is still hanging over the estate until the equity is totally foreclosed; on this foundation it is held that a person who comes in under a voluntary conveyance, may redeem a mortgage; and though such right of redemption is inherent in the land, yet the party claiming the benefit of it, must not only set up such right, but also shew that he is the person entitled to it. Hard. 495.

But if a mortgage is forfeited, and thereby the estate absolutely vested in the mortgagee at common law, yet a court or equity will consider the real value of the tenements, compared with the sum borrowed. And if the estate is of greater value than the sum lent thereon, they will allow the mortgagee many reasonable time to recall or redeem the estate, paying to the mortgagee his principal, interest, and costs. This reasonable advantage, allowed to the mortgagee, is called the equity of redemption. 2 Bl. Com. 123.

It is a rule established in equity, analogous to the statute of limitation, that after twenty years possession of the mortgagor, he shall not be disturbed, unless there are extraordinary circumstances; as when the mortgagor is covert, infants, and the like. 3 Atk. 313.

MORTISE, or Mortise, in carpentry, &c. a kind of joint, wherein a hole of a certain depth is made in a piece of timber, which is to receive another piece called a tenon.

MORTMAIN, signifies an alienation of lands and tenements, to any guild, corporation, or fraternity, and their successors, as bishops, parsons, vicars, &c. which may not be done without licence, and the lord of the manor; or of the king alone, if it is immediately held of him.

But in order to prevent any imposition in respect to the disposal of lands to charitable use, which might arise from a testator’s last will, and testament, construed from circumstances, from the money, goods other personal estate whatsoever, to be laid out or disposed of in the purchase of any lands, tenements, or hereditaments, shall be given, limited, or appointed by will, to any person or persons, bodies politic or corporate, or otherwise for any estate or interest whatsoever; or any ways charged or incurred by any person or persons whatsoever, in trust, or for the benefit of any charitable use whatsoever; but such gift shall be by deed indentured, witnessed by the presence of two or more credible witnesses, twelve calendar months at least before the death of such donor, and be enrolled in the high court of chancery within six calendar months.
thoughtful purposes. The wood of the mulberry-tree is yellow, tolerably hard, and may be applied to various uses in turning and carving; but in order to separate the bark, which is rough, thick, thickened, and fit for being made into ropes, it is proper to steep the wood in water.

Mulberry-trees are noted for their leaves affecting the principal food of the silkworm. The leaves of the alba, or white species, are preferred for this purpose in Europe; but in China, where the best silk is made, the works are said to be fed with those of the nigra variety. However, the valuations of white mulberry-trees are not confined to the nourishment of worms: they may be cut every three or four years like sauls and popular trees, to make faggots; and the sheep eat their leaves in winter, before they are burnt. This kind of food, of which they are extremely fond, is very nourishing; it gives a delicacy to the flesh, and a fineness and beauty to the wool.

The papyrifera, or paper-mulberry, is so called from the paper chiefly used by the Japanese being made of the bark of its branches. The leaves of this species also serve for food and the silkworm, and it is now cultivated with success in some of the most fertile districts of Japan. The white mulberry, which grows faster than the common mulberry, and at the same time is not injured by the cold, M. de la Bouvriere affirms that he procured a beautiful vegetable silk from the bark of the young branches of this species of mulberry, which he cut while the tree was in sap, and afterwards beat and steeped. The women of Louisiana procure the same kind of production from the shoots which issue from the stock of the mulberry at the beginning of the season, and which are four or five feet high. After taking off the bark, they dry it in the sun, and then beat it that the external part may fall off; and the internal part, which is fine bark, remains entire. This is again beaten, to make it still finer: after which they bleach it with dew. It is then spun, and various fabrics are made from it, such as nets and fringes; they even sometimes weave it, and make it into cloth. The finest sort of cloth is made of the branches of Otahite and others of the South Sea islands, is made of the bark of this tree.

The tinctoria is a fine timber-tree, and a principal ingredient in most of our yellow dyes, for which it is chiefly exported into Europe. The berries are sweet and wholesome; but not much used, except by the winged tribe, by whose care it is chiefly planted.

MOSAIQ, or mosaic-work, an assemblage of little pieces of glass, marble, precious stones, &c. of various colours, cut square and cemented on a ground of stucco, in such a manner as to imitate the colours of painting.

MOSCHUS, musk, a genus of quadrupeds of the order Carnivora: the generic character, bears none; from teeth in the lower jaw eight; tusks solitary, in the upper jaw scs.

1. Moschus moschiferus, Tibetan musk. The musk is one of those quadrupeds whose true form and natural history appear to have continued in great obscurity long after the introduction and general use of the celebrated perfume which it produces. To the antients it was unknown, and was first mentioned by the Arabians when used in their practice. The animal was by some considered as a kind of goat, by others as a species of deer or antelope, and was of course supposed to be a horned animal; nor was it till about the thirteenth century that a tolerably accurate description of the figure was to be found.

The size and general appearance of this animal resemble those of a small roebuck. It measures about three feet three inches in height, about two feet three inches in length, and four feet six inches from the top of the shoulder to the bottom of the foreshoof, and two feet nine inches from the top of the hock to the bottom of the hind foot. The upper jaw is considerably longer than the lower, and is furnished on each side with about two inches long. These tusks are of a different form from those of any other quadruped; being sharp-edged on their inner or lower side, so as to resemble, in some degree, a pair of small crooked knives: their substance is a kind of ivory, as in the tusks of the babirusa and some other animals.

The general colour of the whole body is a kind of deep iron-grey; the tips of the hairs being of a ferruginous cast, the remainder blackish, growing much paler or whitish towards the roots. See Plate Nat. Hist. fig. 279.

The female is smaller than the male, and wants the tusks: it has also two small testes.

The male supplies their well-known perfume: which is contained in oval receptacles about the size of a small egg, hanging from the middle of the abdomen, and peculiar to the animal. This receptacle is found constantly filled with a thick, pungent, brownish substance, the most powerful and penetrating smell; and which is no other than the perfume in its natural state. As soon as the animal is killed, the hunters cut off the receptacle or musk-bag, and tie it up ready for sale. The animals must of necessity be extremely numerous in some parts, since we are assured by Tavernier, the celebrated merchant and traveller, that he purchased, in one of his Eastern journeys, no less than seven thousand six hundred and seventy-three musk-bags.

So violent is the smell of musk, when freshly taken from the animal, or from quantities put up by the merchants for sale, that it has been known to force the blood from the nose, eyes, and ears, of those who have immoderately inhaled its vapours.

As musk is an expensive drug, it is frequently adulterated with various substances; and we are frequently at a loss to detect the admixture, which is often found in some of the receptacles, inserted in order to increase the weight. The smell of musk is so remarkably diffusive, that every thing in its neighbourhood becomes strongly infected with it; even a silver cup that has held musk in it does not part with the scent, though other odours are in general very readily discharged from metallic substances.

As a medicine it is held in high estimation in the Eastern countries, and has now been introduced into pretty general use among ourselves, especially in those disorders which are commonly termed nervous; and in convulsive and other cases, it is often exhibited in pretty large doses with great success.

2. Moschus moschiferus, or Indian musk, this species is said to be rather larger than the common or Tibetan musk, of the colour mentioned in the specific character, with the head character, skin, and eyes of a horse, upright oblong ears, and slender legs. See Plate Nat. Hist. fig. 280.

3. Moschus pygmaeus, or the pygmy musk, is considerably smaller than a domestic cat,
measuring little more than nine inches from the nose to the tail. Its colours is bright bay, white beneath and on the insides of the thighs. Its shape is beautiful, and the legs are so slender as not to be visible from the front; the head is rather large, and the aspect mild. It is a native of many parts of the East Indies and the Indian islands, and is said to be most common in Java, where the natives catch great numbers in seines, and sell the young to the market-men for sale. According to Mr. Pennant they may be purchased at so low a rate as two pence halfpenny a piece. There are three other species.

**MOSQUE.** A temple or place of religious worship among the Mahometans.

All mosques are square buildings, generally built with stone; before the chief gate there is a square court, paved with white marble, and low galleries round it, whose roof is supported by marble pillars. In these galleries the Turks wash themselves before they go to prayer, and on each side of the court there are a great number of lamps; and between these hang many crystal rings, ostrich's eggs, and other curiosities, which, when the lamps are lighted, make a fine show. As it is the custom of the Moslem to wear shoes or stockings on, the pavements are covered with pieces of stuff sewed together, each being wide enough to hold a row of men kneeling, sitting, or prostrate. The women are not allowed to enter, but stay in the porches without. About every mosque there are six high towers, called minarets, each of which has three little open galleries, one above another: these towers, in each of which mosques are, cover the head, and adorned with gliding and other ornaments; and from thence, instead of a bell, the people are called to prayer by certain officers appointed for that purpose. Most of the mosques have a kind of hospital belonging to them, in which travellers, of whatever religion soever, are entertained during three days. Each mosque has also a place called turbe, which is the burying-place of its founder, who is often a rich man, of long feet, long covered with green velvet or satin, at the ends of which are two tapers, and round it several seats for those who read the koran, and pray for the souls of the deceased.

**MOSS.** See **Muscus.**

**MOTACILLA.** The wagtail and swarb, a genus of birds of the order of passerines, distinguished by a straight weak bill of a subulated figure; a tongue lacertated at the end, and very slender legs.

1. The alba, or white wagtail, frequents the sides of ponds and small streams, and feeds on insects and worms. The head is black; in some the chin is white, and the throat marked with a black crescent. The breast and belly are white. The tail is very long, and always in motion. Mr. Willughby observed, that this species shifts its quarters in the winter, moving from the north to the south of England during that season. A thing and amongst it is a constant attendant on the plough, for the sake of the worms thrown up by that instrument.

2. The flava, or yellow wagtail, migrates in the north of England, but in Hampshire continues the whole year. The male is a third of great beauty; the breast, belly, thighs, and vent-feathers, being of a most vivid and lovely yellow. The colours of the female are far more obscure than those of the male: it wants also those black spots on the abdomen.

3. The regulus, or gold-crested wag, is a native of Europe, and of the correspondent latitudes of Asia and America. It is the most of all the European birds, weighing only a single drachm. Its length is about four inches and a half, and the wings when spread out measure little more than six inches. On the top of its head is a beautiful orange-coloured spot, called its crest, which it can hide at pleasure; the rest of the crest is yellow, and it ends in a pretty broad black line; the sides of the neck are of a beautiful yellowish-green; the eyes surrounded with a white circle; the neck and back of a dark green mixed with yellow. In America it associates with the titmice, running up and down the laths of lofty ouths with them, and collecting its food in their company, as if they were all of one breed. It feeds on insects, lodging itself in large trees in a torpid state. It is said to sing very melodiously.

4. The sutoria, or taylor-bird, is a native of the East Indies. It is remarkable for the passion with which it goes about building its nest in order to secure itself and its young, in the most perfect manner possible, against all danger from voracious animals. It picks up a dead leaf, and sews it to the side of a living green stem, and the neck, and its sheathing thread is formed of some fine fibres; the lining is composed of feathers, gossamer, and down. The colour of the bird is light yellow; its length three inches, and its weight only three-sixteenths of an ounce; so that the materials of the nest and its own size are not likely to draw down a habitation depending on so slight a tenure.

5. The hicina, or nightingale, exceeds in size the hedge-sparrow. The bill is brown; the irides are hazel; the head and back pale tawny, dished with olive; the tail is of a deep tawny red; the under parts pale ash-colour, growing white towards the vent; the quills white, the tail-feathers brown and white. The male and female are very similar. This bird, the most famed of the feathered tribe for the variety, length, and sweetness of its notes, is supposed to be migratory. It is met with in Siberia, Sweden, Germany, France, Italy, and Greece. Hasteloupe speaks of it as being in Palestine, and Fryer ascertain its being found about Chulminor in Persia; it is also spoken of as a bird of China, Kamtschatka, and Japan; at which last place they are much esteemed, and sell dear: as they are also at Aleppo, where they are "in great abundance kept tame in houses, and let out at a small rate to such as choose it in the city, so that no entertainment is made in the spring without a concert of these birds."

They are solitary birds, neither uniting into even small flocks; and in respect to the nests, it is very seldom that two are found near each other. They are very different from some low bush or quickset edge, well covered with foliage, for such only this bird frequents; and lays four or five eggs of a greenish-brown. The nest is composed of dry leaves on the outside, mixed with a few hair, lined with hair and down, though not always alike. The female alone sits on and hatches the eggs, while the male not far off regales her with his delightful song; but as soon as the young are hatched, he commonly leaves off singing, and joins in the task of providing for and feeding them. After the young can provide for themselves, the old female provides for a second brood, and the song of the male recommences. They have been known to have three broods in a year, and in the hot countries even four. These birds are often brought up from the nest for the sake of their song. They are likewise caught at their first coming over; but these old birds, though brought to be kept in conveiment, and to sing equally with those brought up from the nest. None but the bilov epipeic, as Mr. Latham remarks, would think of eating these charming songsters; yet we are told that their flesh is equal to that of the ortolan, and they are fattened in Gascony for the table.

6. The medularis, or hedge-sparrow, a well-known bird, has the back and wing-coverts of dusky; the rump and rump-furrows, a greenish-brown; the throat and breast of a dull ash-colour; the belly a dirty white; and the legs of a dull flesh-colour. The note of this bird would be thought pleasant if it were not rendered unpleasant by the approach of winter; beginning with the first frosts, and continuing till a little time in spring. It often repeating the word tit, tit, tit, has occasioned its being called titling; a name it is known by in many places.

7. The plenicurus, or redstart, is somewhat less than the redbreast; the forehead is white; the crown of the head, hind part of the neck, and back, are deep blue-grey; the cheeks and throat black; the breast, rump, and sides, red; and the belly is white; the two middle tail-feathers are brown; the rest red; and the legs are black. The wings are brown in both sexes.

This bird is migratory; coming hither in spring, and departing in autumn about October. It is not so shy as many birds in respect to itself; for it approaches habitations, and frequently makes its nest in some hole of a wall where numbers of people are frequently at home, yet no one meddles with the nest. This bird frequently vags its tail; but does it sideways, like a dog, when he is pleased, and not up and down like the wagtail. It is with difficulty that these feathers are kept in a cage; nor will they submit to it by any means if caught old. Their song has no great strength; yet it is agreeable enough; and they will, if taught young, imitate the notes of other birds, and sing by night frequently as well as in the daytime.

8. The rubecula, or redbreast, is universally known. It abounds in Burgundy and Lorraine, where numbers are taken for the table, and thought excellent. It builds not far from the ground if in a bush; though sometimes it fixes on an out-house, or retired part of some old building. The nest is composed of dried leaves, mixed with hair and moss, and lined with feathers. The eggs are of a dusky white, marked with brown and reddish spots; and are from three to seven in number.

The young, when full-feathered, may be taken for a different bird, being spotted all over. The first rudiments of the red break forth on the breast about the end of August; but it is quite the end of September before they come to the full colour. **Insects** are
their general food; but in defect of these they will eat many other things. No bird is so tame and familiar as this; closely attending the heels of the gardener when he is using his spade, for the sake of worms; and frequently in winter entering houses where windows are open, when they will pick up the crumbs from the table while the family is at dinner. Its familiarity has caused a petty name to be given it in several countries. The people about Bornholm call it Tommi-iden; in Norway, Peter-rummad; the Germans, Thomas-girder; and we, the Robin-red-breast.

9. The emmata, or wheatear, is in length five inches and a half. The top of the head, hind part of the neck, and back, are of a bluish grey; and over the eye a streak of white; the under parts of the body yellowish-white: the breast is tinged with red; and the legs are black. This bird is met with in most parts of Europe, even as far as Greenland, and the Bermudas have also been received from the East Indies. It visits England usually in the middle of March, and leaves us in September. It chiefly frequents heaths. The nest is usually placed under shelter of some turf, clod, stone, or the like, always on the grassy side of a road, in the recess of a seat or the retired rabbit-burrow. It is composed of dry grass or moss, mixed with wool, fur of the rabbit, &c. or lined with hair and feathers. The eggs are from five to eight in number, of a beautiful light green colour, with a deep purple circle at the large end. The young are hatched in the middle of May. In some parts of England these birds are in vast plenty. About Eastbourne in Sussex they are taken in snares made of horsehair placed beneath a long turf, being very timid birds, the motion of a cloud, or the appearance of a hawk, will drive them for shelter into these traps, and so they are taken. The numbers annually ensured in that district alone amount to about 18,000, which usually sell at sixpence per dozen. Quantities of these are eaten on the spot by the neighbouring inhabitants; others are picked, and sent up to the London porkers. Their flesh is very delicate; but as much esteemed in England as the ortolan on the continent. Their food is insects only; though in rainy summers they feed much on earth-worms, whence they are fatter in such seasons.

10. The cyanas, or superb warbler, a most beautiful species, is five inches and a half long. The bill is black; the feathers of the head are long, and stand erect like a full crest; from the forehead to the crown they are of a bright blue; thence to the nape, black like velvet; through the eyes from the bill there runs a line of black; and beneath the eye springs a tuft of the same blue feathers; beneath which, and on the chin, it is of a deep blue, almost black, and feeling like velvet. The hind part of the neck, and upper parts of the body and tail, are of a deep blue-black, the under pure white; the wings are dusky; the shafts of the quills chestnut; the legs are dusky brown; the claws black. It inhabits Van Diemen's Land, the most southern part of New Holland. The female of this species, is discovered to be entirely destitute of all the fine blue, the pale and dark, by which the male is adorned, except that there is a very narrow circle of azure round each eye, apparently on the skin only.

11. The troglodytes, or wren, is a very small species, in length only three inches and three quarters, though some have measured four inches. It generally carries the tail erect. The minute bird is found throughout Europe; and in England it dures our severest winters. Its song is much esteemed, being, though short, a pleasing warble, and much louder than could be expected from the size of the bird. It is divided into nine sorts.

The sylvia builds in low bushes, and lays five pale-green eggs, sprinkled with reddish spots. See Plate Nat. Hist. fig. 271.

Above 150 other species, besides varieties, are enumerated by the ornithologists.

MOTTE, in law-books, signifies court, meeting, or convention, as a war-nodto, burgh, mott, swain-mott, &c.

MOTH. See Phalena.

MOTION, has been defined to be a "change of place," or the act by which a body corresponds with different parts of space at different times. We are principally acquainted with two sorts of motion in the beings that surround us; one is the motion by which an entire body is transferred from one place to another, as if the body of a ship under sail. It is this species of motion which most frequently comes under our observation, and with which we are best acquainted. But, besides this, there is another kind of motion, which, though not so obvious, is yet not less common nor important. This is a motion of the parts of bodies among themselves, which though sometimes the object of our senses, yet in other cases we require the aid of reflection to trace it. It is by this imperceptible motion that plants and animals grow, and by which the greatest number of the compositions and decompositions throughout the globe take place. We may form some idea of this, by observing the continual motion of the light particles which sometimes float about in water, when it is held in the rays of the sun, which proves, that the parts of the water themselves are in constant motion. If we employ our senses, we shall discover that the particles of the most solid bodies are also continually changing their situations. Heat, expans, and cold contracts, the size of all bodies; now, we know from experience, that the temperature of bodies is constantly varying, consequently, the particles must be in continual agitation, in order to adapt themselves to the size of the body.

The communication of motion from one body to another, though a fact with which we are well acquainted, we are equally incapable of accounting for. It is, however, of the utmost importance in mechanics, which is indeed an art derived from the study of its laws. In considering motion, several circumstances must be attended to: 1. The force which impresses the motion. 2. The quantity of matter in the moving body. 3. The velocity and direction of the motion. 4. The time in which the motion is going over this space. 5. The time employed in going over this space. 6. The force with which it strikes another body that is opposed to it. In a mechanical sense, every body, by its inertia, resists all change of state. If at rest, it will not begin to move of itself; and if motion is communicated to it by another body, it will continue to move for ever uniformly, except it is stopped by an external agent. It is true, we do not see any instances of bodies continuing to move for ever, after being once put in motion; but the reason of this is, that all the bodies which we see are acted upon in such a manner, as to have their motion gradually destroyed by friction, or the rubbing of other bodies upon them. For if you diminish the friction by any means, the motion will continue much longer; but as it is impossible to destroy it entirely, it diminishes, and at last destroys, all motions on the surface of the earth. To put a body in motion, therefore, there must be a sufficient cause. These causes are called motive powers, and the following are those generally used in mechanics; the action of men and other animals, wind, water, gravity, the pressure of the atmosphere, and the elasticity of fluids and other bodies.

The velocity of motion is estimated by the time employed in moving over a certain space, or by the space moved over in a certain time. To assign time, we divide it into degrees of this swiftness or velocity, the space covered must be divided by the time. For example: suppose a body moves over 1000 yards in 10 minutes, its velocity will be 100 yards per minute. If we would know the velocity of two bodies A and B, of which A moves over 54 yards in 9 minutes, and B 93 yards in 6 minutes, the velocity of A will be 6 to that of B, in the proportion of 6 (the quotient of 54 divided by 9) to 10 (the quotient of 96 divided by 6).

To know the space run over, the velocity must be multiplied by the time; for it is evident, that if either the velocity or the time is increased, the space run over will be greater. If the velocity is doubled, then the body will move twice the space in the same time; or if the time is twice as great, then the space will be doubled; but if the velocity and time are both doubled, then will the space be four times as great.

It follows from this, that when two bodies move over unequal spaces in unequal times, their velocities are to each other as the quotients arising from these spaces run over by the times. If two bodies move over unequal spaces in the same time, their velocities will be in proportion to the spaces passed over. And if two bodies move over equal spaces in unequal times, then their respective velocities will be inversely as the time employed; that is, if A in one minute, and B in two minutes, run over 100 yards, the velocity of A will be to that of B as 2 to 1. A body in motion must vary instantaneously to some particular point. It may either tend always to the same point, in which case the motion will be in a straight line; or it may be continually changing the point to which its motion is directed, and this will produce a curvilinear motion.

If a body is acted upon only by one force, or by several in the same direction, its motion will be in the same direction in which the forces are tending. If a body is acted upon by a boat which a man draws to him with a rope. But if several powers, differently directed, act upon it at the same time, as it cannot obey them all, it will move in a direction somewhere between them.

This is what is called the composition and
MOTION.

resolution of motion, and is of the utmost importance in mechanics.

Suppose a body A (Plate Miscel. fig. 163) to be acted upon by two forces, and another body in the direction AB, while at the same time it is impelled by another in the direction AC, then it will move in the direction AD; and if the lines AB, AC, are made of lengths proportional to the forces, and the lines CD, DE, drawn parallel to them, so as to complete the parallelogram ABDC, then the line which the body A will describe, will be the diagonal AD; and the length of this line will represent the force with which the body will move. It is evident, that if a body is impelled by equal forces acting at right angles to each other, that it will move in the diagonal of a square; but whatever may be the direction, or degree of force by which the two powers act, the above method will always give the direction and force of the moving body.

It follows from this, that if we know the effect which the joint action of two powers has upon a body, and the force and direction of one of them, we can easily find that of the other. For, suppose AD to be the direction and force with which the body moves, and AB to be one of the impelling forces, then, by completing the parallelogram, the other power AC is found.

Instances in nature of motion produced by several powers acting at the same time, are innumerable. A ship impelled by the wind and tide is one well known. A paper kite, acted upon by the wind and the string, is another.

Motion is said to be accelerated, if its velocity continually increases; to be uniformly accelerated, if its velocity increases equally in equal times.

Motion is said to be retarded, if its velocity continually decreases; and to be uniformly retarded, if its velocity decreases equally in equal times.

If you suppose a body to be put in motion by a single impulse, and moving uniformly, to receive a new impulse in the same direction, its velocity will be augmented, and it will go on with the augmented velocity.

If at each instant that it receives a new impulse, the velocity will be continually increasing; and if this impulse is always equal, the velocity will be uniformly accelerated.

The regularly increasing velocity with which a body falls to the earth, is an instance of accelerated motion, which is caused by the constant action of gravity. To illustrate this, let us suppose the time of descent of a falling body to be divided into a number of very small equal parts; the impression of gravity, in the first small instant, would make the body descend with a proportionate and uniform velocity; but in the second instant, the body receiving a new impulse from gravity, in addition to the first, would move with twice the velocity as before; in the third in- stant, it would have three times the velocity, and so on.

To illustrate the doctrine of accelerated motion, let us suppose that, in the triangle ABC (fig. Miscel. 164), AB expresses the time which a body takes to fall, and BC the velocity acquired at the end of the fall. Let AB be divided into a number of equal parts, indefinitely small, and from each of these divisions suppose lines, as DE, drawn parallel to BC; it is evident from what has been said, that those lines will express the velocities of the falling body in the several respective times; and it is required, using the same reasoning, by which a body falling, in the time expressed by AB, with an uniformly accelerated velocity, of which the last degree is expressed by BC, will be represented by the area of the triangle ABC.

Let us now suppose that gravity ceased to act, and that the body moved during another portion of time, BF, equal to AB, with the acquired velocity represented by BC. As the space moved over is found by multiplying the force by the time, the rectangle CF will represent the space moved over in this second portion of time, which is twice the triangle ABC, and consequently twice the space is moved over with the accelerating velocity in the same time.

But if we suppose gravity still to act, besides the space CF, which it would have moved over by its acquired velocity, we must add the triangle CFI, for the effect of the constant action of gravity; therefore, in this second portion of time, the body moves over three times the space as the first. In like manner, it may be easily seen by the figure, that in the next portion it would move over five times the space; in the next seven times, and so on, in arithmetical progression. And as the velocities of falling bodies are in proportion to the spaces run over, it follows, that the velocities in each instant increase, as the numbers 1, 3, 5, 7, 9, &c.

It follows from this, that the space run over is as the square of the time; that is, in the first instant, a body moves over one time the velocity; in the third, twice the velocity, &c.; for, in the first time, there was but one space run over; the square of 1 is 1; at the end of the second time there are four spaces run over, one in the first, and three in the second; the square of 2 is 4; at the end of the third time there are nine spaces run over; the square of 3 is 9: and so on.

This may be seen in the figure.

It is found by experiment, that a body falling from a height, moves at the rate of 16½ feet in the first second; and, as has been shewn above, acquires a velocity of twice that, or 33½ feet in a second.

At the end of the second second, it will have fallen 63½ feet, the space being as the square of the time; the square of 2 is 4, and 4 times 16½ is 64½. By the same rule you may find, that in the third second it will fall 114¼ feet; in the next 250 feet, and so on. It is to be understood, however, that by this velocity is meant what bodies would acquire, if they were to fall through a space where there was no air; for its resistance considerably diminishes their velocity in falling.

It has already been shewn, that if two forces act uniformly upon a body, they will cause it to move in a straight line; but if one of the forces is not uniform, but either accelerating or retarding, the moving body will describe a curve line. If a ball is projected from a cannon, which, if there was no resistance from the air, and if it was not acted upon by gravity, would cause it to move always in a straight line; but as soon as it leaves the mouth of the cannon, it is acted upon, and makes it change its direction. It then describes a curve, called a parabola. This is the foundation of the theory of projectiles, and the art of gunnery; but it is not now considered to be of so much importance as it formerly was, as it is found that the resistance of the air, and other causes, have so much effect upon projected bodies, that they describe curves very different from what they ought to do according to this theory; and therefore it is much less applicable to practice than otherwise it would be.

The force with which a body moves, or which it would exert upon another body opposed to it, is always in proportion to its velocity, and its mass. This force is called the momentum of the body: for if two equal bodies move with different velocities, it is evident that their forces, or momenta, are as their velocities; and the greater the velocities move over, the greater their force, or momentum; their moments are thus the quantities of matter; therefore, in all cases, their moments must be as the products of their quantities of matter, and their velocities. This rule is the foundation of mechanics.

In consequence of the vis inertiae of matter, all motion produced by one force only acting upon a body, must be rectilinear; for it must receive some particular direction from the power that impressed it, and must retain that direction until it is changed by some other power. Whenever, therefore, we see a body moving in a curvilinear direction, we may be certain that it is acted upon by two forces at least. When one of the two forces ceases to act, the body will move again in a straight line. Thus a stone in a sling is moved round by the hand, while it is pulled towards the centre of the circle, which it describes, by the string: but when the string is let go, the stone flies off in a tangent to the circle.

Every body moved in a circle has a tendency to fly off from its centre, which endeavour of receding is called the centrifugal force; and it is opposed to the centripetal force; or that which, by drawing bodies towards the centre, makes them revolve in a curve. These two forces are called together centripetal forces.

The centre of gravity of a body is that point about which all the parts of a body do go in any situation exactly balance each other.

Hence, if a body is suspended or supported by this point, the body will rest in any position in which it is put. Also, whatever support bears the weight of the whole body; and while it is supported, the body cannot fall. We may therefore consider the whole weight of a body as centred in this point.

The common centre of gravity of two or more bodies is the point at which they would equilibrate, or rest, in any position. If the centre of gravity of two bodies, A and B, (Plate Miscel. fig. 165) is connected by the
right line AB, the distances AC and BC, from the common centre of gravity C, are reciprocally as the weights of the bodies A and B, that is AC : BC = B : A.

In the direction from the centre of gravity of a body, perpendicular to the horizon, it is called the line of direction; because it is the line that the centre of gravity would describe if the body fell freely.

It is the property of this line, that while it falls within the base upon which the body stands, the body cannot fall; but if it falls without the base, the body will tumble. Thus the inclining body ABCD, (fig. 160) whose centre of gravity is E, stands firmly on its base CDIIK, because the line of direction EL falls within the base. But if a weight, as ABII, is laid upon the top of the body, the centre of gravity of the whole body and weight together is raised to L: and then, as the line of direction LD falls without the base at D, the centre of gravity is not supported, and the whole body and weight will tumble down together.

It appears the absurdity of people’s rising hastily in a coach or boat, when it is likely to overseat; for by that means they raise the centre of gravity so far as to endanger throwing it quite out of the base, and if they do, the vehicle will inevitably tumble. Whereas, had they clapped down to the bottom, they would have brought the line of direction, and consequently the centre of gravity, farther within the base, and by that means saved themselves.

The broader the base, and the nearer the line of direction is to the middle or centre of it, the more firmly does the body stand. On the contrary, the narrower the base, and the nearer, or the line of direction is to the side of it, the more easily may the body be overthrown, a less change of position being sufficient; to remove the line of direction out of the base in the latter case than in the former. And hence it is, that a sphere is so easily, as it were, rolled upon a horizontal plane; and that it is so difficult, if not impossible, to make things which are sharp pointed to stand upright on the point.

What has been said, it plainly appears, that if a plane CD on which a heavy body is placed, was elevated at C, the body would slide down upon the plane, whilst the line of direction falls within the base; but it would stand, or the line of direction is to the side of it, the more easily may the body be overthrown, a less change of position being sufficient to remove the line of direction out of the base in the latter case than in the former.

Hence it is, that a sphere is so easily, as it were, rolled upon a horizontal plane; and that it is so difficult, if not impossible, to make things which are sharp pointed to stand upright on the point.

The line of direction falls within the base of our feet, we stand, and most firmly when it is in the middle; but when it is out of that base, we immediately fall. And it is not only pleasing, but even surprising, to reflect upon the various methods and postures which we use, to retain this position, or to recover it when lost, without our being sensible of it. Thus we bend our bodies when we rise from a chair, or when we go up stairs; and for this purpose a man leans forward when he carries a burden upon his back, and backward when he carries it on his breast, and to the right or left side as he carries it on the opposite side.

If a body is suspended freely from different centres its centre of gravity will be in the intersection formed by lines drawn from those centres perpendicular to the horizon. Hence we obtain an easy practical method of finding the centre of gravity of any irregular plane figure. SUSPEND it by any point, with the plane perpendicular to the horizon, and from the points where it hangs, and draw a line upon the body where the string passes over; do the same for any other point of suspension, and where the two lines intersect must be the centre of gravity; for the centre of gravity being in each line, it must be at the point where they intersect.

Motion, spontaneous or muscular, is that performed by the muscles at the command of the will.

Motion, natural or involuntary, that effect, without any such command, by the mere mechanism of the parts, such as the motion of the heart, pulse, &c.

Motion, intestinal, the agitation of the particles of which a body consists.

Motion, in music, the manner of beating the measure, to hasten or slacken the time of the words or notes.

MOUVEMENT, in mechanics, a machine that is moved by clockwork. See Clockwork.

MOULDINGS. See Architecture.

MOUNTAINS. Elevations consisting chiefly of clay, sand, or gravel, are called hills. Those which consist chiefly of stone are called mountains. Mountains are divided into primeval, that is, of equal date with the formation of the globe, and secondary or alluvial. Among primeval, those of granite hold the first place. The highest mountains and most extensive ridges throughout the globe are of that kind; as the Alps and Pyrenees in Europe; the Altiscanah, Uralian, and Caucasus, in Asia; and the Andes, in America. The highest of them never contain metallic ores; but some of the lower contain ores of copper and tin. The granite next the ore always abounds in mica. Petrifactions are never found in these primeval mountains.

That the formation of these mountains preceded that of vegetables and animals, is justly inferred from their containing no organic remains, either in the form of petrifaction or impression. Naturalists are agreed, that granites were formed by crystallization. This operation probably took place after the formation of the atmosphere, and the gradual separation of the dry bed of the ocean, which is now the dry land appeared. For, by means of the separation of the aëridiform fluids which constituted the atmosphere, the evaporation of part of the water into the atmosphere, and the gradual retreat of the remainder, the various species of earths, before dissolved or diffused through this mighty mass, were disposed to coalesce; and among these the silicious must have been the first, as it is the least soluble; but as the silicious earth has an affinity to the other earths with which it was mixed, some of these must have united in various proportions, and thus have formed, in distinct masses, the sandstone, siltstone, and mica, which compose the granite. Calcareous earth enters very sparingly into the composition of this stone; but as it is found in school, which is frequently a component part of granite, it follows that it must be one of the primitive earths, as derived from the primeval ocean, as some have supposed. Quartz can never be supposed to be a product of fire; for

in a very low heat it bursts, cracks, and loses its transparency, and in the highest degree of heat that we can produce, is insubstantial, so that in every essential point it is different from the other parts of granite, which we have compared it. As granite contains calcareous masses, we may conclude, that all the simple earths are original. This, however, is no proof that they are in reality simple and uncompounded; or that they are simples, but they must be considered as such in the present state of our knowledge. Though water undoubtedly dates from creation, yet late experiments have shown it to be a compound, as was formerly stated.

Mountains which consist of limestone or marbles of a granular or scaly texture, and not disposed in strata, seem also to have preceded the creation of animals, for no organic traces are found in them. Some of those which consist of argillaceous stones, and some of the silicious, contain also no organic remains. These often consist of parallel strata of unequal thickness; and the lower are harder and less thick than the upper, and therefore seem to have been formed earlier than the upper.

Alluvial mountains are evidently of posterior formation, as they contain petrifactions and other vestiges of organic substances, and these are always stratiﬁed.

Mountains, as to structure, are entire, stratified, and confused. Entire mountains are formed of huge masses of stone, without any regular fissures, and are mostly homogeneous.

They consist chiefly of granite, sometimes quartz, schistus, felspar, sandstone, limestone, gypse, porphyry, or trap. Some in Sweden and Norway consist of iron ore.

The stratified mountains are those whose mass is regularly divided by joints or fissures; these are called horizontal, rising, or dipping. Homogeneous stratified mountains consist chiefly of stones of the argillaceous genus, or of the ﬁssile compound species of the silicious genus, as metallic rock; sometimes of limestone of a granular or scaly texture, in which vestiges of animal or vegetable life are preserved upon the argillaceous or silicious strata; sometimes the argilaceous are covered with masses of granite, sometimes of lava. These mountains, particularly those of Greece, metallic rock, and homogenous, are the chief seat of metallic ores. When covered with limestone, the ore is generally between the limestone and the argilaceous stones. These ores are in veins, not in strata. Petrifactions are found upon, but not in, these mountains.

Heterogeneous, or compound stratified mountains, consist of alternate strata of various species of stones, earths, sands, &c. The limestone here is always of the laminar, and not of the granular or scaly kind; and when it contains any ore, it is placed between its lamine. Stones of the silicious genus seldom form strata in these mountains, except laves; but the strata are frequently interrupted by silicious masses, as Jasper, porphyry, &c. Coal, bitumen, petrifactions, and organic impressions, are found in these mountains; also salts and calamine.

There are other mountains, which cannot properly be called stratified, as they consist of three immense masses, the lowest granite, the middle limestone, and the upper limestone. Metallic ores are found in
the argillaceous part, or between it and the limestone.

Confused mountains consist of stones heaped together without order, their interspaces filled with clay, sand, and nica. They scarcely ever contain any ore.

Besides these, there are many mountains in different parts of the world, which derive their origin from volcanoes; but of these it will be necessary to treat in a succeeding article.

The height of mountains is usually calculated by means of the barometer. For this purpose two columns of mercury, or barometers, are prepared, and one is kept at the foot of the mountain while the other is carried to its summit. The degree of heat, if not equal, is reduced by calculation to an equality, and for this purpose a thermometer is attached to each of the barometers. The degree of height to which both are reduced is 55°, if, however, either of the barometers stands at 30 inches, and the annexed thermometer at 55°, no reduction is to be made in the determination of the barometer; but if either of them is at 30°, and the thermometer below 55°, we must add the expansion of the mercury in the barometer which a temperature at the height of 35° should produce, to the expansion above 55°, and must abstract the degree of expansion which it gains by that heat. Every degree of Fahrenheit's scale produces an expansion of 0.0034 of the barometrical column; when the barometer is at 35°, and the thermometer at 11°, we must add the increment in the former, and subtract the latter case, eleven times that number from the barometrical height. In the same manner it may be calculated, whatever is the height of the barometer. When this matter is ascertained, the height is easily found by comparing the two barometers, and calculating the density of the air in the higher regions according to the principles of geometrical progression.

The highest mountains are those which are situated at or near the equator; and the Andes are generally allowed to be the highest of these. Catopoxi, one of the Andes, which rises above 15,000 feet, was discovered by a French academician, was found to be some miles above the level of the sea; whereas the highest point of the Alps is not above a mile and a half. Mount Caucasus approaches nearest to the height of the Andes, of any of the Asiatic mountains. The Peak of Teneriff, which has been so much celebrated, is about a mile and a half in height. It is an extraordinary circumstance, that the moon, which is a body so much smaller than our earth, should have been thought to exceed it in the irregularities of its surface; some of the mountains in that planet being formerly supposed to exceed nine miles in height: but Dr. Hertzel has proved that the highest of them is not equal to one mile.

The line of congelation, or of perpetual frost, on mountains, is calculated at 13,400 feet, at or near the equator; at the entrance of the temperate zone, or on the plains, and towards the pole, it is calculated at 8,000 to 10,000 feet; in the 41st degree, 10,000 feet; in the 52d, 7,540 feet. On the Andes, vegetation ceases at 14,697 feet; and on the Alps, at 9,958. The air is so dry in these elevated situations, that M. d'Arcet observed, that on the Pyrenees, salt tarfar remained dry for an hour and a half, though it immediately moistened in the same temperature at the bottom of the mountain.

Mounting, in military affairs, signifies going upon duty. Thus, mounting a breach, is running up to it; mounting the guard, is going upon guard; and mounting the trenches, is climbing over or into the trenches; but mounting a cannon, mount, &c. is the setting it on its carriage, or the raising its mouth.

MOUNTAIN. See ANATOMY.

MUCILAGE, a glutinous matter obtained from vegetables, transparent and tasteless, soluble in water, but not in spirit of wine. It chiefly consists of carbon, hydrogen, and a small quantity of oxygen. See GLUTEN.

MUCILAGINOUS GLANDS. See ANATOMY.

MUCOR, in botany, a genus of the order of fungi, in the cryptogamous class of plants. The fungus has vesicular heads supported by foot-tails. There are 17 British species; the most remarkable of which are: 1. The spherical, which is a common mould, growing upon rotten wood, and sometimes upon decayed plants and mosses. The stalks of this are generally black, about a line in height, bearing each at the top a spherical ball, about the size of a pin's head; its coat or rind is covered with a grey powder, and containing within a black or fuscous spongy down. The coat bursts with a ragged, irregular margin. 2. The lichenoides, or little, black, putrid-pus. This fungus grows in groups near to each other, in masses of the backs of old trees, and upon old park-pales. The stalks are black, about two or three lines in height, bearing each a single head, sometimes a double or treble one, of the size of mustard or poppy seeds, of a roundish figure at first, but when burst, often flatish or truncated, and of a black colour. The internal powdered down is black, with a tinge of red. 3. The annulatus, a common grey mould, grows on bread, fruits, plants, and other substances, in a putrid state. It grows in clusters; the stalks a quarter of an inch high, pellicid, hollow, and cylindrical; supported by the feathery stalk, at first transparent, afterwards dark-grey; which bursts with elastic force, and ejects small round seeds discoverable by the microscope. 4. The glaucus, or grey cluster-headed mould, is found on rotten apples, melons, and other fruits; as also upon decayed wood, and the stalks of wheat. These are of a pellicid grey colour; the stalks are generally single, supporting a spherical ball, which, when burst, sends forth a spongy powder, covered with numerous, fine, moniliform, necklace-like radii. 5. The crustaceus, or fingered mould, is frequent upon corrupted food of various kinds. It is of a white aequous colour; the stalks single, each supporting at the top four or five necklace-like radii, diverging from the same point or centre. 6. The septicus, or yellow frothy mould, is found on the leaves of plants, such as ivy and beech, &c. sometimes spreading externally upon the tan or bark in hot-houses. It is of no certain size or figure, but of a fine yellow colour, and a substance resembling at first cream beaten up into froth. In the space of 24 hours, it becomes grey-brown, because so dry, and full of a powdy adhering to downy threads. The seeds under the microscope appear to be globular. Haller ranks it under a new genus, which he terms fuligo; the characters of which are, that the plants contained under it are sot, and like butter at first, but soon change into a black sooty powder.

MUCOUS ACID. See SALICATIC ACID.

MUCOUS GLAND. See ANATOMY.

MUCUS, a fluid secreted by certain glands, and serving to lubricate many of the internal cavities of the body. In its natural state it is generally limpid and colourless; but from certain causes, will often assume a thick consistence and whitish colour like pus. As it is sometimes of very great importance in medicine to distinguish the two fluids from each other, this was lately proposed as the subject of a prize disputation by the Esculapian Society of Edinburgh. The prize was gained by Mr. Charles Darwin, student of medicine from Litchfield.

The conclusions drawn from his experiments were, 1. Pus and mucus are both soluble in the vitriolic acid, though in very different proportions, pus being by far least soluble. 2. If the putrid pus is exposed to the action of these compounds, it decomposes itself into a mucus thus separated, both in the mixture, or forms large floculi in it; whereas the pus falls to the bottom, and forms, on agitation, an uniform turbid mixture. 3. Pus is diffusible through a diluted vitriolic acid, though mucus is not. The same also occurs with water, or with a solution of sea-salt. 4. Nitric acid dissolves both pus and mucus. 5. This latter produces a precipitate, and the fluid above becomes clear and green, while water and the solution of mucus form a turbid dirty-coloured fluid. 6. Alkaline lixivium dissolves, though sometimes with difficulty, mucus, and generally pus. 6. Water precipitates pus from such a mixture, but does not mucus. 7. Where alkaline lixivium does not dissolve pus, it still distinguishes it from mucus, as it does not produce its different plant to the solution of pus. 8. Coagulable lymph is neither soluble in concentrated nor diluted vitriolic acid. 9. Water produces no change on a solution of serum in alkaline lixivium, until after long standing, and then only a slight sediment appears. 10. Corrosive sublimate coagulates mucus, but does not pus.

From the above experiments, it appears that strong sulphuric acid and water, diluted sulphuric acid, and caustic alkaline lixivium and water, will serve to distinguish pus from mucus; that the vitriolic acid can separate it from coagulable lymph, and alkaline lixivium from serum. Hence, when a person has any pain or matter, excreting from the sores of which he wishes to ascertain, let him dissolve it in vitriolic acid, and in caustic alkaline lixivium; and let him add pure water to both solutions. If there is a fair precipitation in each, he may be assured that some pus is present. But if there is a precipitation in neither, it is a certain test that the mixture is entirely mucus. If the matter cannot be made to dissolve in alkaline lixivium by time and weather, we have also reason to believe that it is pus.

MUCUS, NASAL: this name is given to a liquid which is secreted in the cavities of the nose, and is discharged outwardly, either by the nostrils in the form of drops, or in that of masses more or less thick; or by the faucets.
when it descends by the posterior part of the nasal cavities, in which it is thrown out by spitting. This liquid is separated from the blood by the arteries, and appears to be formed in particular crypts, which we find abundantly in the nasal cavities. It is also collected also from all the frontal sinuses. It is also mixed with the lachrymal juice, which descends by the channel which pases through the eye or oculus, and dilutes the thickened nasal mucus.

We must particularly consider both the abundance and the characters of this liquid in the catarh, improperly called catarh of the brain, in which the nasal mucus is separated in larger quantity, and remains a longer time in its ducts. "It is," says M. Forcroy, "especially under this circumstance, that citizen Vaquinel and myself have examined it, as we then procured it with great facility. We have also availed ourselves of the considerable discharge of mucus which is produced by the contact of the oxidated muriatic acid gas, in order to obtain a sufficient quantity of it for the experiments adapted to that end, and will acquiesce with its nature. It has several times happened to citizen Vaquinel, who is very sensible to the action of the oxidated muriatic acid gas, that he has collected by its effect of grammes of it in less than an hour. Any means of these circumstances we have been enabled to determine its nature in a considerably exact manner. It is known that this liquid is very abundant in children, that it is a little heavier, turns yellow, and adheres to most bodies, even the most punished.

The nasal mucus is at first liquid, clear and transparent, a little viscid and adhesive, without smell, of a salpy and acrid taste, which irritates the most delicate part of the skin; it is then really the phlegma vitium of the arteries. When exposed to the air and to the fire, it comport itself in the same manner as the tears, from which it differs only by the abundance of its praeuna, which is thicker, and frequently more coloured. It affords crystals of carbonate of soda, of soda in the state of carbonate, and of phosphates of lime and of soda; the last are much more abundant than the first, and are especially united with the yellow flowers green, by its sall: we also find in it, an animal matter which is not albuminous, but quickly becomes thick and concrete by the oxigen of the air and of the oxidated muriatic acid; it then acquires opacity, and a yellow or greenish colour, swells considerably, and becomes filled with bubbles by the action of fire, leaving but little residue upon the ignited coal. This animal matter, which is much abundant than the tears, appears to be of the same nature in both.

This liquid, being always exposed to the air, which continually passes through the nostrils, is continually thicker, more viscid, and more adhesive, than the tears; and the carbonate of soda which it contains, whilst the latter contains only soda, announces that the air departs it in a part of the carbonate of soda, and that it is reduced out of the lungs. Consequently, it then renders the solutions of bar, tellurium, and of lime, very sensibly united. In the nostrils, the heat of the plan, especially in catarh, and the air, which is necessarily a little thick, contribute also to thicken it. The mucus of the nasal humour, when it becomes thick in the air, frequently assumes in it the form of small, dry, bright, and, as it were, mucous plates. If it has dripped in very thin layers, it quickly resembles those bright and light marks which smuts leave behind it on any solid body whatever it may crawl. The nasal mucus experiences no real putrefaction in the air; we should almost be induced to say that it was unalterable and improuctible, when we see it remain without changing any bad smell, even in the midst of water, and at a considerably elevated temperature. However, this property of preservation does not extend so far as to communicate itself to other bodies that are immersed in it.

Water does not dissolve the mucus of the nose. It is known that this matter remains viscid in that fluid, and that it cannot be diluted in water without much difficulty, even without changing any bad smell, even in water, by the midst of mucus, and at a considerably elevated temperature. It is known that this insolubility is owing to the fixation of the oxygen. Neither has it the property of rendering oils miscible with water, nor of effecting their suspension by turbidation, as a separate and delicate liquid. It is on this account that when we wash, or even boil, this thick humour in water, the salts which it contains are dissolved and separated, without affecting the mucus which constitutes its base.

The acids thicken the nasal mucus when they are concentrated and employed in small proportions; but when we add a larger quantity, they redissolve and give it different shades of color. The sulphuric acid turns it purple, and renders it very liquid, forming however some flakes in it which sink to the bottom. The nitriue acid, when rather strong, dissolves it also into yellow colour. The muriatic acid is that which gives its solution the most easily and the most completely of all, giving it a violet-colour. The alkali, or earthy salts, do not cause it to undergo any alteration, nor do they dissolve it. The mucus of the nostrils being especially distinguished from all the other animal liquids by the viscid mucus which it contains in considerable abundance, it is evidently from the presence of this principle that we seek to use its function which it performs in the animal economy. Besides the kind of evacuation, sometimes very abundant, which it procures; and the proportion of the evacuated matter compared with that of the other excreta, it contains much of the other body, which it carries out of the body; this liquid maintains the softness of the membraneous sides of the nasal cavities, and prevents that dryness which the air gets in continual streams through these cavities tends to produce in them. It modifies the too great sensibility of the nervous pipe and which are spread out upon the effusive membrane; it stops and cures the odoruous blood, and their too great activity; it purifies the air that is inspired, by taking from it the putrefactive particles which it carries along with it, and which would be more injurious in the lungs. Being always contained in a lot, hot, and not pure, these circumstances which would so eminently promote putrefaction, protect nature has given it a property which opposes the scum which would have exposed man and the animals to a multitude of dangerous vitious and nuisances.

It is known that the mucus of the nostrils is used in preparing various medicines, in consuming various properties, in the most affections. It thickens, becomes yellow, orange-coloured, or greenish, frequently tinged with a very lively green cast by drying upon it; it can form places, the secretion of the presence of copper; and sometimes it exhibits a nauseous or least smell. In some affections it becomes so acrid that it seems to corrode the membrane of the nostrils, and produces evolutions round their orifices, as well as upon the upper lip. Lastly, it is sometimes liquid like water, at othersropy like oil: in several cases thick, viscid, and always transparent, like jelly; in other circumstances, congecent, and white, yellow, or green, like a perquisite humour. None of these changes have yet been chemically examined, and hardly even has the attention which they deserve been bestowed upon them.

MUFTI, or MUPPTI, the chief of the ecclesiastical order, or primatie, of the mamluk religion. The authority of the mufti is very great in the Ottoman empire; for even the sultan himself, if he would preserve any appearance of religion, cannot, without hearing his opinion, put any person to death, or so much as inflict any corporal punishment.

In all actions, especially criminal ones, his opinion is required by giving him a writing, in which the case is stated; the affected names, which he subscribes with the words, He shall, or shall not, be punished. Such outward power is paid to the mufti, that the grand seignior himself rises up to him; and advances seven steps to meet him, when he comes into his presence. The election of the mufti is solely in the grand seignior, who presents him with a vest of rich sables, &c. If he is convicted of treason, or any great fault, he is put into a house of correction for that purpose in the Seven Towers at Constantinople, and sound to death.

MUGGLETIONS, a religious sect, which arose in England about the year 1657; so denominated from their leader Lodowick Muggleton, a journeyman tailor, who, with his associate Reeves, asserted, that they were the two last witnesses of God that should appear before the end of the world.

MUGIL, mullet, a genus of fishes of the order Amonoidei. The generic character is, lips membranous; the hinder orca cutaneous within: teeth none; at the corner of the mouth an inflated callus; gill-membrane with six curved rays; body fleshy; scales large; dorsal fins two.

1. Mugil cephalus, common mullet. This fish, the most numerous of the ancient Romans, is a very common inhabitant of the Mediterranean and northern seas, frequenting chiefly the shallow parts near the shores, and feeding on the smaller kind of worms, and small fish. Its average length is from 12 to 16 inches, and the colour blueish-grey, darker on the back, and silvery on the abdomen; the sides are marked, like those of the grayling, with several dusky stripes, according to the rows of scales,
which are large and rounded; the fins are blueish; the dorsal fin, which is placed on the middle of the back, consists of four very strong rays; the second dorsal fin is placed opposite the anal, and has only soft rays; the base of the dorsal and anal fin, as well as the tail, is scaly, and the tail is forked or lunate.

The mullet is found not only in the European seas, but in the Indian and Atlantic oceans. It is observed to assemble frequently in small schools near the shore, to gorge itself with food, burrowing into the soft mud, and leaving the trace of its head in the form of a round hole.

In the spring and early summer months, this fish, like the salmon, ascends rivers to a considerable distance; and when preparing for these expeditions, is observed in schools near the surface of the water, at which time the fishermen endeavour to avail themselves of the opportunity of surrounding them with their nets, which the fish are said to show great address in escaping from.

The mullet is considered as an excellent fish for the table, though not a fashionable one on account of its small size. Bloch informs us, that it is generally eaten with the addition of oil and lemon-juice. The size is often prepared into an inferior kind of caviar, called botargo, by drying and salting it; in which manner also the fish itself, in plentiful seasons, is occasionally preserved. See Plate Nat. Hist. fig. 272.

2. Mugil crenilabis, crenated mullet. Size of the common mullet; length about twelve inches; colour greenish, but varies rather large, and marked by a dusky streak; upper lip gaping, lower incised within, and both lips crenulated on the edges; has glaucous, white, the pectoral marked at the base by a round black spot; tail forked: native of the Red Sea.

There are seven other species.

MUG-WORT, in botany. See ARTEMESIA.

MUHLEBERGIA, a genus of the class and order triandra dioica. Has two ovules; one, to each, lateral; corolla two-valved. There is one species, a grass of America.

MUÍD, a large measure in use among the French, for things dry; this vessel is no measure, but an estimation of several other measures, as the septier, minot, minot, busel, &c.

Muid is also one of the nine casks, or regular vessels, used in France, to put wine and other liquors in. The mud of wine is divided into two demi-muids, four quarter-muids, and eight half-quarter-muids, containing 30 septiers.

MUG-BERRY. See MORUS.

MULE, in zoology, a mongrel kind of quadruped, usually generated between an ass and a mare, and sometimes between a horse and a she-ass; but the signification of the word is commonly extended to every kind of animal produced by a mixture of two different species. There are two kinds of these animals: one from the he-ass and mare, the other from the horse and the she-ass. We call them indifferently mules, but must distinguish them by proper apppellations. The first kind are the best and most esteemed, as being larger, stronger, and having least of the ass in their disposition. The largest and stoutest asses, and the fairest and finest mares, are chosen in those countries where these creatures are most in use; as in Spain, Italy, and Flanders. In the last especially, they succeed in having very stately mules from the size of their mares, some of them ten and some hands high, which are used as the horses in the army. But since the Low-countries are no longer under the dominion of Spain, they breed fewer mules. These creatures are very much commended for their being stronger, surer-footed, going easier, being more cheaply maintained, and lasting longer, than horses. They are commonly of a black brown, or quite black, with that shining list along the back and cross the shoulders which distinguishes asses. In former times they were much more common in this country than at present, being often brought over in the days of popery by the Italian princes. They continued longest in the service of millers, and are yet in use among them in some places, on account of the great loads they carry on their back. As they are capable of being trained for riding, bearing burdens, and for draught, there is no doubt that they might be made serviceable in different services.

But they are commonly found to be vicious, stubborn, and obstinate to a proverb; which whether it occurs or is produced by the ill usage they meet with, is a point not easily settled. Whatever may be the case of these asses, it is allowed that mules are larger, fairer, and more serviceable, in mild than in warm climates. In the British American colonies, both on the continent and in the West Indies, they are much more used and esteemed; so that they are frequently sent to them from hence; suffer less in the passage, and die much seldomer, than horses; and commonly yield, when they arrive, no inconsiderable profit.

It has commonly been asserted, that animals produced by the mixture of two heterogenous species, are incapable of generating, and thus perpetuating the monstrous breed: but this, that the learned M. Buffon, is now discovered to be a mistake.

MULIES, among gardeners, denote a sort of vegetable monsters produced by putting the barley fecundans of one species of plant on the capsule of another. It is generally said, that the Romans practised a singular refinement in luxury, by first bringing the fish alive to the table in a glass vessel, in order that the guests might enjoy the pleasure of contemplating the beautiful and various characters of the fish, and the splendid colours during the time of its gradual expiration; after which it was prepared for their repast.

Mullus surmuletus, striped mullet, of similar size and general appearance with the preceding, but marked on each side by two and sometimes three longitudinal yellow stripes: native of the Mediterranean, but found occasionally in the Atlantic and other seas; usually on the smaller fishes, worms, the Romans practised a singular refinement in luxury, by first bringing the fish alive to the table in a glass vessel, in order that the guests might enjoy the pleasure of contemplating the beautiful and various characters of the fish, and the splendid colours during the time of its gradual expiration; after which it was prepared for their repast.

Mullus indicus, Indian mullet. Size and habit of the common or red mullet; colour extremely beautiful in the living fish, but fading very soon after death; upper part of the head and back dark changeable purple, growing faint on the sides, which are marked by a few longitudinal azure and golden bands, and by other occasion the fish being turned on each side; the first situated about the middle of the body, smallish, and of an opaline or changeable golden and white colour; the second situated near the tail, larger; and of a dark purple; abdomen white; dorsal fin
purple, streaked with light blue; pectoral and anal pink-colour: native of the Indian seas: observed by Dr. Russel near Vigapata:- inferior as a food to the red mullet, and not much esteemed.

4. Mullus barbatus, inhabits the European, Mediterranean, and Pacific seas: body, when deprived of its scales, red. Nothing can be more beautiful than the colours of this fish, when in the act of dying; and nothing more delicious than its flesh. The Romans held it in such repute, that prodigious sums were given for them: they were frequently bought at their weight in pure silver. See Plate Nat. Hist. fig. 273. There are two other species.

MULTIPLIER, in geometry, is applied to those figures which have more than four sides or angles, more usually called polygons.

MULTINOMIAL, or Multinomial Roots, in mathematics, such roots as are composed of many names, parts, or members: as, \( a + b + d + c \), &c. See Root.

MULTIPLE, in Arithmetic, a number which comprehends some other several times, thus \( a \) is a multiple of \( 2 \).

MULTIPLE RATIO, or Proportion, is that which is between multiples. If the less term of the ratio is an aliquot part of the greater, the ratio of the greater to the less is called multiple, and, that of the less to the greater, submultiple. A submultiple number is that contained in the multiple; thus, the numbers 1, 2, and 3, are submultiples of 9. Dupile, triple, &c. ratio, as also submultiples, submultiples, &c. are so many species of multiple and submultiple ratio. See Ratio.

MULTIPLICATION. See Arithmetic, and Algebra.

MULTIPLYING GLASS. See Optics.

MUM, a kind of malt liquor, much drunk in Germany, and chiefly brought from Brunswick, which is the place of most note for making it.

MUMMY. See Embalming.

MUNCHausia, a genus of the class and order Polyplacodida Polyplacida. The ca-
yx is six-rayed; claws; staminia in six bade; pistil superior. There is one species, a tree of Java.

MUNICIPAL, in the Roman civil law, an appellation which signified invested with the rights and privileges of Roman citizens. Thus the municipal cities were those whose inhabitants were capable of enjoying civil offices in the city of Rome.

Munipal, among us, is applied to the laws that obtain in any particular city or province; and those are called municipal officers who are elected to defend the interest of cities, to maintain their rights and privileges, and to preserve order and harmony among the citi-
gens; such as mayors, sheriffs, &c.

MUNTINGIA, a genus of the class and order Polytropia monogyne. The calyx is five-parted; corola five-petalled; berry five-
ecled; seeds many. There is one species, a shrub of Mexico.

MURENA, a genus of fishes of the order Apodai. The generic character is, body oval-shaped; pectoral fins none; spiracle on each side the neck.

1. Murana, Roman murena. This fish, the celebrated favourite of the ancient Romans, who considered it as one of the most luxurious articles of the table, is found in considerable plenty about several of the Mediterranean coasts, where it arrives at a size at least equal, if not superior, to that of an eel. It is of a dusky greenish-brown, rather thickly variegated on all parts with dull-yellow subangular marks or patches, which are disposed in a somewhat different manner in different individuals, and are generally scattered over with smaller speck-
lings of brown, the whole forming a kind of obscurely reticular pattern. The murena is capable of living with equal facility both in fresh and salt water, though principally found at sea. In its manners, it much resembles the eel and the conger, being extremely voc-
acious, and preying on a variety of smaller animals. The ancients, who kept it in reservoirs appropriated for the purpose, are said to have sometimes tamed it to such a degree as to come at the signal of its master in order to receive its food. Pliny records a most disgusting and barbarous instance of tyranny practised by one Vedius Pollio, who was in the habit of causing his offending slaves to be thrown into the sea in which he killed his murena: expressing a savage delight in thus being able to taste in an improved state their altered remains. The emperor Augustus, according to Seneca, honoured this man with his presence at one of his entertain-
ments; when a slave happening to break a valuable chrysal vase, was immediately or-
dered to be thrown to the murena; but the poor boy, lying to the feet of Augustus, re-
qusted rather the death than that he should be made the food of fishes. The emperor,
being informed of this extraordinary mode of punishment, immediately ordered all the chrysal vessels in the house to be broken before his face, and the ponds of the barba-
rous owner to be completely filled up; at the same time giving the slave his freedom, but sparing the life of the offender in considera-
tion of former friendship. See Plate Nat. Hist. fig. 276.

2. Murena obis, spotted murena. Observed by Forskål; native of the Red Sea; has a rising callus between the eyes, gold-
colouraid rings, upper lip shorter than the lower, and the dorsal and anal fins united at the tail. See Plate Nat. Hist. fig. 277.

3. Mureana catenata, chain-striped mu-
rena. This species, of which the individuals hitherto described appear to be of the size of a smallish eel, is of a brown colour, crossed by large chalikide white bands, somewhat irregular in their form on different parts of the animal, and marked by numerous brown spots and freckles. This fish is a native of Surinam.

4. Murena reticulata, reticulated murena. In size and general form, this resembles the preceding species, but differs in colours and in the disposition of the dorsal fin, which commences immediately at the back of the head, and is continued round the tail, where it unites with the vent-fin. Native of the Indian seas.

5. Murena conger, conger eel; inhabits the European seas and rivers; is extremely voracious, feeding on other fish, crabs in their soft state, and particularly crabses. It grows to a vast size. See Plate Nat. Hist. fig. 274. There are four other species.

MURDER, or Murther. See Homi-
cide.

MUREX, in natural history, a genus of univalve or simple shells, without any hinge, formed of a single piece, and beset with tub-
bercles or spines. The mouth is large and oblong, and has an expanded lip, and the clavicle is rough.

The clavicle of the murex is in some spec-
ies elevated, in others depressed; and the mouth is sometimes dentated, and at others smooth; the lip also in some is digitated, in others elated, and in some laciniated; and the columella is in some smooth, in others rugose.

Murex, in zoology, a genus of insects be-
longing to the order of Verses testacea. This animal is of the snail kind: the shell consists of one spiral valve, rough, with men-
braunaneous furrows; and the aperture termi-
nates in an entire canal, either straight, or somewhat ascending. There are 60 species, particularly distinguished by peculiarities in their shells, &c. See Plate Nat. Hist. figs. 277, 278.

In the accounts of a Spanish philosopher it is mentioned, that on the coasts of Guayquil and Guatimala, in the month of July it is also
found. The shell which contains it adheres to the rocks that are washed by the sea. It is of the size of a large walnut. The liquor may be extracted two ways: some kill the animal after they have driven it out of the shell, then press it with a knife from head to tail, separate from the body the part where the liquor is collected, and throw away the rest. When this operation, after being repeated on several snails, has afforded a cer-
tain quantity of fluid, the thread intended to be dyed is dipped in it, and the process is finished. The colour, which is at first of the whiteness of milk, becomes afterwards green, and is not purple till the thread is dry. Those who disapprove of this method draw the fibre partly out of the shell, and, squeezing it, make it yield a fluid which serves for dyeing: they repeat this operation four times at differ-
ent intervals, but always with the same success. If they continue it, the fish dies. No colour at present known, says the Abbé Raynal, can be compared to this, either as to lustre, live-
feness, or duration. It succeeds better on cold than on hot.

MURIAT, green sand of Peru. This ore, which was brought from Peru by Don-
beay, is a grass-green powder, mixed with grans of quartz. When thrown on burning coals, it communicates a green colour to the flame. It is soluble both in nitric and mu-
ricic acids without effervescence. The so-
lution is green. This mineral was first proved to contain mucric acid by Berthollet. Af-
terward Proust analyzed it. But Vaunquen announced that he considered it merely as an oxide of copper mixed with common salt. However, a subsequent examination con-
vinced him that his opinion was unfounded; and that the mineral was really a carbonat, as had been affirmed by Berthollet and Proust. This conclusion has been confirmed by Klappow, who found the green sand of Peru composed of

7.3 per cent of copper
10.1 mucric acid
16.9 water.

100.0
MURRIN, or GARGLE, a contagious disease among cattle, principally caused by a hot dry season, or rather by a general perturbation of the air, which beget inflammation of the blood, and a swelling in the throat, that soon proves mortal, and is communicated from one to another, though it generally does not farther than to those of the same kind.

The symptoms of this disease are, a hanging down and swelling of the head, abundance of gum in the eyes, rattling in the throat, a short breath, palpitation of the heart, a lingering, a hot breath, and a shining tongue.

MURRAYA, a genus of the class and order decidua Montgomery. The calyx is five-parted; corolla bell-shaped, with a nec- tum encircling the germ; berry one-seeded. There is one species, a tree of the East Indies.

MUS, the rat, a genus of quadrupeds of the order glires. The generic character is, upper-front-teeth wedge-shaped; grinders on each side three, sometimes only two; clavicles or collar-bones in the skeleton.

This numerous tribe constitutes a formid-able phalanx against which man is not unacquainted.

1. Muriatic acid is an invisible elastic fluid, resembling common air in its mechanical properties. Its specific gravity, according to the experiments of Mr. Kirwan, is 0.00315, or nearly double that of common air. It is not in contact with common air, it forms with it a visible white smoke. If a bottle of it is drawn into the mouth, it is found to be excessively acid; much more so than vinegar.

2. Animals are incapable of breathing it, and when plunged into jars filled with it, they die instantaneously in convulsions. Neither will any combustible burn in it. It is remarkable, however, that a considerable effect upon the flame of combustible bodies; for if a burning taper is plunged into it, the flame, just before it goes out, may be observed to assume a green colour, and the moment that appears next time the taper is lighted.

3. A little water is let up into a jar filled with this gas, the whole gas disappears in an instant, the mercury ascends, fills the jar, and pushes the water to the very top. The reason of this is, that there exists a strong affinity between muriatic acid gas and water; and, whenever they come in contact, they combine and form a liquid, or, which is the same thing, the water absorbs the gas. Hence the necessity of making experiments with this gas over mercury.

4. In the water cistern not a particle of gas would be procured. Nay, the water of the trough would rush to the retort and fill it completely. It is this affinity between the gaseous gas and water which occasions the white smoke that appears when the gas is mixed with common air. It absorbs the vapour of water which always exists in common air. The solution of muriatic acid gas in such uncertainly denominated simply muriatic acid by chemists.

5. Muriatic acid gas is capable of combining with oxygen. To obtain the combination, we have only to put a quantity of the black oxide of manganese in powder into a retort, and pour over it liquid muriatic acid. Heat is then to be applied to the mixture, and the acid of the retort plunged under water. An effervescence takes place, and a green-coloured gas comes out at the bottom of the retort, which may be received in the usual manner in jars. This gas has been ascertained to be a compound of muriatic acid and oxygen. It is called muriatic acid, and will come under our consideration hereafter.

6. It does not appear from any experiments that have been hitherto made, that any of the simple combustibles are capable of combining with muriatic acid gas. Dr. Priestley found, that sulphur absorbed slowly about the fifth part of it. What remained was inflammable air, burning with a blue flame, and not absorbed by water. He found, however, that phosphorus smoke absorbed a sensible quantity of it, and that charcoal absorbed it very fast. Hydrogen gas does not produce any sensible change in it. Neither does it seem capable of being affected by azotic gases.

Muriatic acid is capable of combining with two doses of oxygen only. With the first dose, it forms oxymuriatic acid; with the second, hyperoxymuriatic acid. The first of these, fumes of it, is called hydrochloric gas, to be termed an oxide rather than an acid.

MURIATS. The muriats are a genus of salts which have been long known, and from which indeed the whole of the class have borrowed their name; for to them belongs com- mon salt, the most important and the most indispensably necessary of all the salts. They may be distinguished by the following properties:

When heated, they melt, and are volatil- ized, at least in part, without undergoing de-composition. Of these parts, the portions which fly off contain an excess of acid.

Not in the least altered by combustibles, even when assisted by heat. Soluble in water. For the most part they raise the boiling-point of water.

Effervesce with sulphuric acid, and white acid fumes of muriatic acid are disengaged. When mixed with nitric acid, they exhale the odour of oxymuriatic acid.
1. Mus zibethicus, musk rat. In the Memoirs of the French Academy of Sciences for the year 1725, there is a complete and excellent description of this animal by Mons. Sarrazin, at that time king’s physician at Quebec. From the above description it appears that the count de Buffon has drawn upon the major part of his own account, and indeed it does not appear possible to add any new material to what Mons. Sarrazin has delivered. This animal is of the size of a small rabbit, and is extremely common in Canada. Its head is short, like that of a water-rat; the eyes large; the ears very short, rounded, and covered externally as well as internally with hair. It has, like the rest of this tribe, four very strong cutting teeth, of which those in the lower jaw are near an inch long; those in the upper somewhat shorter: the fur on the whole body is soft and glossy, and beneath is a fine fur, or thick down, as in the beaver; the toes on all the feet are simple, or without membranes, and are covered with hair; the tail is nearly as long as the body, and is of the same form with that of the sorenus muschatus, being laterally compressed; it is nearly naked, into which are inclosed with small scales intermixed with scattered hairs. The general colour of the animal is a reddish brown; of the tail ash-colour. In its general appearance, this animal so greatly resembles the beaver, except in size, and in the form of its tail. It has also similar instincts and dispositions; living in a social state in the winter, in curiously-constructed huts or cabins, built mostly of sticks, and covered with mud or lake or river. These huts are about two feet in height, and nearly three feet in diameter, plastered with great neatness on the inside, and covered externally with a kind of basket-work, of rushes, &c. interlaced together, so as to form a compact and secure guard, impervious by water. During the winter these receptacles are generally covered by several feet of snow, and the animals reside in them without being incommoded by it; several families commonly inhabiting each cabin. It is added that the outer shells of these receptacles are furnished with a series of steps, to prevent them from being injured by inundations. These animals do not lay up a store of grain like the beaver, but form subterraneous passages beneath the ground, round their cabins, to give themselves an opportunity of procuring occasional supplies of roots, herbage, &c. According to Mons. Sarrazin, the animal is particularly calculated by nature for its subterraneous habits, having a great muscular force in its skin, which enables it to contract its body occasionally into a small volume; it has also a great supple- ness in the false ribs, which easily admit of contraction, so that it is enabled to pass through holes impervious to much smaller animals than itself. During the summer these creatures wander about in pairs, feeding voraciously on herbs and roots. Their odour, which resembles that of musk, is so strong as to be perceived at a considerable distance; and the skin, when taken from the body, still retains the peculiar odour. This odour is owing to a whitish fluid deposited in certain globules situated near the origin of the tail. It has been supposed that the calamus aromaticus, or sweet flag (acorus calamus, Lin.), which these animals select as a favourite food, may contribute to their fragrant smell. They walk and run in an awkward manner, like the beaver, and their movements are so readily as that animal, their feet being furnished with webs. Their voice is said to resemble a groan. The females produce their young towards the beginning of summer, and have five or six at a birth; they are also, if taken early, are easily tamed, and become very active and playful; and it is remarkable that the tail, which in the full-grown animal is as long as the body, is at that period very short.

The fur of this species is greatly esteemed as a commercial article, resembling that of the beaver. Linnaeus, in the twelfth edition of the Systema Naturae, ranked the animal under the genus castor; and Mr. Pennant has followed his example. Mr. Schreber, however, considers it as belonging to the proper genus. See Plate Nat. Hist. fig. 279.

2. Mus decumanus, Norway rat. This domestic species, which is now become the common rat of our own island, and is popularly known by the name of the Norway rat, is supposed to be a native of India and Persia, from which countries it has been imported into England; it seems to have made a natural conquest over the black rat, which is now become rare in comparison. The brown rat is larger than the black rat, measuring nine inches from the nose to the tail, which is of the same length, and marked on the back into about 200 rings or circular spaces; the colour of the animal is a pale tawny-grey, whitish beneath; the feet have four toes, with a claw in place of a fifth. It is a bold animal, and possesses great havoc in granaries, &c. Sometimes it takes up its residence in the banks of waters, and swims occasionally with almost as much facility as the water rat, or mus amphibius. In its general manner of life it appears to agree with the black rat; and not only devours grain and fruits, but preys on poultry, rabbits, and various other animals. It is a very prolific species, and produces from ten to twelve or fourteen, of a size and shape similar to the brown rat, in the course of a single year. When closely pursued, it will sometimes turn upon its adversary, and bite with great severity. It seems to have made its first appearance in England about seventy years ago, and is still much less frequent in France and some other parts of the Continent than the black rat.

3. Mus ratus, black rat. This species, like the former, though now so common in most parts of Europe, is supposed to have been originally introduced from India and Persia. Its general length from nose to tail is seven inches, and of the tail eight inches; the colour of the head and whole upper part of the body is a dark blackish grey; the belly is of a dull ash-colour; the legs are dusky, and very slightly covered with hair; the fore feet, as in the brown rat, have only four toes, with a small claw in place of a fifth; the tail is nearly naked, coated with a scaly skin, and marked into numerous divisions or rings. Like the former species, this animal breeds freely, and commonly breeds about six or seven young at a time. Sometimes they are enabled to overstock the place of their abode, in which case they fight and devour each other. It is said that this is the reason why these animals, after being extremely troublesome, sometimes disappear suddenly. Various are the methods made use of for the expulsion of rats from the places they frequent; among which none is more regular than to employ a skilful animal, who tells us he had been informed that if a rat is caught and a bell tied round its neck, and then set at liberty, it will drive away the rest wherever it goes. This expedient appears to be occasionally practised in modern times with success. A gentleman travelling through Mecklenburgh, about 30 years ago, was witness to the following curious circumstance in the post-house in New Curzon. After dinner, the landlord placed on the floor a large dish of soup, and gave a loud whistle. Immediately there came into the room a manitou, a fine Angora cat, an old raven, and a remarkably large rat, with a bell about its neck. The four animals went to the cat, and without disturbing each other, fed together; after which the dog, cat, and rat, lay before the fire, while the raven hopped about the room.

The landlord, after accounting for the familiarity which existed among the animals, informed his guest that the rat was the most useful of the four, for the noise he made had completely freed the house from the rats and mice with which it was before infested.

4. Mus musculus, common mouse. The mouse and aperea are so universally known, that it seems almost unnecessary to particularise it by a formal description. It is a general inhabitant of almost every part of the Old Continent, but is doubtless originally a native of America, though now so abundantly common in many parts of the New World, as well as in many of its scattered islands. The mouse, though wild and extremely timid, is not of a ferocious disposition, but may be easily tamed, and so after it has been taken, will begin to feed without fear, in the immediate presence of its captors. The white variety is frequently kept in a tame state, and receives an additional beauty from the bright red colour of its eyes; a particularity which generally accompanies the white varieties, not only of this tribe, but of many other quadrupeds.

The mouse is a prolific animal: the experiment of Aristotle is well known, and often repeated. A pregnant mouse in a vessel of grain, and after having been found in it no less than the number of 120, all of which, he concluded, were the descendants of the mouse he had inclosed.

The fur of the mouse is remarkably soft and elegant, and the structure of the hair in this animal, as well as in the rat, and probably in many others of this genus, is singularly curious; each hair, when microscopically examined, appearing internally divided into a kind of transverse partitions, as if by the continuation of a spiral structure; a structure very different from that of the hair of most other animals, and of which the particular nature seems not very distinctly understood.

Dorchain, in his Physio-theology, conceives that this mode of formation of spiral fibre may serve for the "gentle evacuation of some humour out of the body;" and adds, that this perhaps the hair serves as well for the conveyance of the blood of hairy animals as to fence against cold and wet. Whatever it be, is the real nature or use of the above structure, its appearance cannot fail to excite astonishment in those who take the pains of examining
...ing it with a good microscope, by which they will obtain a clear idea of this curious appearance.

In Aldrovandus, who relates the circumstance from Gesner, we meet with a direction for changing as it were, a mouse into a cat, by making it the incessant persecutor and enemy of the rest of its species. This is to be effected by placing several mice together in a vessel without food, when, after a certain time, they will be so stimulated by hunger as to destroy each other: the surviving animal being then liberated, will, according to this author, become the most destructive enemy of his own tribe, and will kill every one he meets. Another singular and most cruel experiment is quoted by Aldrovandus from Mizzadas, who tells us, that if two or three mice are shut up in an earthen pot, and placed over a fire, the shrill cries which they utter will attract the mice in the other parts of the house, and cause them to precipitate themselves into the fire. Whatever there may be in this experiment, it is certain that, on the shrill cry of distress uttered by one of these animals kept with several others in a cage, the rest will frequently utter the same cries.

5. Mus Sylvaticus, wood mouse. This animal chiefly frequents dry and elevated grounds, and is found in woods and fields in great plenty. It appears to be common in all the temperate parts of Europe, and even in Russia. It sometimes varies in size, individuals being occasionally met with which exceed the rest in magnitude, though differing in no other respect. Its general length is about four and a half feet from the tail, and the tail, which is slightly covered with hair, measures four inches. The colour of the animal is a yellowish brown above and whitish beneath; the colours being pretty distinctly marked or separated; the eyes are full and black, and the snout rather blunt. These animals retire into holes among bushes, wood, and under the trunks of trees, where they amass great quantities of acorns, nuts, and herbage. When the wheat is sown, a whole bushel has sometimes been found in a single hole. These holes are about a foot or more under ground, and are often divided into two apartments; the one for living in alone with a provision, and the other for the management of provisions. Considerable damage is often done to plantations by these animals, which carry off new-sown acorns, &c. The count de Buffon affirms, that in France more mischief is done by these creatures than by all the birds and other animals put together; and adds, that the only way to prevent this is by laying traps, at ten paces amongst the general extent of the sown ground. No other apparatus, he says, is necessary than a roasted walnut, placed under a stone supported by a stick; the animals come to eat the walnut, which they prefer to acorns; and as the walnut is fixed to the stick, whenever they touch it, the stone falls and kills them. The same expedient may be as successfully used for the destruction of the short-tailed field mouse, which likewise commits great havoc in fields and meadows. The first person who first practised this experiment, he desired that all the field mice thus taken in traps might be brought to him, and found with astonishment, that above 100 were taken each day from a piece of ground consisting only of about 40 of our acres. From the 13th of October, 1769, above 9000 were destroyed in this manner. When the frost becomes severe, they retire into their holes, and feed on the stores they have collected. They abound, like many other small animals, in summer, and are far less common in the spring. For it is possible they fall ill in the winter, it is thought that they destroy each other: a circumstance which is known occasionally to occur in mice, in places frequented by species of these animals.

The long-tailed field mouse is a very prolific animal, breeding more than once a year, and often producing litters of ten at a time. In one of their holes have been found two females, with 20 young. Specimens have sometimes been seen perfectly white, with red eyes.

6. Mus musculus, harvest mouse. This small species seems to have escaped the notice of British naturalists till it was observed by the late Mr. Gilbert White, of Selborne in Hampshire, in which county it is frequent. Mr. White, in the year 1767, communicated the animal to Mr. Pennant, who introduced it into the British Zoology.

"These mice," says Mr. White, "are much smaller and more slender than the mus domesticus medius of Ray, and have none of the squirrel or dormouse colour; their belly is white; a straight line along their sides divides the shades of their back and belly. They never enter into houses, are carried in racks and barns with the sheaves, and are abundant in harvest, and build their nest amidst the straw of corn above ground, and sometimes in thistles. They breed as many as eight at a litter, in a little round nest composed of the blades of grass or wheat. One of these nests was procured in the autumn of 1767, most artificially platted, and composed of the blades of wheat, perfectly round, and about the size of a cricket-ball, with the aperture at one side, in which there was not a discovery to what part it belonged. It was so compact and well filled, that it would roll across the table without being decomposed, though it contained eight little mice that were dead and blind; and when this nest was perfectly full, how could the dam come at her litter respectively, so as to administer a teat to each? Perhaps she opens different places for that purpose, adjusting them again when the business is over; but she could not possibly be contained herself in the hall with her young, which moreover would be daily increasing in bulk. This wonderful precauent cradle, an elegant instance of the effect of instinct, was found in a wheat-field, suspended in the head of a thistle.

Mr. White adds, that "though these animals hang their nests for breeding up amidst the straws of standing corn, above ground, yet in the winter they burrow deep in the earth, and make warm beds of grass; but their grand rendezvous seems to be in corn-ricks, into which they are carried in harvest." A neighbour of Mr. White's housed an oat-rick, in which were some hundred and eighty mice concealed under the thatch. The measure of the animal is just two inches and a quarter from nose to tail, and the tail is just two inches long. 'Two of them in a scale just weighed down a copper halfpenny, which was out the third of an ounce avoidipos'; so that they may be considered as the smallest of the British quadrupeds.

7. Mus minutus, house mouse. This species, according to Dr. Pallas, is frequent in the birch-woods of Siberia, as well as in many of the temperate parts of Russia, frequenting corn-fields and barns. Its general colour is a deep fawn above and white below; the nose is sharpish and of a dusky color, with a whiteness at the corners of the mouth; the ears are laid in the fur; the feet grey; the length from nose to tail is little more than two inches, and the weight about half a dram. Those found in Siberia are of a richer or more fulvous colour than those of other regions. This animal, Dr. Pallas says, is very frequent in autumn and winter in barns and about granaries, and is often found intermixed with the mus agrarius, inhabiting similar places. It seems extremely nearly allied to the harvest mouse, and it is not impossible that it may in reality be the same animal, the other species appearing almost too slight for a specific distinction.

8. Mus ambulatorius, water rat. The water rat is a general inhabitant of the temperate, and even the colder, parts of Europe and Asia, and occurs also in North America, frequenting rivers and stagnant waters, and forming its burrows in the banks. It is of a thicker and shorter form than many others of this genus, and has somewhat of the shape of a beetle. Mr. Ray, a beaver of the country of Wiltshire, describes it as having the fore-feet webbed; and Linnaeus, in his Systema Naturae, characterizes it from that very circumstance, but acknowledges that he had not himself examined the animal. In reality, however, there is no such appearance in the feet of the water rat, and the notion seems to have been hastily adopted from observing the small fish with which it swims and dives. The general length of the water rat is about seven inches, and the tail about five. Its colour is blackish-ferruginous above, and deep cinereous beneath; the nose is thick and blunt, and nearly as long as the eye. The ears rounded and held in the fur. In colour it appears to be a different species, being sometimes nearly black, and sometimes paler than usual. It also varies as to size, and the varieties have been considered as distinct species. This animal never frequents houses, but confines itself to the banks of waters, and is supposed to live on fish, frogs, &c. and probably on various roots and other vegetable substances. Dr. Pallas, however, is unwilling to admit that it preys at all upon fish, though reported so to do by the count de Buffon and others. At some seasons of the year it is observed to have a musky scent. The female produces her young, which are born in April, and generally brings about five or six at a time. The measure of this species, as given by Mr. Schreber, are as follow, viz. from nose to tail six inches and a half, and of the tail three inches.

9. Mus Lemmus, lemming rat. The wonderful migrations of these species have long rendered it celebrated in the annals of natural history. It is remarkable, however, that no accurate figure of it was published till Dr. Pallas caused it to be engraved in his excellent work on the Gites. The first description of the lemming seems to have been Olaus Magnus, from whom...
several of the other naturalists have copied their accounts. Afterwards Woransus gave a  
more particular description; and, indeed, as Leach, in his Natural History of  
Transquana, in the Acts Holmienesis, and Dr. Pallas, in his publication before  
mentioned, have still further elucidated its history and manners. See Plate Nat. Hist. fig. 280.

The lemming differs in size and colour according to the regions it inhabits: those  
which are found in Norway being almost as large as a water rat, while those of Lapland and Siberia are scarce larger than a field mouse; the Norwegian inhabiting more than five inches from nose to tail, while those of Lapland and Siberia scarce exceed three.

The colour of the Norwegian kind is an elegant variegation of black and tawny on the upper parts, disposed in patches and clouded markings; the sides of the head and the under parts of the body being white, the legs and tail greyish. In the Lapland kind the colour is chiefly a tawny brown above, with some indistinct dusky variegations, and the cheeks and ears of a dull white; the claws are also smaller than in the Norwegian animal. The head of the lemming is large, short, thick, and well furred: the snout very obtuse; the ears very small, set in the fur; the eyes small; the neck short and broad; the body thick; and the limbs short and stout, especially the fore legs; the fore-feet are broad, furnished with five toes, which have strong, crooked claws, and the hind feet, to which belong two dull white claws, of which the middle three are longer than the rest; on the hind-feet are also five toes, with smaller claws than those of the fore-feet; the tail is very short, thick, cylindrical, obtuse, and covered with strong hairs, disposed like those of a pencil at the tip.

The natural or general residence of the lemming is in the Alpine or mountainous parts of Lapland and Norway, from which tracts, at particular but uncertain periods, it descends into the plains below in immense troops, and by its incredible numbers becomes a temporary scourge to the country, devouring the grain and herbage, and causing great loss, equal to those caused by an army of locusts. These migrations of the lemming seldom happen oftener than once in ten years, and in some districts still less frequently. They are supposed to arise from an unusual multiplication of the animals in the mountainous parts they inhabit, together with a defect of food; and, perhaps, a kind of instinctive prescience of untoward seasons, for it has been observed that their migrations are made in the autumn of such years as are followed by a very severe winter. The inclination or instinctive faculty which induces them, with one consent, to assemble from a wide region, elect themselves into an army, and descend from the mountains into the neighbouring plains, in the form of a firm phalanx, moving on in a straight line, resolutely surmounting every obstacle, and undismayed by every danger, cannot be contemplated without astonishment. All who have written on the subject agree that they proceed in a direct course, so that the ground along which they have passed appears at a distance as if it had been ploughed; their tails deviated to the very roots, in numerous stripes, or parallel paths, of one or two spans broad, and at the distance of some ells from each other. This army of mice moves hastily by night, or early in the morning, devouring the herbage as they pass, in such a manner that the surface appears as if beaten smooth; and hence it happens in their way have any effect in altering their route; neither fires, nor deep ravines, nor torrents, nor marshes or lakes; they proceed obstinately in a straight line; and if they meet with meadows or marshes, or even perish in the waters, and are found dead by the shores. If a rick of hay or corn occurs in their passage, they eat through it; but if rocks intervene which they cannot pass, they go around, and then resume their former straight direction. If disturbed or pursued while swimming over a lake, and their phalanx separated by oars or poles, they will not recede, but keep swimming directly on, and soon get into regular order again; and have even been sometimes known to endeavour to board or pass over a vessel. On their passage over land, if attacked by men, they will raise themselves up, uttering a kind of barking sound, and, with their fore-feet, or by ramming their heads, and will fasten so fiercely at the end of a stick, as to suffer themselves to be swung about before they will quit their hold; and are with great difficulty put to flight. It is said that sometimes whole regiments have placed in these armies during their migrations, and that the animals thus destroy each other.

In their general manner of life they are not observed to be of a social disposition, but to reside in a kind of scattered manner, in holes beneath the surface, without laying up any regular provision, like some other animals of this tribe. They are supposed to have bred several times in the year, and to a number of five or six at once. It has been observed that the females have sometimes brought forth during their migrations, and have been carrying their young in their mouths, and others on their backs. They are found on the plains of Lapland they are eaten, and are said to resemble squirrels in taste.

It was once believed that these animals fell from the clouds at particular seasons, and some have affirmed that they have seen a lemming in its descent; but an accident of this kind is easily accounted for, on the supposition of a lemming escaping now and then from the claws of some bird which had seized it, and thus falling to the ground; a circumstance which is not very unlikely to take place when the animals are seized by crows, gulls, &c.

10. Mus economicus, economic rat. The economic rat, so named from its provident disposition, and the skill with which it collects its provisions, is a native of Siberia, inhabiting that country in vast abundance, and even extending as far as Kamtschatka. Its curious history has been given with great exactness by Dr. Pallas; he informs us that these little animals construct their burrows with wonderful skill, immediately below the surface, in soft turfy soils; forming a chamber, of a flatish arched form, of a small height, and about a foot in diameter, to which they sometimes add as many as thirty small pipes or entrances, and in them they frequent other caverns, in which they deposit their winter stores; these are said to consist of various kinds of plants, even of some species which are poisonous to man and kind. They gather together in the summer, forage, and live like herds; but when the time arrives, and they sometimes bring them out of their cells in order to give them a more thorough drying in the sun. The chief labour rests on the females; the males during the summer wandering about in a solitary state, inhabiting some old nests occasionally, and living during that period on berries, without touching the hoards, which are reserved for winter, when the male and female reside together in the same nest. They are said to breed several times in the year, the female producing two or three young at a time.

The migrations of this little species are not less extraordinary than those of the lemming, and take place at uncertain periods. Dr. Pallas imagines that the migrations of those inhabitants of Kamtschatka, so frequently observed, arise from some sensations of internal fire in that volcanic country, or from a prescience of some unusual and bad season. Whatever is the cause, the fact is certain. At such periods they gather together, during the season, in surprising numbers, except the few that reside about villages, where they can pick up some subsistence; and this makes it probable that their migrations, like those of the lemming, are rather owing to want of food. The mighty host proceeds in a direct course westward, occasionally swimming with the utmost intrepidity over rivers, lakes, and even arms of the sea. During these perilous adventures, some are drowned, and others destroyed by water-fowl, fish, &c.; those which escape rest a while to bask, dry their fur, and refresh themselves, and then again set out on their migration. It is said that the miners have often seen them in the mines, where they happen to find them in this fatigued situation, treat them with the utmost tenderness, and endeavour by every possible method to refresh and restore them to life and vigour, for the smaller animals are so much esteemed by the Kamtschakians as these, since to their labours they owe many a delicious repast, robbing their hearths in autumn, and leaving there some kind of provision in return, accompanied by some rude but curious presents of way of amends for the theft. As soon as the migrating host of these animals has crossed the river Peschenik, at the head of the gulf of that name, it turns southward, and reaches the rivers Yenisei and Ochot about the middle of July; the space thus traversed appears astonishing, on consulting the map of the country. The flocks during this time are so numerous that it is said to be impossible to see them all pass. Their return into Kamtschatka is in October, and is attended with the utmost festivity and welcome on the part of the natives, who consider their arrival as a sure sign of a good summer and a good season of fishing, and they are said equally to lament their migrations, which are usually succeeded by rainy and tempestuous weather.

This curious species is generally of a tawny colour, darker on the back, and lighter on
more approaching to an ash-coloured whiteness beneath; its usual length is about four inches and an eighth; its body proportions are distinctly human, its limbs are strong; its eyes small, its ears naked, very short and round, and almost hid beneath the fur of the head.

This animal is also supposed to be an inhabitant of Iceland; at least a species which must be necessarily allied to it is found in that country, and is said to be particularly plentiful in the wood of Hussels. In that country, where berries are but thinly dispersed, the little animals are obliged to cross rivers to make their way to the berry-laden excursions, and in their return are obliged to retrace the stream; their manner of performing which is thus related by Mr. Olafsen, from the accounts of others, communicated to himself:

"The party, consisting of from six to ten, select a flat piece of dried cow-dung, on which they place the berries they have collected in a heap, on the middle; and then, by their united force, drawing it to the water's edge, launch it, and embark, placing themselves round it with their feet, and their tails between them; and thus, by the students of the water's current, and their tails pendant in the stream, and serving the purpose of rudders."

11. Mus socialis, social mouse. The social mouse is a native of the Caspian deserts between the Volga and the Yark, and the province of Khiva. It lives in low sandy situations, in large societies; the ground in many places being covered with the little hillocks formed by the earth cast out in forming the burrows, which, when dry, is said to be about a span deep, with eight or more passages. The animals are always observed to live in pairs, or with a family; they are fond of tulip-roots, which form a principal article of their food. They appear chiefly in the spring, when they are very numerous, but are rarely seen in autumn, and are supposed either to migrate in autumn or to conceal themselves among the bushes, &c. in the winter to shelter themselves in burrows. The body of the species is thick, and the nose blunt; the whiskers white; the ears oval and naked; the limbs short and strong, and the tail slender. The upper parts are of a light grey, and the under white.

12. Mus cricetus, hamster. Of the pouched rats, and the hamster is the most remarkable, and indeed is the only European species provided with those peculiar receptacles, which are situated on each side the mouth, and when empty are so far contractile as not to appear externally, but when filled resemble a pair of tumid bladders, having a smooth veinous surface, concealed, however, under the fur or skin of the cheeks, which bulge out extremely in this state. They are so large as to hold the quantity of a quarter of a pint, English measure.

The general size of the hamster is nearly that of a brown or Norway rat, but it is of a much thicker form, and has a short tail. Its colour is a rich reddish brown above, and black beneath. The muzzle is whitish, the cheeks reddish, and on each side the body are three moderately large oval white spots, of which those on the shoulders are the largest; the ears are moderately large and rounded, and the tail almost bare, and about three inches long; on the fore-feet are four toes, with a claw in place of a fifth, and on the hind-feet are five toes. Sometimes the hamster varies in colour, being found either black with a white muzzle and a pale yellowish white. The male is always much larger than the female. On each side the lower part of the back is an almost bare spot, covered only with very short down.

The hamster inhabits Siberia and the south of Russia. It is also found in Poland, as well as in many parts of Germany. They are very destructive in some districts, devouring great quantities of grain, which they carry off in their cheek-pouches, and deposit in their burrows, in order to devour during the autumn. Their habitations, which they dig to the depth of three or four feet, consist of more or fewer apartments, according to the age of the animal; a young hamster makes them hardly a foot deep; an old one sinks them to the depth of four or five feet, and the whole diameter of the residence, taking in all its habitations, is sometimes eight or ten feet. The principal chamber is lined with dried grass, food, and urine; the rest are destined for the preservation of provisions, or which he amasses a great quantity during the autumn. Each hole has two apertures; the one descending obliquely, and the other in a perpendicular line; through this latter that the animal goes in and out. The holes of the females, who never reside with the males, are somewhat different in their arrangement, and have more numerous passages. The females breed once or twice a year, producing five or six, and sometimes as many as sixteen or eighteen. The growth of the young is rapid, and they are soon able to provide for themselves.

The hamster feeds on all kinds of herbs and roots, as well as on grain, and even occasionally on the smaller animals. "In harvest-time (says Mr. Allamand) he makes his excursions for provision, and carries every article he can find into his granary. To facilitate the transportation of his food, nature has provided him with two pouches in the inside of each cheek. On the outside these pouches are membranous, smooth, and shining; and in the inside are a great many glands, which continue rolled up, with all its limbs infllexible, its body perfectly cold, and without the least appearance of life. In this state it may even be opened; when the heart is seen alternately contracting and dilating, but with a motion so slow as to escape observation; not exceeding 15 pulsations in a minute, though in the waking state of the animal it beats 150 pulsations in the same time. It is added that the fat of the creature has the appearance of being pure, and that its intestines do not exhibit the smallest symptoms of irritability on the application of the strongest stimulants, and the electric shock may be passed through it without effect. This lethargy of the hamster has been generally attributed to lack of cold alone; but late observations have proved, that unless at one certain depth beneath the surface, so as to be beyond the access of the external air, the animal does not fall into its state of torpidity, and that the exposure on the surface does not affect it. On the contrary, while dug up out of its burrow, and exposed to the air, it infallibly awakes in a few hours. The waking of the hamster is a gradual operation; he first loses the rigidity of his limbs; then makes provisions for the winter; and occasionally, after this he begins to move his limbs, opens his mouth, and utters a sort of unpleasant rattling sound. After continuing these operations for some time, he at length opes his eyes, and in a short time, about for some time, as if in a state of intoxication, till at length, after resting a small space, he perfectly recovers his usual powers. This transition from torpidity to activity requires more or less of time, according to the temperature of the air, and other circumstances. When exposed to a cold air, he is sometimes two hours in waking; but in a warmer air the change is effected in half the time.

The manners of the hamster are generally represented as far from pleasing. No society appears to exist among these animals. They are naturally very fierce, and make a desperate defence when attacked; they also pursue and destroy every animal which they are capable of conquering, not excepting even the weaker individuals of their own species. They are said to be provided with a large number of the seeds of licorice, and to abound in the districts where that plant is cultivated. According to Mr. Sultzer, they abound to such a degree in Gotta, that in one year 11,564, and in another 8,089 of their skins were delivered in the Hotel de Ville of that capital, where the hamster is proscribed on account of the devastations it commits among the corn.

The common or Canadian rat. - This, which is a species but lately discovered, seems to be the most remarkable of all the pouched rats for the proportional size of the receptacles. It is a native of Canada, and of a much larger size than the common rat, and is of a pale greyish-brown colour, rather lighter beneath; the length to the tail is about nine inches, and that of the tail, which is but slightly covered with hair, is about twenty inches; the ears are short; the forefeet strong, and well adapted for burrowing in the ground, having five claws, of which the three middle ones are very large and long; the interior one much smaller, and the exterior very small, with a large, long, and curved claw. A more faithful representation
is given in Dr. Shaw's excellent work, which is accompanied by an outline of the head, in its natural size, in order to show the teeth and cheek-pouches. The manners of this species are at present unknown; but it may be concluded that it lays in a stock of provisions, either for autumnal or winter food. The pouches of the individual specimen described, when first brought to government Procotol, were filled with a kind of earthly substance; it is, therefore, not improbable that the Indians who caught the animal must have inclosed it thus, in order to preserve it in its utmost extent.

14. Mus typhlus, blind rat. This is perhaps one of the largest and most remarkable of its tribe, measuring between seven and eight inches in length, and being entirely destitute both of eyes and tail; the defect of the former is a very singular circumstance, and the animal perhaps affords the only instance of a truly blind or eyeless quadruped. In the mole, the eyes, however small and deeply seated, are yet perfect in their kind, and are calculated for acute vision; still enable the animal to avoid the danger of exposure; but in the quadruped now under consideration, there are merely a pair of subcutaneous folds of eyes, smaller than poppy-seeds, and of which the animal is probably, however, that even these minute organs are sufficient to give an obscure perception of light, and to enable the animal to consult its safety by generally continuing beneath the surface. The external ears are also wanting, and the formima leading to the internal organs are very small, entirely hid by the fur, and situated at a great distance backward. There is scarce any distinction between the head and neck, and the whole form of the animal, like that of the mole, is calculated for a subterraneous life: the body being cylindric, the limbs very short, and the feet small and weak in comparison with those of moles, yet calculated for digging or burrowing in the ground. The colour of the animal is a greyish brown; the fur, which is very thick, soft, and downy, being composed of long durable roots, and greyish toward the tips; the head is lighter, and the abdomen darker than the other parts; the lower lip is also whitish, and sometimes a white mark extends along the forehead; the front teeth are large, and are not much bare or exserted; the lower pair being much longer than the upper. This singular species is a native of the southern parts of Russia, where it burrows to a great extent beneath the surface, forming several lateral passages, by which it may pass in quest of roots, &c. It is said to feed in particular on the roots of the cheruphyllum bulbosum. In the morning hours it sometimes quits its hold to bask in the sunshine, and if disturbed takes refuge beneath the surface; burrowing with great agility, and frequently in a perpendicular direction. Its bite is very severe when attacked. It has no voice, but emits a kind of roaring sound, and generally, when it becomes alarmed, shows its teeth in a menacing manner, raising its head at the same time. The female is said to produce from two to four young.

15. Mus Capensis, Cape rat. In its general shape, this animal is not unlike the great sand rat first described, and is equally common about the Cape of Good Hope; but it is far inferior in size, measuring about seven inches to the tail, which is very short, nearly white, and flattened; and, though this species is a dusky rosy ash-brown, paler or more inclining to whithen beneath; the end or tip of the nose is naked and black, the remaining white, and on each side of the cheeks, and on the lower sides of the cheeks, and spaces round the eyes, are also white, and on the hind part of the head is an oval white spot; the teeth are naturally exserted or naked, and are similar in shape to the great sand rat. In its manners and way of life, the animal is also similar to that species; and is very destructive to gardens, gnawing up hillocks, and eating various kinds of roots.

MUSA, the plantain tree, a genus of the monoeia order, in the polyandria class of plants, and in the natural method ranking under the 8th order, sclamisium. The calyx of the male hermaphrodite is a spathe or sheath; the corolla is dipetalous; the one petal erect and quinquedentate; the other, petal, a Nigeria doughnut. The female organs are six species, five of which are perfect; one style; the germen inferior and abortive. The female hermaphrodite has the calyx, corolla, filaments, and pistil, of the male hermaphrodite, with only one filament perfect; the berry is oblong, and three-angled below. There are three species:

1. Musa paradisiaca, is cultivated in all the islands of the West Indies, where the fruit serves the Indians for bread; and some of the white people also prefer it to most other things, especially the raise and cassava, or Indian bread. The plant rises with a short stalk 15 or 20 feet high; the lower part of the stalk is often as large as a man's thigh, diminishing gradually to the top, where the leaves come out on every side; these are often eight feet long, and from two to three broad, with a strong along midrib, and a great number of transverse veins running from the midrib to the borders of the leaf, which are thin and tender, so that wherever they are exposed to the open air, they are generally torn by the wind; for as they are large, the wind has great power against them; these leaves come out from the centre of the stalk, and are rolled up in an early stage; but when they are advanced above the stalk, they expand and turn backward. As these leaves come up rolled in this manner, their advance upward is so quick, that their growth may be discovered by the naked eye; and if a fine line is drawn across the top of the leaf, in an hour the leaf will be near an inch above it. When the plant is grown to its full height, the spikes of flowers appear in the centre, which is often near four feet long. The flowers come out in bunches, those in the lower part of the stalk being the largest; the others diminish in their size upward. Each of these bunches is covered with fully a sheath of a fine purple colour, which drops off when the flowers open. The upper part of the spike is made up of male flowers, which are not succeeded by fruit, but fall off with their covers. The fruit or plantain is about a foot long, and an inch and a half or two inches diameter: it is not green, but ripe pale-yellow. The skin is tough; and within is a soft pulp of a delicious sweet flavour. The spikes of the fruit are often so large as to weigh upwards of 40lb. The fruit of this sort is generally cut off before it is ripe, and the heart is roasted in a clear fire for a few minutes, and frequently turned: it is then scraped, and served up as bread. Boiled plantains are not so palatable.

This tree is cultivated on a very extensive scale in Jamaica, without the fruit of which, Dr. Wright says, these scarce be habitable, as no species of provision could supply their place. Even flour or bread itself would be less agreeable, and less able to support the laborious negro, so as to enable him to do his business, or to keep in health. Plantains also fatten horses, cattle, swine, dogs, fowls, and other domestic animals. The leaves, being smooth and soft, are employed as dressings after blisters. The water from the soft trunk is astrinvent, and employed by some to check diarrhoea. Every other part of the tree is useful in different parts of rural economy. The leaves are used for napkins and tablecloths, and are food for hogs.

2. Musa sapientum, the banana tree. This species differs from the preceding in having its stalks marked with slanting stripes, and spots. The fruit is shorter, stronger, and rounder; the pulp is softer, and of a more delicious taste. It is never eaten green; but when ripe it is very agreeable, and is a food relied on by all ranks of people in the West Indies. Both these plants were carried to the West Indies from the Canary Islands, whither, it is believed, they had been brought from Gniunes, where they grow naturally. They are also cultivated in Egypt, and in most other hot countries, where they grow to perfection in about ten months from their first planting to the ripening of their fruit. When their stalks are cut down, several suckers come up from the roots, which in six or eight months produce fruit; so that by cutting down the stalks at different times, there is a constant succession of fruit. Europe some of these plants are raised by gentlemen who have hot-houses capacious enough for their reception, in many of which they have ripened their fruit very well; but as they grow more and more large, they require more room in the stoves than most people are willing to allow them. They are propagated by suckers, which come from the roots of those plants that have fruited; and many times the younger plants, when stunted in growth, also put out suckers. The fruit of this tree is four or five inches long, of the size and shape of a middling cucumber, and of a high, grateful flavour: the leaves are divided into two yards long, and four broad in the middle; they join to the top of the trunk of the tree, and often contain in their cavities a great quantity of water which runs out upon a small incision being made into the tree, at the bottom of which the plantains grow in great bunches, that weigh 12 lb. and upwards.

The body of the tree is so porous as not to merit the name of wood; the tree is only perennial by its roots, and dies down to the ground every year. When the nature of the West Indies (says Lacti) understand to take a voyage, they make provision of a paste of banana, which, in case of need, serves them for nourishment and drink: for
This purpose they take ripe bananas, and having squeezed them through a fine sieve, form the solid fruit into small leaves, which are dried in the sun or in hot ashes, after being previously wrapped up in the leaves of Indian flowering-reed.

Musca, fly, a genus of insects of the order Diptera. The generic character is: mouth formed into a fleshy proboscis, with two lateral lips; palp, none.

The vast extent of the genus musca makes it necessary to divide the whole into different subgroups, in order to the more readily investigation of the species. These divisions are instituted from the form of the antennae, which are either simple (without any lateral hair or plume), or serrated (that is, furnished with a lateral hair or plume). These divisions are further separated into others, according to the more or less downy or hairy appearance of the insects.

The first section of this genus comprehends such flies as have wings.

The larva, in the different tribes of flies, differ more in size, but in the complete insects, some being terrestrial, and others aquatic. Those of the more common kinds are commonly distinguished by the title of maggots, and spring from eggs deposited on various patriarchs and surfaces. Several of the aquatic kinds are of singularly curious formation, and exhibit wonderful examples of the provision ordained by nature for the preservation of even the smallest, and most seemingly contemptible of animals. Several are inhabitants of plants, feeding during this state on other living insects.

The general form of the chrysalis or pupa is that of an oval, differently modified, according to the species, and formed by the external skin of the larva, which hardens round the chrysalis. Some species, however, cast their skin before their change into the pupa state.

In this division one of the most remarkable species is the musca chamædon, which is a large black fly, with a broad flatish abdomen, having the sides of each segment yellow, forming so abrupt a transition across that part. It proceeds from an aquatic larva, of very considerable size, measuring two inches and a half in length, of a somewhat flattened shape, and of a brown colour, with a narrow or slender front, the body widening by degrees towards the middle, and from thence gradually tapering to the extremity or tail, which is terminated by a circle of radiating or diverging hairs. This larva is common in stagnant waters during the summer months, and passes into its chrysalis state without casting its skin, which dries over it, so as to preserve the former appearance of the animal in a more contracted state.

In this division also stands the musca vespæcola, a minute, fly-shaped fly, of a somewhat lengthened form, with a distinct resemblance to a tipupa. It is of a dull yellow colour, with transparent wings, the thorax marked above by a black ring, and below by ten black spots. The larva of this species measures above three quarters of an inch in length, and is of a pale yellowish-grey colour, slender and sharpened in front, and growing gradually broader towards the tail. It is found in the southern parts of Europe, and is not uncommon in some districts of France, and is remarkable for practising a method exactly similar to that of the hemerobius formicæcum in order to obtain its prey: excavating a circular cavity in the dry earth, and then, after a short distance from the verge of the cavity. This larva seems to have been first observed and described by Réamur, in the Memoirs of the French Academy for the year 1752. It assumes the state of a chrysalis by casting its skin, which rolls to the hinder part of the body: the chrysalis is of a dull reddish colour, and is rounded or clubbed at the upper part, suddenly tapering from thence to the extremity, and after lying nine or ten days, gives birth to the included insect.

Of the downy or slightly haired flies with bristled antennae, one of the most remarkable is the musca tropæa, which is about the size of a drone, and of a brown colour, with short wings, and a segment of the abdomen yellowish on each side. It proceeds from a larva of a very singular appearance, being a long-tailed brown maggot, of rather slow motion, measuring about three quarters of an inch in length, of the tail, which is extensive, and consists of a double tube, the exterior annulated into numerous segments, and the interior slender, and terminated by a circle of hairs, surrounding a spiracular orifice. This maggot is seen in muddy stagnant waters, drains, and other places of the dirtiest description; and notwithstanding its unpleasing appearance, exhibits, when accurately examined, many particulars very well worthy of admiration.

The feet in particular, which are seven in number on each side, are wonderfully calculated for enabling the animal to ascend walls or other perpendicular places, in apparently impossible situations in which it may undergo its change into chrysalis, being very broad, and beset on their under surface with numerous small hooked claws, giving it the power of clinging with security during its sluggish movements. Of this larva a particular notice is stated on the authority of Linneus, which, if true, may indeed well be numbered among the Miracula Insectorum (the title of the paper in the Annalenstes Academica, in which it is annexed), viz. being a frequent inhabitant of the turbid pulp used in the process of paper-making, it is often exposed to the action of the wooden mallets used in the process, as well as squeezed in the longest and sharpest press, and yet suffers unimpaired these seemingly destructive operations!!

The above larva commonly changes to a chrysalis about the end of August, the skin contracting and drying round the body, and the tail continuing in a shrivelled state. After thus remaining about the space of a fortnight, it gives birth to the complete insect, which has so much the general appearance of a drone, that it is very frequently mistaken for an insect. It is extremely common during the month of September.

Musca pendula, which belongs also to this division of the genus, is a moderately large and very beautiful insect. Its colour is black, with four bright yellow stripes down the thorax, and three broad interrupted bars across the abdomen; or, in other words, this fly might be described as of a bright yellow colour, with the thorax marked by four longitudinal black lines, and the abdomen by three transverse black stripes down the middle. Its larva, which is an inhabitant of stagnant waters, is of a still more remarkable appearance than that of the immediately preceding species, which it resembles in size, but is of a pale colour, and furnished with a tail of greater length, composed of a double tube, the interior of which is very slender, extended at the pleasure of the animal to a vast length, and terminated by a very small spiracle. The length of this tube is therefore varied according to the greater or smaller depth at which the insect chooses to continue, the tip reaching to the surface, in order to supply the requisite quantity of air. Sometimes great numbers of them are covered or twisted together by their tails in such a manner that it is by no means easy to separate any one from the rest. The chrysalis resembles that of the musca tropæa, the reason for the being visible in a dried and contracted state. The complete insect is frequently seen on flowers during the autumnal season.

Among the hairy or bristly flies with plumbed antennae stands the well-known species called musca carrionis, or the common large blow-fly. This, as every one knows, deposits its eggs on animal flesh, either fresh or putrid. The larva or maggots hatch about the space of a fortnight, and when full-grown, which happens in eight or ten days, are of a white or yellowish-white colour with a slight tinge of pale-red, and of a lengthened shape, with a sharpened front, in which the month is situated, and from whence the body gradually enlarges in size to the last or terminal segment, which is of a very broad and flattened form, surrounded by several slightly prominent lips, and furnished with a pair of dusky specks resembling eyes: so that an inaccurate spectator might easily mistake this part for the head, and the proper head for the tail. When the animal changes to a chrysalis, the skin dries round it, and the whole assumes a complete case and a reddish brown, soon changing into a reddish-brown. In ten days more the fly itself emerges, which is too well known to require particular description.

Muscavipula generally resembles the preceding, and is found in similar situations, but is vivacious, disclosing small ready-formed larvae instead of eggs, which in this species are hatched internally. This particularity is not confined to the present species, but has been observed in some others of this genus.

To this as well as to the preceding has been applied the observation, Tre musca consorunt ecundo et cepi quæcito ac loco; the number of flies proceeding from the flies, and the quick evolution of the successive broods, destroying the same quantity of flesh in a given time as the predacious quadruped, who devours a great quantity at certain intervals on those parts of the body, on which it continues with unremitting perseverance on the part of one or other of the respective races of flies. Of the hair-flies with bristled antennae, the musca grossa, the largest of European flies, affords a good example.
Musea flava, is one of the smallest but most elegant of the European flies; it is of a yellow colour, with bright gold-green eyes.

MUSCI, Mosser, one of the seven families or classes into which all vegetables are divided, is one of the Phylum Antho- komata, is the 2d order in the cryptogamic class, according to the sexual system.

The more perfect kinds of mosses are found in the shape of small but regular plants, divided into numerous filaments of the kind with leaves: these are of various forms and structures; some being broad and thin, others slender as hair; some belludic, others opaque; some smooth, others hairy. From the side of these leaves in some kinds, and from the summit of the stolts in others, there arise heads or capsules of various figure and structure, but all unicellular; some of these are naked, and others covered with a calyptra or hood; some stand on long pedicels, and others are placed close to the stalks. These heads are usually called capsule, which contain their seeds or spores; and their pedicels seta, in the musa, hypha, prophylls or pistillate of the plant, which rather in some are covered with a calyptra or hood; in others they are naked. Of the first kind are the sphagnum, polytrichum, ump, bryum, hypnum, kontium, and bethannia; and of the latter, the lycopodium, po-rella, spilagnum, and phascum.

Some of the mosses, it is evident, approach to the nature of the plants which have their male and female parts in the same flower, and others to those which have them in different ones. After all, this tribe of plants, as well as the mushrooms, ferns, and seaweeds, is still imperfectly known. The characteristics of these plants, however, according to the sexual system, are:

1. Tops without filaments or tendrils.
2. The male flower, constituted by the presence of the anther or tops, placed apart from the female, either on the same or distinct roots.
3. The female roots, flowers deprived of the pistil.
4. The seeds divided into both lobes (cotyledones) and proper coverings, so that they exhibit the naked embryo.

This order is subdivided into 13 genera, from the presence or absence of the calyx, which in this plant is a veil or cover like a monk's coat, that is placed over the male organs or tops of the stamens, and is dem- orticated calyptra, from the sexes of the plants, which bear male and female flowers, sometimes on the same, sometimes on distinct roots; and from the manner of growth of the female flowers, which are sometimes produced singly, sometimes in bunches or cones.

The manner of seeding of mosses in general, may be more clearly understood from the description of that genus of them which has been traced through all its stages, and which most of the others, though every genus has its distinct frictionat in some respects, yet bear a very general analogy.

The genus already observed, is that called by the botanists the hypnum. There is a species of this very numerous and common; but that particular one which was the subject of those observations, is the short-branched jelly kinds, common on old walls; and called by that author in his History, hypnum vul-
The insertion to be at E (Plate Miscel. fig. 188), near the wrist B, the muscle D, E being either loose and not bound down to it by some ligament or fascia R; in either of which cases the bone A cannot be turned up quite to the situation A, unless the muscle E is contracted, or shortened to D, M, which would not only be troublesome but even impossible. It would be troublesome, because the breadth and thickness of the arm would be vastly increased, so as to become as big as the belly of an animal. On the one hand, the structure of a muscle being such that it cannot be contracted but a little, seldom above two or three fingers' breadth; such an insertion as at E, which requires a contraction of about a foot and a half, would be altogether impossible. Therefore, in fact, we find the muscles inserted near the centre of motion, as at I, fig. 169.

In order to calculate the force of any muscle, we consider the bones or levers; and then the power or force of the muscle will be, always to the resistance or weight it is capable of raising, as the greater distance of the weight from the centre of motion is to the lesser distance.

Hence, it being found by experiments, that a robust young man is able to suspend a weight R, equal to twenty-eight pounds, when the arm is extended in a supine and horizontal situation, viz. the force of the muscle 1 D = to the weight R = 28 lb., as the distance D C is to the distance I C. But it is found, that D C, the length of the cubit and hand, is more than twenty times greater than I C, the distance of the muscle from the centre of motion. Therefore the force of the muscle 1 D, must be more than twenty times greater than the weight R, or more than 28 x 20 = 560 lb.

Again, to find the force which the biceps and brachialis muscles exert, when the humerus D A, (fig. 170.) is perpendicular to the horizon, we are first to consider what weight a man is accustomed to sustain in that posture, viz. R = 33 pounds, and next the quantity of the distances C B, C I, which in this case are as 10 to 1. Therefore the force of these muscles is to the weight R = 35 pounds, as the distance C B = to the distance I C = 1; or the force of the muscle is 500, as before.

But what appears most wonderful is, the force of the muscles that move the lower jaw; which, when taken altogether, do not in a man exceed the weight of 1 pound, and yet exert a force equal to 534 pounds, and in mastodons, wolves, bears, lions, &c. their force is vastly superior, so as to break large bones, as they practise daily in their feeding.

The motions of the far greater part of the muscles are voluntary, or dependant on our will; those of a few others, involuntary. The former are called animal, the other natural motions. Finally, the motions of some of the muscles are of a mixed kind, partly animal and partly natural.

Those muscles which perform the voluntary motions, receive nerves from the brain or spinal marrow: those which perform their motions involuntary, have their nerves from the cerebellum: and those whose motion is partly voluntary, and partly involuntary, have theirs in part from the brain, and in part from the cerebellum. And as a muscle can no longer act when the nerve in it is cut, asunder, or tied up, so the same absolute dependence it has on its artery: for from the experiments of Steno and others on living animals, it appears that in cutting or tying up the artery, the muscle in the same manner loses its whole power of action, as if the nerve had been cut or tied up.

**Muscovy Glass.** See Mica.

**Mushroom.** See Agaricus.

**Music.** A science which teaches the properties, dependances, and relations of melodious sounds; or the art of producing harmony and melody by the due combination and arrangement of those sounds. This science, when employed in searching the principles of this combination and succession, and the causes of the pleasure we receive from them, becomes very profound, and demands much patience, accuracy, and depth of thinking. It is generally supposed that the word music is derived from Muse, because it is commonly believed that an art of this kind is to be attributed to the muse; but Diocles derives it from an Egyptian name, intimating that music was first established as a science in Egypt after the Deluge, and that the earliest species of musical composition received from that produced by the seeds growing on the banks of the Nile, by the wind blowing into them. Others again imagine, that the first ideas of music were received from the working of birds. However this has not really been, it appears at least equally rational, to attribute its origin to mankind; since musical intonation, in the infancy of language, must often have been the natural result of passionate feeling, and since also we find that wherever there is speech there is song.

The antient writers on this science differ greatly as to its object and extent. In general, they give to it a much wider latitude than we do now. Under the name of music they comprehended not only the melodious union of voices and instruments, but also the dance, gesture, pantomime, and even all the other sciences. The ancient philosophers define music as the knowledge of order, which was also the doctrine of Plato, who taught that every thing in the universe was music.

Music, however, properly so called, only concerns the due order and proportion of sounds; and is divided into two parts, the theoretical and the actual. Theoretical music comprehends the knowledge of harmony and modulation; and the laws of that successive arrangement of sound by which air, or melody, is produced. Practical music is the art of bringing this knowledge and these laws into operation, by actually disposing of the sounds, both in combination and succession, so as to produce the desired effect; and this is the art of composition: but practical music may, in fact, be said to extend still further, and to include not only the production of melodious and harmonious composition, but also its performance; and to such a facility in execution, and neatness of expression has the denomination of practical music arrived at the present day, that its professors, generally speaking, hold a truly respectable rank in the various list of modern artists; and are highly, as well as most deservedly, esteemed by all lovers and patrons of the finearts.

**Musella.** An order of the plant kingdom, which consists of the genus Musella, or musk. It is generally supposed that the name Musella is taken from the Latin word Musella, which means musk, and it must be admitted that some of the species of this genus produce a musk-like odour. The European species, M. alba, M. neglecta, and M. obtusa, are the only ones which are of any importance. The musk of the Chinese species is more esteemed than that of the European. The musk is gathered in the autumn, and is dried, and kept in closed vessels. It is used in music to produce a delicious odour.
that this animal, the more effectually to conceal its retreat, contrives to make even this little air-hole in the midst of some thick bushes, and the principal entrance of the otter consists of fish, yet it is said that in hard weather, when this its natural prey fails, it will attack the smaller quadrupeds, as well as poultry, &c. The otter is naturally a very fierce animal; and when hunted with dogs, as is sometimes the practice, will inflict very severe wounds on its antagonists. The female produces four or five young at a birth; this commonly happens early in the spring. The young, if taken at a very early age, may be successfully tamed, and taught by degrees to hunt for fish, and bring them to their master.

When the otter, in its natural or uneducated state, has caught a fish, it immediately draws it ashore, and devours the head and upper parts, leaving the remainder; and when in a state of captivity, will eat no fish but what is perfectly fresh, but will prefer brook, milk, &c.

2. M. lutraola, the smaller otter, very much resembles the common otter, but is smaller; the body is of a dully colour, but with a considerable cast of tawny. In size it falls short of the other, measuring about a foot in length. In North America this species is known by the name of mink; and is said sometimes to leave the water, and prey on poultry, &c. in the manner of a polecat. It has two rows of sharp teeth and puncturing the blood. It is said also to have a fetid smell. In Europe the smaller otter is chiefly found in Poland and Lithuania, living on fish, frogs, &c. Its fur is very valuable, and next in beauty to that of the sable.

3. M. lutris, the sea otter, is the largest of the otters, measuring about 3 feet from the nose to the tail, and the tail thirteen inches. The colour of this species is a deep, glossy, brownish black, the fur being extremely soft and very fine; on the forehead is generally a cast of greyish or silver-colour. According to Mr. Pennant, it is one of the most local animals we are acquainted with, being entirely confined to between lat. 44. and 69. north; and between east long. from London, 125. to 150. inhabiting, in great abundance. Bering's islands, Kamtschatka, the Aleutian and Fox islands, between Asia and America. The habits of the Koreal islands, but are never seen in the channel between the north-east of Siberia and America. It is supposed that they bring but one at a time. They are most extremely harmless animals, and are singularly affectionate to their young. They bring forth on land, and often carry the young one between their teeth; fondle them; and frequently fling them up, and catch them again in their paws; and before they can swim, the parents take them in their bare feet, and swim about on their backs.

The young otter is wholly dependent on its parents till it takes a mate.

This animal is killed for its skin, which is one of the most valuable of furs, being sold at the rate of from 14 to 25 pounds sterling each. They are said to be chiefly sold to the Chinese.

The sea otter is sometimes taken with nets, but is more frequently destroyed with clubs and spears.

4. M. ferret, has eyes red and fiery. It inhabits Africa. In Europe it is tamed to catch rabbits, rats, &c. It procures twice a year, and brings forth from 6 to 8 at a time.

M. cujif, or the otter, is found in Europe, the cold parts of Africa, Asia, and China; lives in heaps of stones, banks of rivers, hollow trees, and forests, especially of heech; preys on squirrels, mice, and small birds. Body about ten inches long in front, when in northern climates becomes white, except the outer half of the tail, which remains black. The fur is very valuable. See Plate Nat. Hist. fig. 286. There are 28 species of the muskela.

MUTE. If any person being arraigned on any indictment or appeal for felony, or on any indictment for piracy, shall upon such arraignment stand mute, or will not answer directly to the felony or piracy, he shall be convicted of the offence, and the court shall thenupon award judgment and execution, in the same manner as if he had been convicted by verdict or confession; and by such judgment and execution the proceedings shall be dismissed as a conviction by verdict or confession.

12 G. III. c. 20.

And the law is the same with respect to an arraignment for petit treason or larceny, or for before this act, persons standing mute in either of the aforesaid cases, were to have the like judgment and execution as if they had confessed the indictment. 2 Inst. 177.

MUTILLA, a genus of insects, of the order hymenoptera; the generic character is, antennae illorum; &c. &c. The articulating obconic, erected on the tip of the lip; jaw membranaceous at the tip, lip projecting obconic; wings in most species obconic; body subpentac; thorax retuse behind; sting pungent, concealed. The M. holcena inhabits the Cape of Good Hope. See Plate Nat. Hist. fig. 287. There are 38 species.

MUST. See Fermentation.

MUSTISIA, a genus of the class and order syngeinae poli gania superfulia. The caly is cylindrical, rounded, car of the ray oval, oblong; of the disk, trid, down-feathered; recept. naked. There is one species, a climber of Peru.

MUTUAL PROMISE, is where one man promises to do anything to another, and in consideration thereof, promises to do a certain act, &c. &c. Such promises must be binding, as well on one side as the other; and both made at the same time. 1 Salk. 21.

MUTUS ET SURDUS, a person dumb and deaf, and being a tenant of a manor, the lord shall have the wardship and custody of him. But if a man be dumb and deaf, and have understanding, he may be grantor or grantee of lands, &c. 1 Co. Inst.

A prisoner who has been sentenced to the pillory, may be arraigned for a capital offence, if intelligence can be conveyed to him by signs or symbols. Leach's Gr. Law, 97. See Evidence.

MUTULIE. See Architecture.

MUTUUM, in the civil law, denotes a loan simply so called; or a contract introduced by the law of nations, whereby a thing consisting in weight, as bullion; in number, as money; or in measure, as corn, is given to a tenant, with the further stipulation, that he shall return another thing of the same quantity, nature, and value, on demand. This, therefore, is a contract with-out reward; so that where use or interest arises, there must be some particular article in the contract with which it is founded.

MUTINY, is a military sense, to rise against authority. Any officer or soldier who shall presume to use traitorous or disrespectful words against the sacred person of his majesty, or any of the royal family, is guilty of mutiny.

Any officer or soldier who shall behave himself with contempt or disrespect towards the general or other commander in chief of his forces, or shall speak words tending to such contempt or ill-nature, is guilty of mutiny.

Any officer or soldier who shall begin, excite, cause, or join in, any mutiny or sedi-}
MYC

Linnæus made a remarkable discovery relating to the generation of pearls in this fish. It is a fish that will bear removal remarkably well; and it is said, that in some places they form reservoirs for the purpose of keeping it, and taking out the pearls, which, in a few times, will again be renewed. From observations on the growth of their shells, and the number of their annular laminae or scales, it is supposed the fish will attain a very great age; for 63 years are imagined to be a moderate computation. The discovery turned on a method which Linnæus found, of putting these shell-fish into a state of producing pearls at his pleasure; though the final effect did not take place for several years; he says that in five or six years after the operation, the pearl would have acquired the size of a vetch. We are unacquainted with the means by which he accomplished this extraordinary operation.

MYAGRUM, Gold of Pleasure, a genus of the silicula order, in the tetranyx class of plants; and in the natural method ranking under the 20th order, siliqueae. The silicula is terminated by an orbicul shape; the cell garden having two or four species; but the most remarkable is the sativum, which grows naturally in cornfields in the south of France and Italy, and also in some parts of Britain. It is an annual plant; and is cultivated in Germany for the sake of the expressed oil of the seeds, which the inhabitants use for medicinal, culinary, and economical purposes. The seeds are a favourite food with geese. Horses, goats, sheep, and other beasts eat them.

MYCTERIA, the Jabiru, a genus of birds belonging to the order of grallae. The bill is long, bending upwards and acute; the nostrils are small and linear; there is no tongue; and the feet have four toes. There are two species: 1. The Americana, or American jabiru, is about the size of a turkey. See Plate Nat. Hist. fig. 238. The bill is long, stout, and of a black colour; the whole plumage is white, except the throat and breast, which are bare of feathers and of a blackish colour; the remainder is bare, and of a fine red; on the hind-head are a few greyish feathers; the legs are strong, of a great length in proportion to the body, clothed with black down and tail even at the end. This bird is found in all the savannas of Cayenne, Guiana, and other parts of South America. It is migratory and gregarious. It makes its nest in great trees, which grow on the borders; lays two eggs, and brings up the young in the nest till they can descend to the ground. The colour of the young birds is grey; the second year it changes to rose-colour, and the third to pure white. They are very wild and voracious, and their food is fish, which they devour in great quantities. The flesh of the young birds is said to be good eating, but that of the old is hard and oily. 2. The Atlántica, or Indus jabiru, is of a large size. The bill is dusky, almost straight above, and gibbous near the forehead; the under mandible swelled beneath; and from the base of the bill there passes through and beyond it a black streak, the whole colour of the plumage is white; the lower half of the back, the prime quills, and tail, are black; the legs a pale red. This species inhabits the Everglades, and feeds on nails.

MYGINDA, a genus of the tetranyx order, in the tetranyx class of plants; and in the natural method ranking with those of which the order is doubtful. The calyx is quadrangular; the petals four, the fruit a capsule. There are three species, shrubs of the West Indies.

MYOSOTIS, Scorpion-grass, a genus of the monogyna order, in the pentandria class of plants; and in the natural method ranking under the 20th order, ordine phanerogamia. The corolla is salver-shaped, quinquiseptal, and magnum; the throat siphon up by small arches. There are seven species, of which the most remarkable is the scorpions, or mouse-grass. This is a weed of Britain, growing naturally in dry fields, and margins of springs and rills. The blossoms vary from a full blue to a very pale one, and sometimes a yellow; and appear in a long spirally twisted spike. When it grows in the water, and its taste and smell are thereby rendered less observable, sheep will sometimes eat it; but it is generally fatal to them. Cows, horses, swine, and goats, refuse it.

MYOXUS, a genus of the polygyna order, in the pentandria class of plants; and in the natural method ranking under the 20th order, ordine phanerogamia. The calyx is pen-taphylous, the leaves cohering at the base; there are five subulate nectaria resembling petals; the seeds are numerous. There is one species, a weed.

MYXON, dormouse, a genus of quapu-rod's of the order glires: The generic character is, front-tooths two, the upper cuspated, the lower cusp four in each jaw; viscentia long; tail cylindric, villous, thicker towards the end; legs of equal length, fore-feet tetradactylous.

1. Myxurus gliis, fat dormouse: this species, the giss of Playf and the old naturalists, is a native of France and the South of Europe. It also occurs in Russia, Austria, &c. rising on trees, and leaping from branch to branch in the manner of a squirrel, though much less active in its movements. It feeds on nuts, acorns, fruit, &c. and during the greater part of the winter remains in a state of torpitude, awaking only at distant intervals. Its general length is about four inches and a half, and the tail rather less. It is of an elegant form, and from its peculiar posture it is called the little mouse beneath; the eyes are imbedded in a large black patch or spot, which extends to some distance beyond each ear; the tail is somewhat wider towards the end, and sharpens at the extremity and the paws are rather longer on the tip than on the other parts; the head, back, sides, belly, and tail, are of a tawny-red colour; the throat white; the fur is remarkably soft, and the whole animal has a considerable degree of elegance in its appearance. It sometimes happens that the colour is rather brown than reddish.

Dormice, says Mr. Pennant, inhabit woods or very thick hedges; forming their nests in the hollows of small trees, or near the bottom of a close shrub. As they want much of the sprightliness of the squirrel, they never rise to the tops of trees, or attempt to bound from spray to spray. Like the squirrel, they form little magazines of nuts, &c. for their winter provision, and take their food in the same upright posture. The consumption of their hoard during the rigour of winter is but small, for they sleep most part of the time, retiring into their nest of leaves, and rolling themselves up, lie torpid during the greatest part of the glummy season. Sometimes they experience a short revival in a warm sunny day, when they take a little food, and then refit back to their former state.
These animals seldom appear far from their retreats, or in any exposed situation; for which reason they seem less common in this country than they really are. They make their nest of grass, moss, and dead leaves. According to the count de Buffon, it consists of interwoven herbs, and is six inches in diameter, open only above, and is situated between the branches of hazel and bramble. The number of young is generally three or four.

**Myrica, Gale, or Sweet-willow**, a genus of the tetradnrdi order, in the direct class of plants, and in the natural method ranking under the 5th order, Anacardiatae. The scale of the male catkin is in the form of a crescent, without any corolla. The scale of the female catkin the same: there is no calyx; but two styles, and a monoporous berry.

1. The gale, Dutch myrtle, or sweet-willow, grows naturally upon bogs in many places both of Scotland and England. It rises about four feet high. The female flowers or catkins are produced from the tips of the branches, growing upon separate plants from the male, which are succeeded by clusters of small berries, each having a small seed. It flowers in July, and ripens in autumn. When transplanted into shrubberies, the moistest parts must be assigned to it.

The leaves, flowers, and seeds of this plant, have a strong fragrant smell, and a bitter taste. They are said to be used among the common people for destroying moths and cutaneous insects, being accounted an enemy to insects of every kind; internally, in infusions, as a stomachic and vermifuge; and as a substitute to hops for preserving malt liquors, which they render more aromatic, and of consequence less sublimable; it is said that this quality is destroyed by boiling.

2. The cereta, wax-bearing myrtle, or candleberry myrtle, is a native of North America, it is a small tree, about 10 or 12 feet high, with the female standing forth near the ground irregularly. The leaves grow irregularly on them all round; sometimes by pairs, sometimes alternately, but generally at unequal distances. The branches of the old plant are twigs of the same kind in the autumn; but the young plants raised from seeds retain them the greatest part of the winter, so as during that season, to have the appearance of an evergreen. But this beauty will not be lasting, for they shed their leaves proportionately earlier as the plants get older. There are both male and female trees of this sort: the flowers are small, of a whitish color, and make no figure; neither does the fruit. The fruits are the female (which is small, dry, blue berry), though produced in clusters, make any show; so that it is from the leaves this tree receives its beauty and value; for these being bruised, as well as the bark of the young shoots, emit the most refreshing and delightful fragrance, that is exceeded by no myrtle, or any other aromatic shrub. See Plate Nat. Hist. fig. 289.

There is a variety of this species of lower growth, with shorter but broader leaves, and of a fragrant odor. This grows commonly in Carolina; where the inhabitants pick from its berries a wax of which they make candles, and which occasion its being called the candleberry tree. It delights in a moist and soil. The wax is procured in the following manner: In November and December, when the berries are ripe, a man with his family will order some individuals to stand on sand-bank near the sea, where these trees most abound, taking with them kettles to boil the berries in. He builds a hut with palmetto-leaves for the shelter of himself and family during there, which is commonly four or five weeks. The man cuts down the trees, while the children strip off the berries into a porridge pot; and having put water to them, boil them till the oil flows, which is the sal volatile, into another vessel. This is repeated till no more oil appears. When cold, this hardness to the consistence of wax, and is of a dirty-green colour. They then boil it again, and clarify it in brass pan, which gives it a transparent greenness. These candles burn a long time, and yield a grateful smell. They usually add a fourth part of tallow, which makes them burn clearer. There are several other species.

**Myriophyllum**, a genus of the polyandria order, in the monogyna class of plants; and in the natural method ranking under the 15th order, Anacardiatae. The male calyx is tetraphyllous; there is no corolla; the stamina are eight in number. The female calyx is tetraphyllous; the pistil four; there is no stile; and four naked seeds. There are two species, aquatic of Europe.

**Myristica**, the nutmeg-tree; in botany, a genus of plants belonging to the class dicotyledons, and of the natural order Lamiaceae. The male calyx is monophyllous, strong, and parted into three lateral of an oval shape, and ending in a point: it has no corolla. In the middle of the receptacle rises a column of the height of the calyx; to the upper part of which the anthers are attached. They vary in number from three to twelve or thirteen. The female calyx and corolla, as in the male, on a distinct stem, the germen of an oval shape; the style short, the stigmatic stigma, the lacinate of which are oval and spreading. The fruit is of that sort called drupas. It is fleshy, roundish, sometimes unicolour, sometimes bicolour, and when ripe bursts at the side. The nutmeg is composed with a fleshy and fatty membranous substance, which divides into filaments; this, in one of the species is the mace of the shops. The seed or nutmeg is round or oval-shaped, unicolour, and contains a small kernel, variegated on the surface by the fibres running in the form of a screw.

There are five species of this genus according to some authors; but several of these being only varieties, may be reduced to three. viz. 1. *Myristica Fatua*, or wild nutmeg; the flowers in May, and rises to the height of an apple-tree; has oblong, lanceolate, downy leaves, and hairy fruit; the nutmeg of which is aromatic, but when given inwardly is narcotic, and occasions drunkenness, delirium for a time, and some occasional vomiting. The myristica sebiera, a tree frequent in Guiana, rising 40 or even to 60 feet high; on wounding the trunk of which, a thick, acid, red juice runs out. Anilbet says nothing of the nutmegs being aromatic; he only observes, that a yellow fat is obtained from them, which serves many medicinal and medical purposes, and that the natives make cakes of it. 3. The myristica aromatica, or nutmeg, attains the height of 30 feet by, producing numerous branches, which rise to the horizontal, and are covered with bark, which of the trunk is a reddish brown, but that of the young branches is of a bright green colour; the leaves are nearly elliptical, pointed, obtuse, obliquely nerved, on the upper side a bright green, on the under whist, and stand alternately upon footstalks; the flowers are small, and hang upon slender peduncles, proceeding from the axile of the leaves: they are both male and female upon separate trees.

The nutmeg has been supposed to be the concomium of Theophrastus, but there seems little foundation for this opinion; nor can it with more probability be thought to be the Dracaena of Galen. Our first knowledge of it was evidently derived from the Arabian; by Avicenna it was called Chivalon, or Jashbun, which signifies nut of Banda.

There are two kinds of nutmegs, the one male and the other female. The female is that in common use; the male is longer and more cylindrical, but it is of less aromatic flavour than the other. It is very subject to be worm-eaten, and by the Dutch it is strictly prohibited from being packed with the others, because it will give occasion to their being worm-eaten, too, by the insects getting from one species to the other. An almost exclusive and very lucrative trade in nutmegs from the island of Ceylon was carried on by the Dutch, but it is now transferred to the English, who have become masters of the colony.

The seeds or kernels called nutmegs are well known, as they have been long used both for culinary and medical purposes. Distilled with water, they yield a large quantity of essential oil, reconding in flavour the spice itself; after the essence is expressed a sebaceous matter is found swimming on the water; the decoction incipient, gives an extract of an unctuous, very light and bitterish, and with little or no aromaticity. Reepli- es such extract that of nutmegs by infusion, but elevates very little of it in distillation; hence the spirituous extract possesses the flavour of the spice in an eminently degree.

Nutmegs, when heated, yield the press a considerable quantity of liquid yellow oil, which on cooling concretes into a sebaceous consistence. In the shops we meet with three sorts of unctuous substances, called oil of mace, though really expressed from the nutmeg. The best is brought from the East Indies in stone jars; this is of a thick consistence, of the colour of mace, and has an agreeable fragrant smell; the second sort, which is pale-coloured, and much inferior in quality, comes from Holland in solid masses, generally flat, and of a square figure: the third, which is the worst of all, and is called common oil of mace, is an artificial composition of several palm oil, and the like, flavoured with a little genuine oil of nutmeg.

Method of gathering and preparing nutmegs.—When the fruit is ripe, the natives ascend the trees, and gather it by pulling
the branches to them with long hooks. Some are employed, in opening them immediately, and in taking off the green shell or first rid, which is laid together in a heap in the woods, where in time it putrifles. As soon as the putrification has taken place, the ant, or this kind of mushrooms, called boletiischwii, of a blackish colour, and much valued by the natives, who consider them as delicate eating. When the nats are stripped of their first rid, they are cut into pieces, and are carefully taken off with small knives. The mace, which is of a beautiful red, but afterwards assumes a darkish red colour, is laid to dry in the sun for the space of a day, and is then reduced to a place less exposed to his rays, where it remains for eight days that it may soften a little. They afterwards moisten it with seawater, to prevent it from drying too much, or from losing its oil. They are careful, however, not to employ too much water, lest it should become putrid, and be devoured by the worms. It is last of all put into small bags, and squeezed very close.

The nuts, which are still covered with their ligneous shell, are for three days exposed to the sun, and afterwards dried before a fre, till the smell, when shaken, they then beat them with small sticks in order to remove their shell, which flies off in pieces. These nuts are distributed into three parcels: the first of which contains the largest and most beautiful, which are destined to be brought to Europe; the second contains such as are reserved for the use of the inhabitants; and the third contains the smallest, which are irregular or untrue. These are burnt; and part of the rest is employed for procuring oil by pressure. A pound of them commonly gives three ounces of oil, which has the consistence of tallow, and has entirely the taste of nutmeg. Both the nut and mace, when divided, afford an essential, transparent, and volatile oil, of an excellent flavour.

The nutmegs which have been thus selected, would soon corrupt if they were not watered, or rather pickled, with lime-water mixed with salt. To this end, they are washed with salt water till it attains the consistence of fluid paste. Into this mixture they plunge the nutmegs, contained in small baskets, two or three times, till they are completely covered over with the liquor. They are afterwards laid in a heap, where they heat, and lose their superfluous moisture by evaporation. When they have sweated sufficiently, they are then properly prepared, and are kept for sale.

The aromatic qualities of nutmeg are supposed to be aromatic, anodyne, stimulac, and astrignent; and with a view to the last mentioned effects, it has been much used in diarrhoea and dysentery. To many people the aromatic flavour of nutmeg is very agreeable: but some, however, should be cautious not to use it in large quantities, as it is apt to affect the head, and even to manifest an hypnotic power: such a degree as to prove extremely dangerous. Botanists speak of this as a frequent occurrence in India; and Dr. Cullen relates a remarkable instance of this soporific effect of the nutmeg, which fell under his own observation, and hence concludes, that in apoplectic and paralytic cases this spice may be very improper. He observes that a person by mistake took two drams of a little more of powdered nutmeg; he felt it warm in his stomach, without any nausea; but in about an hour after he had taken it, he experienced a drowsiness, which gradually increased to a complete stupor and insensibility; and not long after he was found fallen from his chair, lying on the floor of his chamber in the state manifesting he had fell asleep; but waking a little from time to time, he was quite delirious; and he thus continued alternately sleeping and delirious for several hours. By degrees, however, both these symptoms diminished; so that in about six hours from the time of taking the nutmeg he was pretty well recovered from both. Although he still complained of head-ache, and some drowsiness, he slept naturally and quietly the following night, and next day was quite recovered.

The official preparations of nutmeg are, a spirit and essential oil; and the nutmeg in substance roasted, to render it more astrigent. Both the space itself and its essential oil contain several compositions, as the confectionary, aromatic, spicaria, and mace, &c.

Mace possesses qualities similar to those of the nutmeg, but is less astrigent, and its oil is supposed to be more volatile and acrid.

MYRMEICA, a genus of the class and order termitaria monogyna; the calyx is tubular, five-toothed; cor., one-petalled; gern five glands at the base; stigma bilatera. This is one species, a shrub of Guiana.

MYRMECOPHAGA, Ant-eater, a genus of quadrupeds of the order bruta. The generic character is, teeth none; tongue cylindrical, extend; mouth lengthened into a somewhat tubular form; body covered with hair. The animals of this genus live entirely on flesh, and are armed with the most kinds of ants; in order to obtain which, they extend their tongue, which is of a very great length, and of a roundish or wormlike form, into the nests of these insects; and when, by means of the saliva by means of which it is covered, a sufficient number are secured, they retract it suddenly into the mouth, and swallow them. A part of the generic character of the myrmecophaga is the total want of teeth, in which particular it resembles no other animals except those of the genus manis, in which the same circumstance takes place. There are, however, in the ant-eaters, according to the observations of Mons. Brongersum, certain bones or processes not unlike teeth, situated deep at the entrance of the gullet; or oesophagus; or rather, according to the celebrated Camper, at the lower end of the jaws. The species of ant-eaters are not numerous.

1. Myrmecophaga jabata, great ant-eater. This is by far the largest of the ant-eaters, being upwards of seven feet in length, from the tip of the nose to the end of the tail; but if measured to the origin of the tail, it is no more than six feet long. It is said to be a very slow animal of an uncouth appearance; the head is small; the snout very long; the eyes small; the ears short and round; the shoulders thick and muscular, from whence the body tapers towards the tail; but the thighs are thick and stout; the colour of the animal is a deep grey, with a very broad band of black running from the neck downwards on each side the body, growing gradually narrower as it passes down; this black band is accompanied by the yellow at the anterior part of the tail; the fore legs are of a lighter cast than the hinder; and have a patch of spot of black in front not much above the foot; the tail is black, extremely long and bushy; the hair on the whole body, but especially on the tail, is very harsh and coarse; there are four toes on the fore-feet, and five on the hind: the two middle claws of the fore feet are extremely large and strong; which render this creature, though destitute of teeth, a very formidable adversary; since it has been known to destroy animals of much greater apparent strength than itself; fixing its claws upon them, and exerting such powerful strength as to kill them by continued laceration and pressure.

2. Myrmecophaga douba, little ant-eater. This is an animal of great elegance. It is not superior in size to a squirrel; measuring little more than seven inches from the nose to the tail, which is longer than the body and head. The head is small; the snout sharpened, and slightly bent downwards; the legs are short; the fore feet have only two claws on each, the exterior one much larger and stronger than the interior; on each of the hind feet are four claws of moderate size; the ears are very small, and hid in the fur; the eyes are also small. The whole animal is covered with a beautiful soft, and somewhat crisped or curled fur, of a pale yellow colour, or rather yellow-brown; the tail, which is very thick at the base, gradually tapers to the tip; and the lower surface, for about the space of four inches from the tip, is bare; the tail in this species being prehensile, and the animal commonly residing on trees, and preying on ants, by means of its long tongue, in the manner of other species. It is a native of Guiana. See Plate Nat. Hist. fig. 290.

3. Myrmecophaga aculeata, aculeated ant-eater. The aculeated ant-eater is one of those curious animals which have been lately discovered in the vast island, or rather continent, of Australia or New Holland; and is a striking instance of that beautiful gradation, so frequently observed in the animal kingdom, by which creatures of one tribe or genus approach to those of a very different one. It forms a connecting link between the very distant Linncean genera of hysteris (porcupine) and Myrmecophaga (ant eater). The external coating and general appearance of the one, with the mouth and peculiar generic characters of the other. This animal, so far as may be judged from the specimens hitherto imported, is about a foot in length.
In its mode of life this animal resembles the rest of the ant-eaters, being generally found in the midst of some large ant-hill; it burrows with great strength and celerity under ground, when disturbed; its feet and legs being most excessively strong and short, and not adapted for this purpose. It will even burrow under a pretty strong pavement, removing the stones with its claws; or under the bottom of a wall. During these exertions, its body is strengthened or lengthened to an uncommon degree, and appears very different from the short or platy aspect which it bears in its undisturbed state.

It cannot escape the observation of every scientific naturalist, that, in consequence of the discovery of this curious animal, the Linnaean character of myrmecophaga is, in part, rendered inapplicable. Since, therefore, the genera of manis and myrmecophaga differ only in the external covering (the former being coated with scales, and the latter with hair), it would, perhaps, be proper to conjoin the two genera, to add this as a new species, and to give as part of the generic character, corpus pilosum, squamis vel acuminis tarsi. Or it might even constitute a new genus, which would differ essentially from manis and myrmecophaga, in having the body covered with spines.

*MYRMELEON*, a genus of insects of the order myrmeleont; the generic character is, mouth furnished with jaws, tender towards feeders four, elongated; stenoma none; antennae elevated, of the length of the thorax; wings detached; tail of the male furnished with a tuft consisting of two straight or filiform filaments. Of this genus into the specific history is best understood is the myrmecolean formicaleo of Linnæus, whose larva has long been celebrated by naturalists for its wonderful ingenuity, in preparing a kind of pitfall or deceptive cavity for the destruction of such insects as happen unawarly to enter it. The myrmecolean formicaleo, in its complete or fly state, bears no inconsiderable resemblance to a small spider, from which, however, it may readily be distinguished by its antennae. It is of a predacious nature, flying chiefly by night, and pursuing the smaller insects in the manner of a lubidula. It deposits its eggs in dry sandy situations; and the young larva, when hatched, continues to perform the same talent of preparing, by turning themselves rapidly round, a very small conical cavity in the sand. Under the centre of the cavity the little animal conceals itself, suddenly rushing forth at intervals in order to seize any small insect which, by approaching the edge of the cavity, has been so unfortunate as to fall in; and after sucking out its juices through its tubular forceps, throws it by a sudden exertion to some distance from the cavity. As the creature increases in size it enlarges the cavity, which at length becomes about two inches or more in diameter. The larva, when full-grown, is more than half an inch long, and is of a flattened figure, broad towards the upper part, and gradually tapering to an obtuse point at the extremity. It is of a brown colour, and beset with numerous tufts of dusky hair, which are particularly conspicuous on the crown of the head and abdomen; the legs are slender; the head and thorax rather small; the tubular jaws long, curved, serrated internally, and very sharp-pointed. The whole animal is of an unpleasing aspect, and on a cursory view bears a general resemblance to a flat-bodied spider. When magnified, its appearance is highly uncouth.

The ingenious Reaumur and Robel have given accurate descriptions of this larva and its external history. But this insect, whose term of life, like that of the lubiduleae and eumeneae, is protracted to a very considerable space, since it survives the winter in its larval state, taking no nourishment during that time, and in the spring resumes its usual manner of preying. In preparing its pit, it begins by tracing an exterior circle of the intended diameter of the cavity, continuing its motion, in a spiral line, till it gets to the centre, thus marking several volutes in the sand, resembling the impression of a large helix or snail-shell; and after having sufficiently deepened the cavity by a repetition of this motion, it smooths the sides into a regular shape by throwing out the superfluous material on the surface. While this its perforation is being made, it leaves the cavity, and in a few moments, when in near, a foot beyond the brink. The depth of the pit is generally equal to the diameter. When full-grown and ready to change into a chrysalis, the animal coves itself in a fibrous round ball, and is furnished with a tuft coiled round by very fine silk, which it draws from a tubular process at the extremity of the body; with this silk it also lines the internal surface of the ball, which, if opened, appears covered by a fine heart-coloured silken tissue, that continues in the state of chrysalis about four weeks, and then gives birth to the complete insect.

The myrmecolean barbarus has antennae as long as the body; thorax spotted with yellow. See Plate Nat. Hist. fig. 291.

*MYRROBALANS*, a kind of medicinal fruit brought from the Indies. See Materialia Medica.

*MYRODENDRUM*, a genus of the class and order poyandia monogyna. The cor. is five-petaled, stam. five; per. five-celled. There is one species, a tree of Guiana.

*MYRORIA*, a genus of the monandaphia poyandia class and order; the calyx is single, one-leaved; cor. five-petaled; pist. one. There are two species, shrubs of the West Indies.

*MYROSMA*, a genus of the monandaphia monogyna class and order; the calyx is double, outer three-leaved, inner three-petaled; cor. five-petaled; caps. three-cornered. There is one species, a shrub of Surinam.

*MYRXOXYLM*, a genus of the monogyna order, in the decandra class of plants. The calyx is campanulate; the superior petal larger than the rest; the gum is longer than the corolla; the legumin monoepernous. There is but one species, the penitiperum, a native of Peru and the warmer parts of Africa. It is this shrub that yields the essence of the balsam, being exsicated by the action of the sun, and exsicated from it by evaporation in water. This balsam, as brought to us, is nearly of the consistence of thin honey, of a reddish brown colour inclining to black, an agreeable arome, and a very hot bitters taste. Distilled with water, it yields a small quantity of a fragrant essence of a reddish colour; and in a strong fire, without addition, a yellowish red oil. Balsam of Peru is a very warm aromatic medicine, considerably stronger than eucalyptus. (See Balsam.) It possesses the principal effects of warm the habit, to strengthen the nervous system, and attenuate viscid humours. Hence its use in some cases of asthma, gonorrhœa, dysenteries, and other disorders proceeding from a debility of the skin, or sluggishness and inactivity of the juices. It is also employed externally, for cleansing and healing wounds and ulcers, and sometimes against piles and rheumatic pains. There is another sort of balsam of Peru of a white colour, and considered more fragrant than the former. This is very rarely brought to us. It is said to be the produce of the same plant which yields the common or black balsam; and to experience less incisiveness made in the trunk, while the former is obtained by boiling. There is also a third kind, commonly called the red or dry. This is supposed to obtain a different state from the white, merely in consequence of the juice. It is subjected after it is got from the tree. It is almost as fragrant as the balsam of Gilead, held in so high esteem among the Eastern nations. It is very rarely in use in Britain, and almost never to be met with in our shops.

*MYRRH*, a gummy resinous concrete juice. The plant from which this substance is obtained, is not certainly known. According to some it belongs to the genus myrrha, and grows in Abyssinia and Arabia. It is in the form of tears. Colour reddish-yellow, sometimes transparent, but more frequently opaque. Taste bitter and aromatic. Does not melt when heated, and burns with difficulty. With water it forms a yellow solution. The solution in alcohol becomes opaque when mixed with water. By distillation it yields oil. Its specific gravity is 1.36. It is said to be employed in medicine, and is soluble in alcohols.

The medical effects of this aromatic bitter are, to warm and strengthen the viscera; it frequently occasion a mild diarrhœa, and it is used in a general way. It seems that proves serviceable in languid cases, diseases arising from a simple inactivity, catarrhal disorders, and where the lungs and thorax are oppressed by viscid phlegm.

Rectified spirit extracts the fine aromatic flavour and bitterness of this drug, and does not elevate any thing of either in evaporation; the gummy substance left by this men- struum has a disagreeable taste, with scarcely any of the particular properties of myrrh; this part dissolves in water, except some impurities which remain. In distillation with water, a considerable quantity of a ponderous essential oil arises, resembling in flavour the original drug. Myrrh is the basis of an official tincture. It enters the pilule: a lae circum: myrrha, the pilule e gingumi, the pilule stoma- machica, and other formule.

*MYRSINE*, a genus of the monogyna class of plants, and in the natural method ranking under the 18th order, bicornes. The corolla is semilinquiniated and coonvolute; the germen filling the corolla; the berry quinquelocular and
See Myrtus.

MYRTUS, the myrtle, a genus of the monogynous order, in the icosaedra class of plants; and in the natural method ranking under the 19th order, hesperide. The calyx is quinquedent, superior; there are five petals; the berry is dispersive or dispersum. There are 36 species, of which the most remarkable are:

1. The communis, or common myrtle-tree, of which the most material varieties are:

- Broad-leaved, with ovate, or oval, pointed, green leaves, an inch and a half long, and one broad; and which is remarkably floriferous. Gold-striped broad-leaved Roman myrtle. Broad-leaved Dutch myrtle, with brightly colored, blue-blotched green leaves, an inch long, and about three quarters of one broad. Double-flowered Dutch myrtle. Broad-leaved Jew's myrtle, having the leaves placed by threes at each joint, the leaves are thick, those of the common myrtle. This latter variety of this species is in universal estimation among the Jews in their religious ceremonies, particularly in decorating their tabernacles; and for which purpose many gardeners set it out. The leaves and branches are of particular care to sell to the above people: for the true sort, having the leaves exactly by threes, is very scarce, and is a curiosity; but by care in its propagation, taking only the perfectly formed leaves and branches, it may be increased fast enough; and is worth the attention of the curious, and particularly those who raise myrtles for the London markets. Orange-leaved Spanish myrtle, myrtle, with oval, stippled leaves, an inch and a half long, or more, and one broad, in clusters round the branches, and resembling the shape and colour of orange-trees. Leaves. Gold-striped-leaved orange myrtle, a variety of the common upright myrtle, with its branches and leaves growing more erect, the leaves oval, lanceolate, acute-pointed, and near an inch long and half one broad. Silver-striped upright Italian myrtle, with oval, stippled leaves, the Portugal acute-leaved, myrtle, with spear-shaped, oval, acute-pointed leaves, about an inch long. Box-leaved myrtle, with weak branches, and small oval, obtuse, lobate, green leaves. Striped, silver leaved myrtle. Rosemary-leaved myrtle. Silver-striped rosemary-leaved myrtle. Thyme-leaved myrtle, with very small close-placed leaves. Nutmeg-myrtle, with erect branches and leaves; the leaves oval, acute-pointed, and thinly scented like a nutmeg. Broad-leaved nutmeg-myrtle. Silver-striped-ditto. Cristate or cockscomb myrtle, frequently called by this name, and it is a beautiful evergreen shrub, of exceeding fragrance, exotics originally of the southern parts of Europe, and of Asia and Africa, and consequently in this country require a shelter of a greenhouse in winter.

2. The pimenta, pimento, Jamaica pepper, or allspice tree, grows about 30 feet in height and two in circumference; the branches near the top are much divided and thickly beset with leaves, which by their continual verdure always give the tree a beautiful appearance; the bark is very smooth externally, and of a grey colour; the leaves vary in shape and size, but are commonly about four inches long, veined, pointed, elliptical, and of a deep shining green colour; the flowers are in branches or panicles, and stand upon subdividing or trichotomous stalks, which usually terminate the branches; the calyx is cut into four roundish segments; the petals are also four, white, ovate, red-stemmed, and opposite to each other between the segments of the calyx; the filaments are numerous, longer than the petals, spreading, of a greenish-white colour, and rise from the calyx and upper part of the gearment. There are roundish, and of a pale yellow colour; the style is smooth, simple, and erect; the stigma is obtuse; the germen becomes a round succulent berry, containing two kidney-shaped flatish seeds. This tree is a native of New Spain and the West India islands. In Jamaica it grows very plentifully; and in June, July, and August, puts forth its flowers, which, with every part of the tree, breathe an aromatic fragrance. The berries when ripe are of a dark purple colour, and full of a sweet pulp, which the birds devour greedily. The pimento is a most beautiful odoriferous evergreen, and exhibits a fine variety in the fruits at all seasons.

MYRTILUS, the mussel, a genus of animals belonging to the order of veneres testacei. The animal is an ascidia; the shell bivalve, often affixed to some substance by a broad; the hinge without a tooth, marked with a long, hollow line. Of these animals there are a great many species, some of which inhabit the seas, others the rivers and ponds. Several of them are remarkable for the beauty of their internal shell, and for the pearls which are sometimes found in them.

1. The edulis, or edible mussel, has a strong shell, slightly incurvated on one side, and angulated on the other. The end near the hinge is pointed, the other rounded. When the epidermis is taken off it is of a deep-blue colour. It is found in immense beds, both in deep water and above low-water mark. This species inhabits the European, and Indian tropics; it is the largest, and smaller within the polar circle. It is said to be hurtful if too often eaten, or in too great quantities.

2. The anatis, or duck mussel, has a shell more oblong and less convex than the last; it is very brittle and semitransparent; the space round the hinges like the last; the length about five inches, breadth two. It is found in Europe in fresh waters. Both it and the cygus are diversified by swans and ducks, whence their names; crosses also feed on these mussels, as well as on different other shell-fish; and it is diverting to observe, that when the shell is hard for their bills they fly it with a graceful flight, drop the shell on the water, and at last draw itself out of the shell by the fall.

3. The violaceus, or violet mussel, has the shell longitudinally furrowed, the run very obese, somewhat formed like the mytilus edulis, but considerably larger and more flattened, of a beautiful violet-colour. Inhabits the southern ocean.

4. The marapagia forms the true mother-of-pearl, and frequently the most valuable pearls; the most common are green, or emerald, or blue-colour with white rays; when the outer coat is removed it has the same lustre as the inside; the younger shells have ears as long as the shell, and resemble scallops.

There are between 50 and 60 other species. Mussels not only open and shut their shells at pleasure, but they have also a sliding motion; they canfasten themselves where they please; they respire water like the fishes; and some even flattter about on its surface so as to inhale air. If they lie in shallow waters they sink on the land; if in deep, then they fly them above the heel of the shell, and a few moments after they cast out the water by one single stroke at the other end of the shell. The mouth is situated near the sharp angle of the outer valve; they open with it to raise fringes in the shape of mustachios, which may perhaps answer the purpose of lips.

The bars which surround the edge of almost half the mussel, are a wonderful web of bollorium which they form in the organ of respiration, as vessels for the circulation of the fluids; and probably, as some philosophers suppose, as wedges for opening their shells; for we observe two large muscles or tendons for the purpose of shutting them; but we in vain look for their antagonists, or those which are destined to open them. When the mussel wishes to open itself, it relaxes the two muscles or tendons, and swells the fringes, which act as wedges, and separate the shells. The animal shuts up itself by the contraction of two thick fibrous muscles, which are fixed internally to each end of the shell; and these shells are covered with a membrane or epidermis, which unites them together when they are sealed in water, that not the smallest drop can escape from the mussel. When mussels choose to stick they oblong themselves on the sharp edge of their shells, and put forth a fleshy substance susceptible of extension, which serves them as a leg to drag themselves along, in a kind of groove or curved hollow, and these shellers are sometimes used with a membrane or epidermis, which unites them closely together when they are sealed in water, that not the smallest drop can escape from the mussel. When mussels choose to stick they oblong themselves on the sharp edge of their shells, and put forth a fleshy substance susceptible of extension, which serves them as a leg to drag themselves along, in a kind of groove or curved hollow, and these shellers are sometimes used with a membrane or epidermis, which unites them closely together when they are sealed in water, that not the smallest drop can escape from the mussel. When mussels choose to stick they oblong themselves on the sharp edge of their shells, and put forth a fleshy substance susceptible of extension, which serves them as a leg to drag themselves along, in a kind of groove or curved hollow, and these shellers are sometimes used with a membrane or epidermis, which unites them closely together when they are sealed in water, that not the smallest drop can escape from the mussel.
N, or n, the thirteenth letter of our alphabet; as a numeral stands for 900; and with a dash over it, thus N, for 9,000,000. N°. 114, nails for number, i.e. in number; and N. B. for nota bene, note well. Among the ancient Romans, N. denotes Nepos, Nonius, &c. N. C. Nero Caesar, or Nero Claudius; N. L. Non liquis; N. P. Notarius Publicus; and NBL stands for nobilis.

NADIR, in astronomy, that point of the heavens which is diametrically opposite to the zenith, or point directly over our heads. NADIRAS: a genus of the monandra order, in the discica class of plants; and in the natural method ranking with those of which the order is doubtful. The male calyx is cylindrical and broad; the corolla quadrifid; there is no filament, nor is there any female calyx or corolla; there is one pistil, and the capsule is ovate and unilocular. There is one species, an aquatic of the South of Europe.

NAIL, anguis. See Anatomy, and History.

NAILS, in building, &c. small spikes of iron, brass, &c, which being driven into wood, serve to bind several pieces together, or to fasten something upon them. The several sorts are very numerous; as, 1. back and bottom nails, which are made with flat shanks to hold fast, and not open the wood. 2. Clench-nails, for fastening the clamps in buildings, &c. 3. Clasp-nails, whose heads clapping and sticking into the wood, render the work smooth, so as to admit a plane over it. 4. Clench-nails, used by boat and barge-builders, and proper for any boarded buildings that are to be taken down; because they will drive without splitting the wood, and draw without breaking; of this there are many sorts. 5. Clout-nails, used for nailing on clouts to axles-trees. 6. Deck-nails, for fastening decks in ships, doubling of shipping, and floors of buildings. 7. Dog-nails, for fastening hinges on doors, &c. 8. Flat-points, much used in shipping, and proper where there is occasion to draw and hold fast, and no conven ience of clenching. 9. Jabot-nails, for nailing thin plates of iron to wood, as small hinges on cupboard-doors, &c. 10. Lead-nails, for nailing head, leather, and canvas, to hard wood. 11. Port-nails, for nailing linens to the ports of ships. 12. Pound-nails, which are four square, and are much used in Essex, Norfolk, and Suffolk, and scarcely any where else long, which sit tight in a spiral direction, and with which it sucks the substance of the mussel. Mussels are also subject to certain diseases, which have been supposed to be the cause of those bad effects which sometimes happen from the eating of them.

MYXINE, the hog; a genus of insects belonging to the order of vermox intestini. It has a slender body, carinated beneath; mouth at the extremity, ciliated; the two jaws pinnated; an adspose or rayless fin round the tail and under the belly. The only remarkable is the glutinos, about eight inches long. It inhabits the ocean; enters the mouth of fish when on the books of lines that remain a tide under water; and totally devours the whole, except the head. The Scarborough fishermen often take it in the robbed fish, when drawing up their lines. Limnaeus attributes to it the property of turning water into gube.

NAPEA, a genus of the polyandra order, in the polydeipha class of plants; and in the natural method ranking under the 37th order, columnifere. The calyx is single and cylindrical; the calyx-cells are monoecious and monosporous. There are two species; both of them with perennial roots. Both of them are natives of Virginia and other parts of North America; from the bark of some of the Indian kinds a sort of paper might be procured, capable of being woven into very strong cloth. They are easily propagated by seed, which will thrive in any situation.

NAPTHA a name given to the most liquid bitumens; it is light, transparent, and very inflammable. There are several varieties, found chiefly in Italy, and particularly near Modena. Kempfer, however, says, that great quantities are collected in several parts of Persia; naturalists attribute the formation of the liquid bitumens to the decomposition of those that are solid, by the action of the subterraneous fires. Naphtha is said to be the lightest, which the fire first discengages; it is very volatile, and so combustible, that it catches fire when being brought near it. In Persia, this and the other bitumens are employed for the purpose of giving light in lamps by means of wicks; they may be used also to give heat; for this purpose some naphtha are pared on a few handfuls of earth, and kindled with paper, when it burns briskly, but diffuses a thick smoke, which adheres to everything, and leaves a disagreeable smell. In India, the flame produced by it is wosintered, and the heat it emits is used for dressing victuals; and in some cases it has been successfully employed in paralytic diseases. See Bitumen.

NARCIISSUS, a genus of the monogyonia order, in the hexandra class of plants; and in the natural method ranking under the 9th order, spathaceae. There are six petals; the nectarium is funnel-shaped and monophyllous; the stamens are within the nectarium. There are 15 species; the most remarkable are:

1. The bastard narcissus, or common yellow English daffodil, grows wild in great plenty in many of our woods and meadows, and under hedges, in several parts of England. Its commonness renders it of but
little esteem with many; considered, however, as an early and elegant flower, of exceeding hardiness and easy culture, it merits a place in every garden, especially the double.

2. The biolar, or two-coloured inapplicable narcissus; the varieties are, commonly, single-double-flowered, with the interior petals some white, and some yellow, with sulphur-coloured flowers.

3. The poetis, poetis daubolii, or common white narcissus, is well known. Of this there are varieties with purple-capped petals, yellow petals, double-flowered; all of them with white petals. It is the antient celebrated narcissus of the Greek and Roman poets, which they so greatly extol for its extreme beauty and fragrance.

4. The bullcoccus. From the large spreading nectarium of this species, which is three or four times longer than the petals, narrow at bottom, and widening gradually to the brim, so as to resemble the shape of some old-fashioned hoop petticoats, it obtained the name hoop-petticoat narcissus.

5. The serotinis, or late-flowering small autumnal narcissus.

6. The tazetta, or multiflorous daubolii, commonly called polyanthus narcissus. The varieties of this are very numerous, consisting of about eight or nine principal sorts; each of which has many intermediate varieties, amounting in the whole to greatly above a hundred in the Dutch florists' catalogues, each variety distinguished by a name according to the fancy of the first raiser of it. They are all very pretty flowers, and make a charming appearance in the flower-borders, &c.; they are also finely adapted for blotting in glasses of water, or in pots, to ornament rooms in winter.

7. The jonquilla, or jonquill, sometimes called rush-leaved daubolii. The varieties are, jonquill minor with single flowers; jonquill major with single flowers, starry-flowered, yellow and white flowers, white-flowered, semi-double-flowered, double-flowered, and large double inodorous jonquill; all of them multiflorous, the single in particular; but some varieties, the doubles produce only two, or three flowers from a spath, and the singles commonly six or eight. All the sorts have so fine a shape, so soft a colour, and so sweet a scent, that they are among the most agreeable spring-flowers.

8. The calathus, or multiflorous yellow narcissus.

9. The odoros, oloriferous, or sweet-scented starry-yellow narcissus.

10. The triandrus, or triandrus rush-leaved white narcissus.

11. The trilobus, or trilobate yellow narcissus.

12. The minor, or yellow winter dasolfii.

NARCIOTICS, in medicine, soporiferous medicines, which excite a stupefaction. See the next article.

NARCOTIC PRINCIPLE. It has been long known, that the milky juices which exude from certain plants, as the poppy, lettuce, &c. and the infusions of others, as of the leaves of the digitalis purpurea, have the property of exciting sleep, or, if taken in doses producing a state of apoplexy, or blinding apoplexy, and terminating in death. How far these plants owe these properties to

NARCIOTIC PRINCIPLE. It has been long known, that the milky juices which exude from certain plants, as the poppy, lettuce, &c. and the infusions of others, as of the leaves of the digitalis purpurea, have the property of exciting sleep, or, if taken in doses producing a state of apoplexy, or blinding apoplexy, and terminating in death. How far these plants owe these properties to

certain common principles which they possess, is not known, though it is exceedingly probable that they do. But as a peculiar substance has been detected in opium, the most noted of the narcotic preparations, which possesses peculiar properties in portions in potion, we are warranted, till further experiments elucidate the subject, to consider it as the narcotic principle, or at least as one species of the substances belonging to this genus.

Dil. This narcotic is obtained from the poppy album, or white poppy, a plant which is cultivated in great abundance in India and the East. The poppies are planted in a fertile soil, and well watered. After the flowering is over, and the sepal &c. are digested, and their full size, a longitudinal incision is made in them about sun-set for three or four evenings in succession. From these incisions there flows a milky juice, which soon concretes, and is brought into cakes. In this state it is brought to Europe.

Opium thus prepared is a tough brown substance, has a peculiar smell, and a nauseous bitter acid taste. It becomes softer when held in the hand, burns very readily and strongly. It is a very compound substance, containing sulphur of lime, sulphat of potass, an oil, a resinous body, an extractive matter, glutinous fibres, &c. besides the peculiar narcotic principle to which probably it owes its virtues as a narcotic.

When water is digested upon opium, a considerable portion of it is dissolved, the water taking up several of its constituents. When this solution is evaporated to the constience of a syrup, a gritty precipitate begins to appear, which is considerably increased by diluting the liquid with water. It consists of the several ingredients: namely, resin, oxygenized attractive, and the peculiar narcotic principle which is crystallized. When alcohol is digested on this precipitate, the resin and narcotic substances are taken up, while the oxygenized attractive remains behind. The narcotic principle falls down in crystals as the solution cools, still however coloured with resin. But it may be obtained tolerably pure by repeated solutions and crystallizations.

Water is incapable of dissolving the whole of opium. What remains behind still contains a considerable portion of narcotic principle. When alcohol is digested on this residue, it acquires a deep red colour; and deposits, on cooling, crystals of narcotic principle, coloured by resin, which may be purified by repeated crystallizations. The narcotic principle obtained by either of these methods possesses the following properties:

Its colour is white. It crystallizes in rectangular prisms with rhomboidal bases. It has neither taste nor smell.

It is insoluble in cold water, soluble in about 400 parts of boiling water, but precipitates again as the solution cools. The solution in boiling water does not affect vegetable blues.

It is soluble in 24 parts of boiling alcohol and 100 parts of cold alcohol. When water is mixed with the solution, the narcotic principle precipitates in the state of a white powder.

Hot ether dissolves it, but lets it fall on cooling.

When heated in a spoon it melts like wax. When distilled it froths, and emits white va-
pours, which condense into a yellow oil. Some water and carbonat of ammonia pass into the receiver; and at last carbonic acid gas, ammonia, and carburetted hydrogen gas, are disengaged. There remains a bulky coal, which yields traces of potass. The oil obtained by this process is viscous, and has a peculiar aromatic smell and an acid taste.

It is very soluble in all acids. Alkalies throw it down from these solutions in the state of a white powder. Alkalies render it rather more soluble in water. When they are saturated with acids, the narcotic principle falls down in the state of a white powder, which is redissolved by adding an excess of acid.

Volatile oils, while hot, dissolve it; but, on cooling, they let it fall in an oleaginous state at first, but it gradually crystallizes. If the oil had effects were counteracted by causing the animals to swallow vinegar. This substance is known to be of equal service in counteracting the effects of opium. Derosee used doses that the efficacy of the oil may either be owing to the readiness with which it dissolves the narcotic principle.

Many other substances besides opium possess narcotic virtues; but hitherto they have not been treated by chemists with much attention. The most remarkable are the following:

1. The lactuca virosa, and the sativa or garden-lettuce, and indeed all the lactuca, yield a sticky juice, which, when properly extracted, has very much the appearance of opium, and possesses the same properties. Indeed, Dr. Coxe of Philadelphia affirms, that as good opium may be obtained from the garden-lettuce as from the poppy. It is obtained by incisions at the time when the lettuce is running to seed. The resemblance between the insipid juice of the lactuca virosa and opium is striking.

2. The leaves of the Digitalis purpurea, or fox-glove, are still more powerful than opium. It has been observed that the digitalis, when digested, or distilled, yields the following substances:

3. The leaves of the Digitalis purpurea, or fox-glove, are still more powerful than opium. It has been observed that the digitalis, when digested, or distilled, yields the following substances:

4. The leaves of the Digitalis purpurea, or fox-glove, are still more powerful than opium. It has been observed that the digitalis, when digested, or distilled, yields the following substances:

4. The leaves of the Digitalis purpurea, or fox-glove, are still more powerful than opium. It has been observed that the digitalis, when digested, or distilled, yields the following substances:

5. Contina maculatum, or hemlock.

6. Datura stramonium.

7. Ledin paliustris.

To these leaves the purgatives may be added the leaves of Digitalis purpurea, and the leaves of Nicotiana tabacum or tobacco. The list, indeed, might be easily increased; almost all the plants belonging to the natural order of Juris pos-
NATIONAL DEBT.

The principal advantages arising from national debts, and the system of credit on which they are founded, are: 1. The resource they afford in great emergencies, which gives a greater permanency to states, which in former times, for want of such occasional resources, were more liable to internal demage
ments and to foreign subjugation. 2. The equalization of taxes. If the supplies were raised within the year, and the expenses of war were considerable, every individual would be obliged, in consequence of the additional weight of his contributions, greatly to curtail his expenditure; the employment of the poor, and the consumption of the rich, would be considerably diminished; whereas, when taxes are nearly equal, in time of peace and war, the value of every species of property, of industry, and of the circulation of wealth, are maintained on as regular, steady, and uniform a footing, as the uncertainty and instability of human affairs will admit. 3. Their accumulating in the country, which would otherwise be sent out of it; and, by such means, the balance and debits have more influence in this respect than all the laws against the exportation of specie that ever were made. 4. They provide circular the property of the rich, and the amount they hold out to the aversive, prevent the accumulation of private hoards, and bring the whole money and personal property of a country. 5. They attach the people to the government; for every individual creditor is led by his own interest to support the authority on the property and existence of which the security of his property depends. The extent to which this influence is so well understood, that it is not probable the government of any country where a public debt has once existed, will ever permit it to be wholly paid off. 6. They encourage the practice of credit, and the encouragement of credit, by the facility with which individuals can lay out the surplus of their profits, without the risk of commercial bankruptcies, or the increase of expenses and small advantage which landed estates yield, and receive interest on their capital with certainty and regularity.

The disadvantages attending the system of incurring national debts, are: 1. The facility of carrying on war being much increased; while large sums can be easily borrowed, it may frequently cause wars to be protracted, which would have been much sooner brought to a conclusion, and the expense engendered in them experienced the difficulty of destroying the whole expense by taxation. 2. The value of the property of those who have lent their money to the state, depending on the interest to support indiscriminately the measure of government, whatever may be their tendency: they are interested both in practice, and virtue, under every invasion of the constitution of their country. 3. The increase of taxes to pay the interest of the debt, produces an increase in the price of all the necessaries of life, and renders it difficult for the manufacturer of a state in which this system has been carried to a great height, to maintain a successful competition with the subjects of other powers, who may be in a less embarrassed situation. 4. When a nation is engaged, both with debts, a precarious spirit of gambling is engendered, stock-jobbing, with all its train of evil consequences, necessarily arises; and a moneyed interest is erected, the sole employment of which is that of drawing every possible advantage from the wants of individuals, or the necessities of the public. 5. Public debts have a very material influence on the distribution of property. Every new loan must be procured from persons already possessing considerable wealth, and such persons will not lend their money without the expectation of making a profit by it; the increase of the debt is, therefore, to them a source of increasing additional taxes attendant upon it bears but a small portion; and if the government possesses no revenue but what is drawn from the people, whatever it pays to one description of men cannot be drawn principally from others; thus the additional income acquired by moneyed men, by taking advantage of the necessities of the state, is, in fact, a portion of the income of their less affluent fellow-citizens, raising money so fast as it circulates through the medium of the government, and which, in a much greater proportion than it increases their wealth, must render those poorer from whom it is drawn.

The national debt of Great Britain commenced in the reign of William III. The war which began in 1669 being very expensive, and the grants of parliament not supplying the necessary funds, the government,帐 first produce of particular taxes was assigned for repayment of the principal and interest of the money borrowed; large sums were also raised on life-assuratums, and annuities for terms of years; and the funds established for payment of these debts being generally inadequate to the charge upon them, occasioned great deficiency, and the war, amounted to 5,160,450l. 12s. 9d. in 1698, and was charged on the continuation of various duties which had been granted for short terms. The total amount of the funded and unfunded debts in the year 1697, was 192,094,947l. 10s. 8d. The frequent expectation of the different funds, and their general deficiency from the diminution of the revenue, in consequence of which the interest due upon the national debt to government was often long in arrear, reduced public credit at this period to a very low ebb, and rendered persons who had money very reluctant in advancing it to the government, though paid what would now be called an exorbitant interest; the accumulation of the public debts caused serious apprehensions among people of property of all descriptions.

The great expense of the war during the reign of queen Anne was chiefly defrayed by the sale of annuities for different terms, but mostly for 99 years; and money was not only borrowed to pay the interest of loans, but often to pay the deficiency of that interest; or, what is much the same thing, the arrears of interest were converted into principal, by
NATIONAL DEBT.

which means, and from great mismanagement of the public finances, the debt rapidly increased, so that at the end of the year 1727, the total of the funded debt amounted to £12,235,039, or 4.25d. of which it must be remembered that upwards of three million and a half was additional capital created by the South Sea company's subscription.

The whole sum paid off by the sinking fund from its establishment to the year 1739, was closer than £5,298,341. The total amount of the debt at this period, was £3,054,635. 3s. 4d.

The war with Spain and France, which began in the same year, increased the debt to £13,303,315. 1s. 0d., on which amount the interest of money, which had been during the war to upwards of 4 per cent. fell, together with the creation of hostilities terminated the loans of government, and the administration seized the moment of increased prosperity to propose another important reduction of interest. Towards the end of 1739, 3 per cent. stock had been for some months above par, and Parliament passed by which the interest was reduced on all the public debts redeemable by law, which then carried 4 per cent. interest, forming to a capital of £3,475,6s. 4d. The proprietors, on signifying their intention to the reduction, were to have 4 per cent. interest to the 25th December following, thence 34 per cent. till 25 December, 1757, and after- wards 3 per cent. per annum. Upwards of three millions remained unsubsisted, which was therefore paid off, by money borrowed at 3 per cent., and thus a saving of £1,735,6s. 4d. per annum was effected, which ought to have been transferred materially to the reduction of the debt. Little progress, however, was made in diminishing the capital of the debt; and at the commencement of the war in 1755 it amounted to £7,440,886l. 8s. 2d.

The great expenses of the war rendered the loans of greater magnitude than had ever before been raised, and the debts incurred were somewhat increased by the practice of entitling the persons lending the money to the same per cent. in all cases, usually advanced; so that at the end of the war, including the loan of 1763, they amounted to £14,691,631l. 13s. 4d., and the annual interest was £4,708,734l. 12d.

During the course of 12 years of peace, little was done in reality towards diminishing the amount of the debt; for although in each year from 1755 to 1775, some small portion of the funded debt was paid off, the whole amounted to only £1,983,534, being a less amount than had sometimes been borrowed in one year of war; and the debt was far from being diminished even that amount, as during the same period a new debt of £6,032,500l. was contracted, by borrowing money on 3 per cent. stock, in order to redeem 4 per cent.

The American war was entered into with a funded debt of £9,333,031l., including an estimated value of the long annuities and exchequer annuities, and an unfunded debt of about £6,300,000, making together £15,634,031l., the interest on which amounted to £642,021l. per annum. The expenses of this war greatly exceeded those which had preceded it; and the increase of the debt was much greater than had ever been incurred by any country in the same space of time. The following statements will shew the extent of the sums borrowed, and the additions thus made to the annual burthen of the country:

From which it appears that a nominal capital of £21,900,000l. was added to the sum of 75,500,000l., actually borrowed, and that the interest on the whole amounted to 5l. 9s. 1d. per cent., on which the perpetual interest was equal to 4l. 6s. per cent., on the whole sum. In addition to the above sums, a very considerable amount of navy debt was funded after the conclusion of the war, which being properly part of the expenses of it, the total debt incurred by the American war may be stated as follows:

The whole amount of the funded and unfunded debts, including a valuation of the terminable annuities, was on the 5th Jan. 1786, £268,100,379l. 18s. 6d., and the amount of the annual interest £1,312,239l. 7s. 9d.

The magnitude of the public debt, and the consequent low price of the funds, appear at this period to have engaged the serious attention of the government; in consequence of which some new taxes were imposed, in order to raise a surplus of revenue, as the formation of a navy, and for establishing a new sinking fund. In order to ascertain what per cent. of the revenue might be appropriated to this purpose, a select committee of the house of commons was appointed to examine and state the amounts presented to the house relating to the public income and expenditure, and report what might be expected to be the annual amount of the income and expenditure in future. On the 21st March, 1786, the committee made their report; and conceiving that the circumstances of the times rendered any average drawn from the amount of the revenue in former periods in a great degree inapplicable to the situation of the country, they formed an account from the receipt and expenditure to Michaelmas 1775, and from January 1786, from which it appeared, that at the former period there was a surplus of 911,000l., and at the latter a surplus of 519,000l. less than one million per annum would be very inadequate to the purpose for which it was designed, new taxes were imposed for raising the surplus revenue to this sum; and in order the more effectually to prevent the ministers from diverting it to any other purpose, the mode was adopted which had been frequently suggested, of vesting the annual sums in the hands of commissioners; some other

Since the period at which the above statement terminates, another war has been entered into, which has already added many millions to the public debt; but as the sum to which it may be increased is beyond the reach even of probable estimate, we can only give the following statement of the total amount of the Debt on the 1st January, 1803, which will also show the different descriptions of Stock and Annuities of which it consists:

NATRUM. See Soda.

NATIVITY, in old law-books, signified villainage or servitude.

NATURAL HISTORY. The object of this branch of science may be divided into two heads; the first teaches us the characteristics, or distinctive marks, of each individual object, whether animal, vegetable, or mineral; the second makes us acquainted with all its peculiarities, as to its habits, its qualities, and its uses. To assist in attaining the first, it is necessary to adopt some system of classification, in which individuals that agree in particular points may be arranged together. In this work we have adopted the Linnaean system, as the most simple and perfect that has been presented to the public.

A knowledge of the second head is only gained by a patient investigation of each particular object; for this we refer the reader to the several genera described in these volumes, under which we have endeavoured to give a brief account of all the interesting and material facts.

The study of natural history consists in the collection, arrangement, and exhibition of the various productions of the earth. These are divided into the three grand kingdoms of nature, the boundaries of which meet together in the zoophytes. See Zoophytes.

Minerals inhabit the interior parts of the earth, in rude and shapeless masses. They are bodies concrete without life and sensation. See Mineralogy.

Vegetables inhabit the surface with verdure, imbibe nourishment through bivalved roots, breathe by leaves, and continue their kind by the dispersion of seed within prescribed limits. They are organized bodies, and have life and sensation. See Botany.

Animals adorn the exterior parts of the earth, respire and generate eggs; are impelled to action by hunger, affections, and pain; and by preying on other animals and vegetables, restrain within proper bounds and proportions the numbers of both. They have organized bodies, and have life, sensation, and the power of locomotion.

Man, the governor and subjugator of all other beings, is, by his wisdom alone, able to form just conclusions from such things as present themselves to his senses, which consist of natural bodies. Hence the first step of wisdom is to know these bodies; and to be able, by marks imprinted on them by the God of nature, to distinguish them from each other, and to affix to every object its proper name. These are the elements of this science; this is the great alphabet of sciences, for if the name is lost, the knowledge of the object is lost also.

The method adopted in natural history, indicates that every body may, by inspection, be known by its peculiar name, and this points out whatever the industry of man has been able to discover concerning it; so that, whilst the greatest apparent confusion, the greatest order is science.

The Linnaean system is divided into five branches, each subordinate to the other: these are, class, order, genus, species, and variety, with their names and characters. In this arrangement, the classes and orders are arbitrary, the genera and species are natural. Of the three grand divisions above referred to, the animal kingdom ranks highest in com-
NAVIGATION, the art of conducting a ship from one point to another. The main end of all practical navigation is, to conduct the ship in safety to her destined port; and for this purpose it is necessary to know in what particular part of the surface of the globe she is at any particular time. This can only be done by having an accurate map of the sea-coasts of all the countries of the world, and, by tracing out the ship's progress along the map, to know at what time she approaches the desired haven, or by obtaining her course in order to reach it. It is therefore a matter of great importance for navigators to be furnished with maps, or charts, as they are called, not only very accurate in themselves, but such as are capable of having the ship's course easily traced upon them, without the trouble of laborious calculations, which are apt to create mistakes. The navigator should have a perfect knowledge of the figure and motion of the earth; the various real and imaginary lines upon it, so as to be able to ascertain the distance and situation of places with respect to one another. He should also be acquainted with the several instruments employed in measuring the ship's way; such as the log, half-mile glass; quadrant to take the altitude of the sun and stars; compass to represent the sensible horizon, and azimuth compass to take the azimuth and amplitude of the sun, in order to know the variation of the magnetic needle. He should have an accurate knowledge of maps and charts of the lands and seas, together with the depth of water, the times and setting in of the tides upon the coasts that he may have occasion to visit, also the currents, of the mould and trim of the ship, and the sail she bears, so as to give allowance may be made for lee-way. By the help of these, he may at all times know the place the ship is in, which way he must steer, and how far he has to run to gain his intended port.

The names of the two great divisions of navigation are taken merely from the kind of charts used. Plane sailing is that in which the plane chart is made use of; and Mercator's sailing, or globular sailing, is that in which Mercator's chart is used. In both these methods, it is easy to find the ship's place with as great exactness as the chart will allow, either by the solution of a case in plane trigonometry, or by geometrical construction.

1. Plane sailing. As a necessary preliminary to our understanding this method of navigation, we shall here give the construction of the plane chart.

1. This chart supposes the earth to be a plane, and the meridians parallel to one another; and likewise the parallels of latitude at equal distances from one another, as they really are upon the globe. Though this method is in itself evidently false; yet, in a short run, and especially near the equator, an account of the ship's way may be kept by it tolerably well.

Having determined the limits of the chart, that is, how many degrees of latitude and longitude, or meridional distance (they being in this chart the same), it is to contain: suppose from the lat. of 60° N. to the lat. of 71° N., and from the longitude of London in 0 deg. to the long. of 50° W.; then choose a scale of equal parts, by which the chart may be contained within, and write a sheet of paper on which it is intended to be drawn.

Make a parallelogram ABCD (Plane Navigation, fig. 1), the length of which A5 from north to south 90°; and suppose the difference of latitude between the limits of 50° and 71°; and the breadth AD from east to west shall contain the proposed 90° degrees of longitude, the degrees being taken from the said scale, and this parallelogram will be the boundaries of the chart.

About the boundaries of the chart make scales containing the degrees, halves, and quarters of degrees (if the scale is large enough); or drawing lines across the chart through every 5 or 10 degrees; let the degrees of latitude and longitude have their respective numbers entered, and the sheet is then fitted to receive the places intended to be delineated thereon.

On a straight slab of a cork board, or stiff paper, let the scale of the degrees and parts of degrees of longitude, in the line AD, be laid close to the edge; and the divisions numbered from the right hand towards the left, being all west longitudes.

Seek in a geographical table for the latitudes and longitudes of the places contained within the proposed limits; and let them be written out in the order in which they increase in latitude.

Then, to lay down any place, lay the edge of the paperboard scale to the divisions on each side the chart, showing the latitude of the place; so that the beginning of its divisions falls on the right-hand border AB; and against the division of the longitude of the given place make a point, and this gives the position of the place proposed; and in like manner are all the other places to be laid down.

Draw lines from one point to the other, where the coast is contiguous, and thus the representation of the lands within the proposed limits will be delineated.

Write the names to the respective parts, and in some convenient place insert a compass, and the chart will be completed.

2. The method by the meridian and rhumb that a ship sails upon, is called, as we have said, the ship's course. Thus, if a ship sails on the N.N.E. rhumb, then her course will be 22° 20'; and so of others, as is manifest from the following table of the angles which every point of the compass makes with the meridian.

3. The distance between two places lying on the same parallel counted in miles of the compass, or the distance of one place from the meridian of another counted as above on the parallel passing over that place, is called meridional distance; which, in plane sailing, goes under the name of departure.

4. Let A (fig. 5), denote a certain point on the earth's surface, AC its meridian, and AD the parallel of latitude passing through it; and suppose a ship to sail from A on the N.N.E. rhumb till she arrives at B; and through B draw the meridian BD, which, according to the principles of plane sailing, must be parallel to CA, and the parallel of latitude BC; then the length of AB, viz. how far the ship has sailed upon the N.N.E. rhumb, is called her distance; AC or BD will be her distance of latitude, or marching CB will be her departure, or easing; and the angle CAB will be the course. Hence it is plain, that the distance sailed will always be greater than either the difference of latitude or departure; it being the hypothesis of a right-angled triangle, whereas of the other two are the legs; except the ship sails either on a meridian or parallel of latitude: for if the ship sails on a meridian, then it is plain, that her distance will be just equal to her difference of latitude, and she will have no departure; but if she sails on a parallel, then her distance will be the same with her departure, and she will have no difference of latitude. It is evident also from the figure, that if the course is less than 4 points, 45 degrees, its complement, viz. the other oblique angle, will be greater than 45 degrees, and so the difference of latitude will be greater than her departure; but if the course is greater than 4 points, then the difference of latitude.
will be less than the departure; and lastly, if the course is just 90°, the difference of latitude will be equal to the departure.

5. Since the distance, difference of latitude, and departure, form a right-angled triangle, in which the side between south and west, or the departure is the course, and the other its complement; therefore, having any two of these given, we can (by plane trigonometry) find the rest, and hence arrive the cases of plane-sailing, which are as follow:

Case I. Course and distance given, to find the difference of latitude and departure.

Example. Suppose a ship sails from the latitude of 30° 25' N., to the latitude of 30° 23' N., and the course is 30°, required the difference of latitude and departure, and the latitude come to. Then by right-angled trigonometry we have the following analogy for finding the departure, viz.

\[
\text{As the distance sailed to the Departure BC} = 13.25 \times 10.00000 \\
\text{so is the sine of the course A 25° 30'} = 9.38584 \\
\text{to the departure BC 20.57} \\
\text{so the ship has made her latitude, or made of north, 28.57 minutes.}
\]

And since her former latitude was north, and her difference of latitude also north; therefore, To the latitude sailed from - 30° 23' N 20.57
add the difference of latitude 30° 25' N and the sum is the latitude come to 30°, 54.57'.

By this case are calculated the tables of difference of latitude, and departure, to every degree, point, and quarter point, of the compass.

Case II. Course and difference of latitude given, to find distance and departure.

Example. Suppose a ship in the latitude of 45° 30' N., sails NE 80° Easterly (Plate Navigation, fig. 4), till she comes to the latitude of 46° 55' N.: required the distance and departure made good upon that course.

Since all latitudes are north, and the course also northerly; therefore, From the latitude come to - 46° 55' \\
subtract the latitude sailed from - 45° 30' \\
and there remains - 1° 55' \\
the difference of latitude, equal to 10 miles.

And (by rectangular trigonometry) we have the following analogy for finding the departure BD, viz.

\[
\text{As the course AB} = 10.00000 \\
\text{is to the distance of latitude BD} = 0.23042 \\
\text{so is the tangent of course A} 80° 80' = 9.01904 \\
\text{to the departure BD 73.84} \\
\text{so the ship has got 73.84 miles to the eastward of her former meridian.}
\]

Again, for the distance AD, we have (by rectangular trigonometry) the following proportion, viz.

\[
\text{As the course AB} = 10.00000 \\
\text{is to the secant of the course A 80° 80'} = 10.11175 \\
\text{so is the dif of latitude AB} 90° 54' = 0.95829 \\
\text{to the departure AD} = 72.84 \\
\text{so the ship has sailed 72.84 miles to the north.}
\]

Case III. Difference of latitude and distance given, to find course and departure.

Example. Suppose a ship sails from the latitude of 30° 30' N., on a rhumb between north and west, 124 miles, and is found to have made of westing 86 miles; required the course steered, and the difference of latitude or northing.

In this case (by rectangular trigonometry) we have the following proportion for finding the course AB, (fig. 7), viz.

\[
\text{As the distance AD} = 124 \\
\text{so is the distance AB} = 86 \\
\text{to the size of the course A 45° 34'} = 8.9108 \\
\text{so is the distance to the ship's course north 32° 34'} = 89.35 \\
\text{or west, and WNW 4° 10' west nearly.}
\]

Then for the difference of latitude, we have (by rectangular trigonometry) the following analogy, viz.

\[
\text{As the course AB} = 10.00000 \\
\text{is to the distance AD} = 124 \\
\text{so is the diff of latitude AB} = 90° 02' \\
\text{to the course of the ship A 45° 35'} = 8.9108 \\
\text{so is the size north or west 32° 34'} = 89.35 \\
\text{which is equal to 1 degree and 39 min. nearly.}
\]

Case IV. Difference of latitude and departure given, to find course and distance.

Example. Suppose a ship in the latitude of 34° 20' N., sails ESE, till she has made of easting 90 miles; required the distance and difference of latitude made good.

In this case (by rectangular trigonometry) and by case 2, we have the following proportion for finding the distance (fig. 8), viz.

\[
\text{As the size of the course G 135° 45'} = 9.74474 \\
\text{so is to the departure HM 90} = 1.98527 \\
\text{so is radius} = 10.00000 \\
\text{to the distance GM} = 17.25 \\
\text{2.07338}
\]

Then, for the difference of latitude, we have (by rectangular trigonometry) the following analogy, viz.

\[
\text{As the tangent of course} 23° 45' = 9.92399 \\
\text{so is to the departure HM 90} = 1.98527 \\
\text{so is radius} = 10.00000 \\
\text{to the difference of lat. GH 145.7} = 2.15738 \\
\text{2.54' nearly.}
\]

Again, the latitude the ship sailed from was south, and she sailing still towards the south,

To the latitude sailed from - 23° 45' \\
add the difference of latitude 1° 20' \\
and the sum is 24° 55' N.

And the ship is the latitude she is come to south.

6. When a ship sails on several courses in 24 hours, the reducing all these into one, and thereby finding the course and distance made good upon the whole, is commonly called the reckoning of a traverse.

7. At sea they commonly begin each day's reckoning from the noon of that day, and from that time they set down all the different courses and distances sailed by the ship till noon next day upon the log-board; then from those several courses and distances, they compute the difference of latitude and departure for each course (by Case I. of Plane Sailing); and these, together with the courses and distances, are set down in a table, called the Traverse Table, which consists of five columns: in the first which are placed the courses and distances; in the two next, the differences of latitude belonging to these courses, according as they are north or south; and in the two last, the departures belonging to these courses, according as they are east or west. Then they sum up all the northings and all the southings; and taking the differences of these, they know the difference of latitude made good by the ship in the last 24 hours, which will be north or south, according as the sum of the northings or southings is greatest; the same way, by taking the sum of all the eastings, and likewise of all the westings, and subtracting the lesser of these from the greater the difference will be the departure made good by the ship last 24 hours, which will be east or west according as the sum of the eastings is greater or less than the sum of the westings; then from the difference of latitude and departure made good by the ship last 24 hours, found as above, they find the true course and distance made good upon the whole (by Case 4. of Plane Sailing) as also the course and distance to the intended port.

Example. Suppose a ship at sea, in the latitude of 45° 20' N., on any day it is found to be in a port in the latitude of 43° 50' N., whose departure from the Ll. is 114 miles east; consequently the direct course and distance of the ship is 53° 24' east, which is made good on by reason of the shifting of the winds she is obliged to steer.
the following courses; till noon next day, viz. SE 36 miles, SSE 61 miles, NWW 45 miles, NW 4 west 54 miles, and SE 4 4 east 74 miles: required the course and distance made good the last 24 hours, and the bearing and distance of the ship from the intended port.

The solution of this traverse depends entirely on the 1st and 2nd Cases of Plane Sailing; and first we must (by Case 1) find the difference of latitude and departure for each course. Thus,

1. Course SSE distance 55 miles.
   
   For departure.
   
   As radius
   
   is to the distance
   
   so is the sine of the course
   
   to the departure
   
   10.00000

   For difference of latitude.
   
   As radius
   
   is to the distance
   
   so is the sine of the course
   
   to the dif of latitude
   
   5.72413

2. Course SSE and distance 61 miles.

   For departure.
   
   As radius
   
   is to the distance
   
   so is the sine of the course
   
   to the departure
   
   10.00000

   For difference of latitude.
   
   As radius
   
   is to the distance
   
   so is the sine of the course
   
   to the dif of latitude
   
   7.13840

3. Course NW 4 west and distance 48 miles.

   For departure.
   
   As radius
   
   is to the distance
   
   so is the sine of the course
   
   to the departure
   
   10.00000

   For difference of latitude.
   
   As radius
   
   is to the distance
   
   so is the sine of the course
   
   to the dif of latitude
   
   3.82739

4. Course SE 4 4 east and distance 74 miles.

   For departure.
   
   As radius
   
   is to the distance
   
   so is the sine of the course
   
   to the departure
   
   10.00000

   For difference of latitude.
   
   As radius
   
   is to the distance
   
   so is the sine of the course
   
   to the dif of latitude
   
   8.16702

Now these several courses and distances, together with the differences of latitude and departures deduced from them, being set down in the proper columns in the traverse table, will stand as follow:

**The Traverse Table.**

<table>

Diff. of Lat. 187.91 46.97 Eps.

**NAVIGATION.**

From the above table it is plain, since the sum of the northings is 256.7, and of the southings 914.58, that the difference between those, viz. 187.91, will be the shilling made good by the ship the last 24 hours; also the sum of the castings being 155.54, and of the bearings 53.56, the difference 46.97 will be the course or departure the ship has made good by the ship's last 24 hours; consequently, to find the true course and distance, round the ship's last true post in time, it will be (by Case 4, of Plane Sailing),

As the difference of latitude 187.91 2.73936 is to the radius 10.00000
so is the departure 46.97 1.77815
to the tangent of the course 14.56° 09.39789 which is SSE 4 3 east nearly. Then for the distance, it is to be,

As radius

is to the difference of latitude 187.91 2.73936
so is the secant of the course 14.56° 10.01319
As the difference of latitude 2.73936 1.28712 consequently the ship has made good last 24 hours, on a SSE 4 east course, 193.7 miles: and since the ship is sailing towards the equator, therefore,

From the latitude sailed from - 44° 24' N take the diff of latitude made good 3° 08' 8

there remains - 41° 16' N the latitude the ship is in north. And because the port the ship is bound for lies in the latitude of 40° 00' N, and consequently south of the ship; therefore,

From the latitude the ship is in - 44° 24' N take the latitude she is bound for - 40° 20' N

is to the cosine of the lat. 10.00000
so is the departure 97 1.98677
to the tangent of the course 45.56° 19.00000

As radius

is to the difference of latitude 97.19637
so is the secant of the course 45.56° 10.13590
As the difference of latitude 1.96337 2.19690 consequently the true bearing and distance of the intended port, is SE 193.7 miles.

**Example 2.** A degree on the equator being 60 miles or nautical miles, required the length of a degree on the parallel of 57° 30'.

By Cor. 8 of the last article, it will be

10.00000 is to the cosine of the lat. 57° 30' 9.76579 so are the minutes of diff. lon. 765 2.18566 to the distance on the parallel 464.1 2.69438

Note: When the length of any parallel of latitude is required, it is the length of any parallel of latitude for the miles answering to a degree on the parallel of 57° 30'.

By this problem a table is constructed, showing the geographical answering to a degree on any parallel of latitude, from which you may observe, that the column marked at the top with D. L. contains the degrees of latitude between the equator and the parallel, and that the adjacent columns marked at the top Miles, contain the geographical miles answering to a degree upon these parallels. See the table in the article Max. Though the table does only shew the miles answering to a degree of any parallel, whose latitude consists of a whole number of degrees; yet it may be made to serve for any parallel whose latitude is some number of degrees and minutes, by making the following proportion.

As 1 degree, or 60 minutes, is to the degrees answering to a degree in the next greater and next less parallel than that proposed; so is the excess of the proposed parallel above the next parallel latitude, to a proportional part; which, subtracted from the miles answering to a degree of longitude in the next less parallel latitude, will give the miles answering to a degree in the proposed latitude.

**Example.** Required to find the miles answering to a degree on the parallel of 56° 44'.

In the next parallel of latitude in the table that than proposed, viz. that of 56°, a degree of which (by the table) is equal to 55.55 miles; and the next greater parallel of latitude in the table, than that proposed, viz. that of 57° 30', a degree of which (by the table) is equal to 39.58 miles; the difference of these is 17, and the distance between these parallels is 1 degree, or 60
NAVIGATION.

When the earth is imagined as a sphere, the distance between any two points on its surface is the shortest of all great circles. The latitude and longitude of any place are the coordinates of that place, and the difference of latitude and longitude between two places is defined by the angle between the plane of the great circle passing through the two places and the plane of the meridian at any one of the places.

Case I. The latitudes of two places, and their difference of longitude given, to find the direct course and distance.

Example. Required the direct course and distance between the Lizard in the latitude of 50° 00' N, and longitude of 4° 14', west, and St. Vincent in the latitude of 17° 10' N, and longitude of 29° 20' W. First, To the latitude of the Lizard 50° 00' N add the latitude of St. Vincent = 17° 10' = 23° 10'. The cosine of the middle parallel 33 33 N = 0.99909. To the same, the cosine of the same parallel 9.86924. To the difference of the same parallel 2.98557. And for that course it will be (by Case 4. of Plane Sailing) = 289° 37' 5.6838 W. miles.

Case II. Sailing. Given the course and distance, to find the latitude and longitude of the place of arrival.

Example. A ship sails on a certain parallel of latitude 50° 00' N. What will be its latitude and longitude when it is 10° 00' W. distant from that place? As already explained, the cosine of the middle parallel between the two places is given by the cosine of the middle parallel of St. Vincent, and the cosine of the middle parallel of the place of arrival, divided by their difference, will give the cosine of the middle parallel of the course sailed. When this is multiplied by 180°, it will give the difference of latitude and longitude of the place of arrival. Then, suppose a ship sails on a certain parallel of latitude 50° 00' N, and is 10° 00' W. distant from that place. The latitude and longitude of the place of arrival will be 40° 00' N, and 60° 00' E. respectively.

Case III. Course and difference of latitude and longitude given; to find the distance sailed and difference of longitude.

Example. Suppose a ship in the latitude of 50° 00' N, sails 50° 00' W. till she has arrived at the latitude of 50° 00' N, and 3° 00' W., and has sailed a distance of 10° 00'. Then, to find the distance sailed and difference of longitude, subtract the distance sailed from the distance between the two places by sight, and divide by the cosine of the middle parallel, which will give the cosine of the difference of longitude of the place of arrival. Then, multiply that cosine by 180°, and divide by the number of minutes in the degree, and you will have the difference of longitude of the place of arrival. When this is subtracted from the difference of longitude of the course, the result will give the difference of longitude of the place of arrival. Then, by the difference of longitude of the place of arrival, and the difference of latitude of the same place, multiply the cosine of the difference of longitude of the place of arrival by the cosine of the middle parallel of the place of arrival, and divide by the cosine of the difference of longitude of the course sailed. When this is multiplied by 180°, it will give the difference of latitude of the place of arrival. Then, by the difference of latitude of the place of arrival, and the difference of longitude of the same place, subtract the difference of latitude of the place of arrival from the difference of longitude of the course sailed, and divide by the cosine of the middle parallel of the place of arrival. When this is multiplied by 180°, it will give the difference of longitude of the place of arrival.

Case IV. Difference of latitude and longitude, given; to find the course and distance of the voyage.

Example. Suppose a ship in the latitude of 50° 00' N, sails 50° 00' W. till she has arrived at the latitude of 50° 00' N, and 3° 00' W., and has sailed a distance of 10° 00'. Then, by the difference of longitude of the place of arrival, and the difference of latitude of the same place, multiply the cosine of the difference of longitude of the place of arrival by the cosine of the middle parallel of the place of arrival, and divide by the cosine of the difference of longitude of the course sailed. When this is multiplied by 180°, it will give the difference of latitude of the place of arrival. Then, by the difference of latitude of the place of arrival, and the difference of longitude of the same place, subtract the difference of latitude of the place of arrival from the difference of longitude of the course sailed, and divide by the cosine of the middle parallel of the place of arrival. When this is multiplied by 180°, it will give the difference of longitude of the place of arrival.

Case V. Given the course and distance, to find the latitude and longitude of the place of arrival.

Example. A ship sails on a certain parallel of latitude 50° 00' N, west 200° 00' W. till she has arrived at the latitude of 50° 00' N, and 3° 00' W., and has sailed a distance of 10° 00'. Then, by the difference of longitude of the place of arrival, and the difference of latitude of the same place, multiply the cosine of the difference of longitude of the place of arrival by the cosine of the middle parallel of the place of arrival, and divide by the cosine of the difference of longitude of the course sailed. When this is multiplied by 180°, it will give the difference of latitude of the place of arrival. Then, by the difference of latitude of the place of arrival, and the difference of longitude of the same place, subtract the difference of latitude of the place of arrival from the difference of longitude of the course sailed, and divide by the cosine of the middle parallel of the place of arrival. When this is multiplied by 180°, it will give the difference of longitude of the place of arrival.

Therefore, the latitude and longitude of the place of arrival will be 40° 00' N, and 60° 00' E. respectively.
NAVIGATION.

equal to 4° 39', the difference of longitude 

Case V. Course and departure given; to find 
the difference of latitude, difference of longitude, and 
distance sailed.

Example. Suppose a ship in the latitude 

of 48° 23' north, sails 235 miles, till she has made 

of westing 193 miles: required the latitude come 
to, the difference of longitude, and the distance 
sailed.

First, For the distance, it will be, (by Case 6. 
of Plane Sailing).
As the sine of the course 32°, 43' 6.74174
is to the departure 123 2.08991
so is radius 10.00000

to the distance 231.1 2.34517
And for the difference of latitude, it will be, 
by the same Case,
As the tang. of course 28°, 43' 9.82489
is to the departure 123 2.08991
so is radius 10.00000

to the diff. of latitude 184 2.28592

equal to 3° 04', and since the ship is sailing to 

wards the equator, the latitude come to will be 

3° 19' north; and consequently the middle 

Paral will be 48° 23'.

Then, to find the difference of longitude, it will be, (Case 2. of Parallel Sailing).
As the course of the mid. par. 48° 23'
is to the departure 123 2.08991
so is radius 10.00000

to min. of diff. of longitude 180 2.28592
which is equal to 3° 04', the difference of longi 
dute westerly.

Case VI. Difference of latitude and departure 
given; to find course, distance, and difference of 
longitude.

Example. Suppose a ship in a latitude of 

48° 27' north, sails between south and east, till 
she has made of easting 146 miles, and is 
then found to be in the latitude of 48° 24' north: required the course, distance, and 
difference of longitude.

First, By Case 4. of Plane Sailing, it will be 

do the course, 193 2.28536
As the diff. of latitude 184 2.28592

so is the departure 123 2.08991

so is radius 10.00000

to the tang. of the course 38° 55' 5.87581

which, because the ship is sailing between 
south and east, will be south 30° 55' east, or SSE ½ 

east nearly.

For the distance, it will be, by the same Case,
As radius 10.00000

is to the diff. of latitude 193 2.28536
so is the secant of the course 36° 55' 10.09718

to the tangent 294 4.26897

Then, for the difference of longitude, it will be, 
by Case 2. of Parallel Sailing,
As the course of the mid. par. 43° 09' 9.84949
is to the departure 146 2.16137
so is radius 10.00000

so is the tangent of the course 30° 29' 9.7601

which, because it is between south and east, 

will be south 30° 29' west, or SSW ¼ west nearly.

And for the distance, it will be, by the same 

Case,
As radius 10.00000

is to the difference of lat. 214 2.28501
so is the secant of the course 30° 29' 10.04461

so is the tangent of the course 30° 29' 9.7601

which, because it is between south and east, 

will be south 30° 29' west, or SSW ¼ west nearly.

Example. Suppose a ship in the latitude of 

48° 27' north, sails upon the following course, 

viz. SW 63 miles, SSW 4 west 43 miles, SSE 54 
miles, and SW 74 miles: required the latitude 

the ship has come to, and how far she has 

First, By Case 2. of this sect, find the 
difference of latitude and difference of longitude 
belonging to each course and distance, and they 
will stand in the following table:

<table>
<thead>
<tr>
<th>Course</th>
<th>Distance</th>
<th>Diff. of Lat.</th>
<th>Diff. of Long.</th>

</tbody>
</table>

Diff. of Long. 143.80

Hence it is plain the ship has differed her latitude 185.2 minutes, or 3° 6', and has 

come to the latitude of 48° 19' north and has 
differed in difference of longitude 143.8 minutes, 
or 2° 24' 5", which is very strictly true; and it serves, 

without any considerable error, in running of 

450 miles between the equator and parallel of 

300 miles, of 300 miles between that and the parallel of 600 degrees, and of 150 miles 

as far as there is any occasion, and conse 

sequently must be sufficiently exact for 24 

hours run.

Of Mercator's sailing. Though the 

meridians do all meet at the pole, and the 

parallels to the equator do continually 

change, and that in proportion to the co-sines of 

their latitudes; yet in old sea-charts the meridians 

were drawn parallel to one another, and conse 

sequently the parallels of latitude made equal 

distances from one another, and so a degree of longitude 

on any parallel as large as any degree on the 

equator; also in these charts the degrees of latitude 

were still represented (as they are in 

themselves) equal to each other, and to 

those meridians which they intersected. By these means the degrees 

of longitude being increased beyond their 

true, and the more so the nearer they approach the pole, the degrees of latitude 

at the same time remaining the same, it 

is evident that on these charts with respect 

to their latitude and longitude, and conse 

quently their bearing from one another very 

false.

To remedy this inconvenience, so as still to 

keep the meridians parallel, it is plain we 

must protract, or lengthen, the degrees of latitude 

in the same proportion as those of longitude 

are, so that the proportion in east 

ing and westing may be the same with 

that in running and standing. For 

example, if the bearing on the chart 

be N 40° 20' E, which is the 

same as 40° 20' of the equator, 

and the meridian, from which draw BP 

perpendicular to AC, and BG perpendicular to CD: then 

BG will be the sine, and BF or CG the 

co-sine of BD the latitude of the point B; DB 

the tangent and CE the secant of the art 

CD. It has been demonstrated, that any 

arch of a parallel is to the like arch of the 

equator, as the co-sine of the latitude of that 

parallel to radius. Thus any arch, as a 

minute on the parallel described from the point 

B, will be to a minute on the equator, as BF 

or CG is to CD: but since the triangles CGB, 

CD, are similar, therefore CG will be 

to CD as CE to CB, i.e. the co-sine of any 

parallel is to radius as radius is to the 

secant of the latitude of that parallel. But it 

has been just now shown, that the co-sine of any 

parallel is to radius, as the length of any arch 

(as a minute) on that parallel is to the length 

of the like arch on the equator, and therefore the length of any arch (as a minute) on any 

parallel, is to the length of the like arch on 

the equator, as radius is to the secant of 

the latitude of that parallel; and so the length 

230
of any arc (as a minute) on the equator, is
longer than the like arc of any parallel, in the same proportion as the secant of the latitude of that parallel is to radius. But since in this projection the meridians are parallel, and cannot be united in one line, except parallel to the equator, no such problem can be propounded. Thus, to find the length of any arc (as a minute) on any parallel, is increased beyond its just proportion, at such rate as the secant of the latitude of that parallel is greater than radius, and therefore, to keep up the proportion of making and working to that of eating and working, upon this chart, as it is upon the globe itself, the length of a minute upon the meridian at any parallel must also be increased beyond its just proportion at the same rate, i.e., as the secant of the latitude of that parallel is greater than radius. Thus to find the length on a minute upon the meridian at the latitude of 75 degrees, since a minute of a meridian is every where equal on the globe, and also equal to a minute upon the equator, let it be represented by unity; then making it as radius to the secant of 75 degrees, so is unity to a fourth number nearly; and therefore, by whatever line you represent one minute on the equator of this chart, the length of one minute on the enlarged meridian at the latitude of 75 degrees, or the distance between the parallel of 75° 01' and that of 60° 01', will be equal to 3 of these lines, and \( \frac{3}{4} \) of one of them. By making the same proportion, it will be found that the length of a minute on the meridian of this chart at the parallel of 0° 00', will be equal to the distance of the parallel of 0° 00' and that of 75° 01', equal to two of these lines. After the same manner, the length of a minute on the enlarged meridian may be found at any latitude; and consequently be printed at the equator, and computing the length of every intermediate minute between that and any parallel, the sum of all these shall be the length of a meridian intercepted between the equator and that parallel; and the length of any parallel of latitude from the equator upon the meridian of this chart, computed in minutes of the equator, forms what is commonly called a table of meridional parts.

1. If the part of the meridian (20 00') represents the latitude of any point B, then (CD) being radius) CE will be the secant of that latitude; but it has been shown above, that radius is to secant of any latitude, as the length of a minute upon the equator is to the length of a minute upon the meridian of this chart at that latitude; therefore CD is CE, as the length of a minute on the equator is to the length of a minute upon the meridian of that chart at that latitude; therefore CD is CE, as the length of a minute on the equator is to the length of a minute upon the meridian of that chart at that latitude; therefore CD is CE, as the length of a minute on the equator is to the length of a minute upon the meridian of that chart at that latitude; therefore CD is CE, as the length of a minute on the equator is to the length of a minute upon the meridian of that chart at that latitude;...
NAVIGATION.

1. As radius
   - is the distance
   - to the course of the course $35^\circ 4^\prime$ 9.83978
to the distance of lat. $25^\circ 22'$ 2.39099
equal to $2^\circ 07'$ since the ship is sailing from a north latitude towards the south, therefore, the latitude taken will be $47^\circ 55'$ north. Hence the meridional difference of latitude will be 195.4.

2. Produce BK to D, till BD is equal to the course of the line $25^\circ 40'$ 2.21484
   so is the course of the line $25^\circ 40'$ 9.9628
   which, because the ship is sailing between north and east, will be north $35^\circ 22'$ east, or NEN $2^\circ 07'$ easterly.

Then, for the difference of longitude, it will be, (by rectangular trigonometry)

R : AC :: T : A : GB

i.e. As the proper diff. of lat. 170 2.20683
   to the course of the course $25^\circ 22'$ 9.84289
   2.27048 10.00000
   equal to $2^\circ 18'$ 48" the difference of longitude
   the ship has made westerly.

Case IV. Given course and both latitudes, viz. the latitude sailed from, and the latitude come to; to find the distance sailed, and the difference of longitude.

Example. Suppose a ship in the latitude of $56^\circ 54'$ north, sails south $3^\circ 45'$ east, until by observation she is found to be in the latitude of $51^\circ 45'$ north; required the distance sailed, and the difference of longitude.

Through A draw AB (fig. 14), to represent the meridian of the ship in the first latitude; and set off from A to B 1.53 the minutes of the proper difference of latitudes, also AG equal to 0.3, the minutes of the enlarged difference of latitude. Through B and G, draw the lines BC and GK perpendicular to AG; and also AK, making with AG an angle of $3^\circ 45'$, which will pass the two former lines in the points C and K; so the course is constructed, and AC and GK may be found from the line of equal parts.

By Calculation:

First, for the difference of longitude, it will be, (by rectangular trigonometry)

R : AC :: T : A : GB

i.e. As radius
   - is the enlarged diff. of lat. 237.2 2.1141
   to the course of the course $35^\circ 4^\prime$ 9.84289
   so is the course of the course $35^\circ 4^\prime$ 9.3407
   2.27048 10.00000
   equal to $2^\circ 18'$ 48" the difference of longitude
   the ship has made easterly.

There might also have been found, by first finding the departure BC (by Case 2, of Plane Sailing), and then it would be AB : BC : : AC : GK, the difference of longitude the ship has made easterly.

Example. Suppose a ship from the latitude of $36^\circ 35'$ N. sails between south and west, till she has made of departure 196.4 miles, and then by observation she is found to be in the latitude of $33^\circ 55'$ north; required the course and distance sailed, and difference of longitude.

Geometrically. 1. Draw AE (fig 16), to represent the meridian of the ship in the first latitude, and make the angle EAC equal to $35^\circ 4^\prime$, the angle of the course; then draw FC parallel to AE, at the distance of 196.4 the minutes of difference of longitude, which will meet AC in the point C. From C let fall upon AE the perpendicular AG, which will be the enlarged difference of latitude. To find which, by calculation, it will be, (by rectangular trigonometry)

R : AC :: T : A : GC

i.e. As the course of the course $35^\circ 4^\prime$ 9.84289
   so is the course of the course $35^\circ 4^\prime$ 9.3407
   2.27048 10.00000
   equal to $2^\circ 18'$ 48" the difference of longitude
   the ship took the merit, difference of latitude 237.2

and there remains - - - - 32.92 - the meridional parts of the latitude come to, viz. $46^\circ 09'$.

Hence, for the proper difference of latitude, from the latitude sailed from - - - - 2.35200 N. take the latitude come to - - - - 16 46 00 N.

and there remains - - - - 2.41 equal to 161, the minutes of difference of latitude.

2. Set off upon AE the length AD equal to 161 the proper difference of latitude, and through D draw DB parallel to CE; then AB will be the direct distance. To find which, by calculation, it will be, (by rectangular trigonometry)

R : AD :: T : A : DB

i.e. As radius
   - is the proper diff. of lat. 155 2.10003
   to the course of the course $35^\circ 4^\prime$ 10.00000
   so is the course of the course $35^\circ 4^\prime$ 10.00000
   2.27048 10.00000
   consequently the ship has sailed south $35^\circ 4^\prime$ east 10.00000 miles, and has diminished her longitude $2^\circ 52'$ 18" easterly.

Case V. Both latitudes and distances sailed, given; to find the direct course, and difference of longitude.

Example. Suppose a ship from the latitude of $35^\circ 25'$ sails between north and east 10.3 miles, and then by observation she is found to be in the latitude of $48^\circ 6'$ north; required the direct course, and difference of longitude.

Geometrically. 1. Draw AE (fig. 16), equal to 100, the proper difference of latitude, and from the point B raise the perpendicular BD; then take 100 in your compasses, and setting down the parts of AB, draw the line BE in B. Produce AB till AC is equal to 235.6 the enlarged difference of latitude.
NAVIGATION.

which, because the ship sails between south and west, will be south 37° 27' west, or SW 06° 39' westerly.

Lastly, for the distance AB, it will be, by (rectangular trigonometry).

\[ S = a \times \sin B \quad \text{and} \quad R = \frac{a}{\tan B} \]

\[ A \times \sin B = 37.5995 \quad \text{to the departure} = 135.4 \quad 2.0175 \quad \text{it is radius} \]

\[ = 100.0000 \quad \text{to the direct distance} = 207.9 \quad 2.3170 \]

CASE IX. One latitude, distance sailed, and departure, given; to find the other latitude, difference of longitude, and course.

Example. Suppose a ship in the latitude of 48° 28' north, sails between south and east 38 miles, and has then made of departure 112° 8' required the latitude come to, the direct course, and difference of longitude.

Geometrically. I. Draw BD (fig. 19) for the meridian of the ship at B; and parallel to it draw FE, at the distance of 112° 8' the departure. Take DB, the distance in your compasses, and fixing one point of them in B, with the other cross the line FE in the point E; then join B and E, and from E draw BE perpendicular to BD the proper difference of latitude, and the angle B will be the course; to find which by calculation.

First, For the course it will be, by (rectangular trigonometry).

\[ BE \times \sin E = \text{the course} \]

\[ BE \times \cos E = \text{the angle} \]

= 2.13988

\[ = 100,0000 \]

so is the distance = 138.2 13998

so is the course of the course = 54° 41' 9.62000

so to the difference of latitude = 79.3 1.00180

= equal to 17° 19'. Consequently the ship has come to the latitude of 47° 19'. Hence the meridional difference will be 1177.

2dly. Produce B to A, till BA is equal to 117.7; and through A draw AC parallel to DE, meeting BE produced in C; then AC will be the difference of longitude; to find which by calculation, it will be found.

\[ BD \times DE = BA \times AC \]

\[ = 1000000 \]

\[ = 138.2 13998 \]

\[ = 54° 41' 9.62000 \]

\[ = 79.3 1.00180 \]

\[ = 17° 19' \]

Hence G being the middle parallel of the chart, and the point in the west, the course BA will be 11° 19', which is the difference of longitude to the parallel of the chart.

Having shown under the article Maps how to construct a Mercator's chart, we shall now proceed to point out its several uses.

Prob. I. Let it be required to lay down a place upon the chart, its latitude, and the difference of longitude between it and some known place upon the chart being given.

Example. Let the known place be the Lizard, lying on the parallel of 30° 00' north, the place to be laid down St. Katherine's on the east coast of America, differing in longitude from the Lizard 42° 39', lying so much to the westward of it.

Let L represent the Lizard on the chart, (fig. 20) lying on the parallel of 50° 00' north, its meridian. Set off AB from E upon the equator EQ 42° 39', towards Q, which will reach from E to T; and this will be the meridian of St. Katherine's then set off from Q to H upon the graduated meridian OB, 38 degrees, and through H draw the parallel of latitude HI, which will meet the former meridian in K, the place upon the chart required.

Prob. II. Given two places upon the chart; to find their difference of latitude and difference of longitude.

Through the two places draw parallels of latitude; then the distance between these parallels, numbered in degrees and minutes upon the graduated meridian, will be the difference of latitude required; and through the two places drawing meridians, the distance between these, counted in degrees and minutes on the equator, or any parallel graduated, will be the difference of longitude required.

Prob. III. To find the bearing of one place from another, upon the chart.

Example. Required the bearing of St. Katherine's at K, from the Lizard at L.

To find the meridian of the Lizard AE, and join K and L with the right line KL; then, by the line of chords, measuring the angle KLE, and with that entering the tables, we shall have the thing required.

This may also be done, by having compasses drawn on the chart (suppose at two of its corners); then lay the edge of a ruler over the two points, and let fall a parallel that take the nearest distance from the centre of the compass next the first place, to the ruler's edge; then, with this distance in your compasses, slide them to the other place, draw them as near to the one close to the ruler, and the other as near as you can judge perpendicular to it, which will describe the rhumb required.

Prob. IV. To find the distance between two given places upon the chart.

This problem admits of four cases, according to the situation of the two places with respect to one another.

Case I. When the given places lie both upon the equator.

In this case their distance is found by converting the degrees of difference of longitude intercepted between them into minutes.

Case II. When the two places lie both on the same meridian.

Draw the parallels of those places; and the degrees upon the graduated meridian, intercepted between those parallels, reduced to minutes, give the distance required.

Case III. When the two places lie upon the same parallel.

Example. Required to find the distance between the points K and N, both lying on the parallel of 50° 00' north. Take from your scale 119° 5' to e: through the parallel of the point K plotted on the chart, and with that extent on KN as a base make the isosceles triangle KPN: then take from the line of sines the co-sine of the latitude, or sine of 72° and set that off from P to S and T. Join S and T with the right line ST, and that applied to the graduated equator will give the degrees and minutes upon it equal to the distance; which, converted into minutes, will be the distance required.

The reason of this is evident from the method of Parallel Sailing; for it has been there demonstrated, that radius is to the co-sine of any parallel, as the length of any arc on the circumference, to the length of the same arc on that parallel. Now, in the isosceles triangle KPN is the distance of the meridians of the two places K and N upon the equator; and since, in the triangle LPT is parallel to KN, therefore PT = PT = PT = PT = PT = TS. Consequently TS will be the distance of the two places K and N upon the parallel of 50° 00'.

If the parallels the two places lie on is not far from the equator, and they not far asunder, then their distance may be found thus: Take the distance between them in your compasses and apply that to the graduated meridian, so that one foot may be as many miles above as the other is below the given parallel; and the degrees and minutes intercepted, reduced to minutes, will give the distance.

Or it may also be found thus: Take the length of a degree on the meridian at the given parallel, and turn that over on the parallel from the one place to the other, as off as you can; then take that distance as far as you can go on the chart before you run over the other places, so many times 60 miles will be contained in the distance between them.

Case IV. When the places differ both in longitude and latitude.

Example. Suppose it was required to find the distance between the two places a and b upon the chart. By Prob. II, find the difference of latitude between them; and take that in your compasses from the graduated equator, which set off on the meridian of 60° a, from a to k; then through draw ke parallel to de; and taking ac in your compasses, apply it to the graduated equator, and it will shew the degrees and minutes contained in the distance required, which multiplied by 60 will give you the miles of distance.

The reason of this is evident; for it is plain that the difference of longitude makes the apparent difference of latitude in the space that you have passed over the chart being known, and the space that you have run over the chart having the course and difference of latitude that a ship has made, to lay down the running of the ship, and find her place upon the chart.

Example. A ship from the Lizard in the latitude of 50° 00' north, sails SSW till she has differed her latitude 50° 40'; required her place upon the chart.

Count from the Lizard at L, on the graduated meridian downwards (because the course is southerly) 50° 40' to g; through which draw a parallel of latitude, which will be the parallel the ship is in; then from L draw a SSW line k, cutting the former parallel in f, and this will be the ship's place upon the chart.

Prob. VI. One latitude, course, and distance sailed, given; to lay down the running of the ship, and find her place upon the chart.

Example. Suppose a ship a in the latitude of 30° 00' north, sails north 37° 20', east 191 miles; required the ship's place upon the chart.

Having drawn the meridian and parallel of the place a, set off the rhumb line ae, making with as an angle of 37° 20'; and upon it set off 191 miles; through that point parallel to ae, and taking sb in your compasses, apply it to the graduated equator, and observe the number of degrees it contains; then count the same number of degrees on the graduated meridian from C to c, and through draw the parallel of course, which will cut sb produced in the point c, the ship's place required.

Prob. VII. Both latitudes and distance sailed, given; to find the ship's place upon the chart.

Example. Suppose a ship sails from a, in the latitude of 20° 00' north, between north and east 191 miles, and is then in the latitude of 45° 00' north. Required the ship's place upon the chart.

Draw sb the parallel of 45°, and set off upon the meridian of a upwards, sb equal to the proper difference of latitude between the equator or graduated parallel. Through sb parallel to de; then, with 191 in your compasses, fixing one foot of them in a, with the other 191 feet in c; joining a c, which produced would meet de in d, the ship's place required.

Prob. VIII. One latitude, course, and difference of longitude, given; to find the ship's place upon the chart.
Example. Suppose a ship from the Lizard in the latitude of 30° 00' north, sails SW 20°, till her difference of longitude is 42° 20'; she required the ship's place upon the chart.

Having drawn the meridian of the Lizard at A, count from E to F upon the equator 42° 30'; and through F draw the meridian EF; then from L draw the SW 20° line LF, and where this meets EF, as at L, will be the ship's place required.

Problem I. One latitude, course, and departure; given; to find the ship's place upon the chart.

Example. Suppose a ship at a in the latitude of 30° 00' north, sails north 20° east, till she has made of departure 116 miles; required the ship's place upon the chart.

Having drawn the meridian and parallel of the place a, set off upon the parallel as equal to 116, and through a draw the meridian B. Take the given distance 116 in your compasses, and set off from a to the parallel B, then you will find the ship's place to be b.

Problem X. One latitude, distance, and departure; given; to find the ship's place upon the chart.

Example. Suppose a ship at a in the latitude of 20° 00' north, sails 191 miles between north and east, till she is then found to have made of departure 116 miles; required the ship's place upon the chart.

Having drawn the meridian and parallel of the place a, set off upon the parallel as equal to 116, and through a draw the meridian B. Take the given distance 116 in your compasses, and set off from a to the parallel B, and you will find the ship's place to be b.

Problem XI. The latitude sailed from, difference of latitude, and departure; given; to find the ship's place upon the chart.

Example. Suppose a ship from a in the latitude of 20° 00' north, sails between north and east, till she is found to have made of departure 116 miles; required the ship's place upon the chart.

Having drawn the meridian of a, set off upon the parallel as equal to 116, and through a draw the meridian B. Take the given distance 116 in your compasses, and set off from a to the parallel B, and you will find the ship's place to be b.

Example. Suppose a ship from the Lizard in the latitude of 30° 00' north, sails SW 20°, till her difference of longitude is 42° 20'; she required the ship's place upon the chart.

Having drawn the meridian of the Lizard at A, count from E to F upon the equator 42° 30'; and through F draw the meridian EF; then from L draw the SW 20° line LF, and where this meets EF, as at L, will be the ship's place required.

Example. Suppose a ship at a in the latitude of 30° 00' north, sails north 20° east, till she has made of departure 116 miles; required the ship's place upon the chart.

Having drawn the meridian and parallel of the place a, set off upon the parallel as equal to 116, and through a draw the meridian B. Take the given distance 116 in your compasses, and set off from a to the parallel B, then you will find the ship's place to be b.
NAVIGATION.

Making it, as 50 feet are to 41 feet, so are 6.5 knots to 5.72 knots, I find that the true rate of sailing is 5.72 miles an hour.

Again, measuring the distance between knot and knot on the log-line to be exactly 50 feet, but that the glass is not 30 seconds; then, if the glass requires longer time than 30 seconds, the distance given will be too great, if estimated by lowering one mile for every knot run in the time the glass runs; and, on the contrary, if the glass requires less time to run than 30 seconds, it will give the distance sailed too small. Consequently, to find the true distance in either case, we must measure the time the glass requires to run out (by the method in the following article); then we have the following proportion, viz.

As the number of seconds the glass runs, is to half a minute, or 30 seconds; so is the distance given by the log, to the true distance.

Example I. Suppose a ship runs at the rate of 74 knots in the time the glass runs; but measuring the glass, I find it runs 34 seconds; required the true distance sailed.

Example II. Suppose a ship runs at the rate of 63 knots; but measuring the glass, I find it runs only 25 seconds; required the true rate of sailing.

Make it, as 25 seconds are to 30 seconds, so are 6.5 knots to 7.8 knots; I find that the true rate of sailing is 7.8 miles an hour.

In order to know how many seconds the glass runs, you may try it by a watch or clock that vibrates second; but if neither of these is at hand, then take a line, and to the end fasten a plummet, hang the other upon a nail or peg so that the distance from the peg to the centre of the plummet is 30 inches: then put this into motion will vibrate seconds; r. e. every time it passes the perpendicular, you are to count one second; consequently, by observing the number of vibrations that it makes during the time the glass is running, we know how many seconds the glass runs.

If there is an error both in the log-line and half-minute glass, viz. the distance between knot and knot and the log-line is either greater or less than 50 feet, and the glass runs either more or less than 30 seconds; then finding out the ship's true distance will be somewhat more complcated, and admit of various cases, viz.

Case I. If the glass runs more than 30 seconds, and the distance between knot and knot is less than 50 feet, then the distance given by the log-line, viz. by allowing 1 mile for each knot the ship sails while the glass is running, will always be greater than the true distance, since either of these errors gives the distance too great. Consequently, to find the true rate of sailing in this case, we must first find the distance or the opposition on which the log-line only is wrong; and then with this we shall find the true distance.

Example I. Suppose a ship is found to run at the rate of 6 knots; but examining the glass, I find it runs 35 seconds; and measuring the log-line, I find the distance between knot and knot to be but 46 feet: required the true distance run.

First, we have the following proportion, viz. As 50 feet : 46 ; 6 knots : 5.52 knots.

Then, As 35 seconds: 30 seconds :: 5.52 knots: 4.73 knots. Consequently the true rate of sailing is 4.73 miles an hour.

Case II. If the glass is less than 30 seconds, and the space between knot and knot is more than 50 feet, then the distance given by the log-line will always be less than the true distance, since either of these errors lessens that true distance.

Example. Suppose a ship is found to run at the rate of 7 knots; but examining the glass, I find it runs only 25 seconds; and measuring the space between knot and knot on the log-line, I find it is 54 feet: required the true rate of sailing.

First, As 25 seconds: 30 seconds :: 7 knots : 8 knots. Then, As 50 feet : 54 feet :: 8 knots : 9.072 knots. Consequently the true rate of sailing is 9.072 miles an hour.

Case III. If the glass runs more than 30 seconds, and the space between knot and knot is greater than 50 feet; or if the glass runs less than 30 seconds, and the space between knot and knot is less than 50 feet: then, since in either of these two cases the effects of the errors are contrary, it is plain the distance will sometimes be too great, and sometimes too little, according as the greater quantity of the error line on the log-line will be evident from the following examples:

Example I. Suppose a ship is found to run at the rate of 94 knots per glass; but examining the glass, it is found to run 30 seconds; and by measuring the space between knot and knot, it is found to be 38 feet; required the true rate of sailing.

First, As 50 feet : 58 feet :: 9.5 knots : 11.20 knots. Then, As 38 seconds : 30 seconds :: 11.02 knots : 8.7 knots. Consequently the ship's true rate of sailing is 8.7 miles an hour.

Example II. Suppose a ship runs at the rate of 60 knots per glass; but examining the glass, it is found to run only 20 seconds; and by measuring the space between knot and knot, it is found to be 38 feet: required the true rate of sailing.

First, As 50 feet : 38 feet :: 4.56 knots : 9.5 knots. Then, As 20 seconds : 30 seconds :: 4.56 knots : 6.84 knots. Consequently the true rate of sailing is 6.84 miles an hour.

But if in this case it happens, that the time the glass takes to run, is to the distance between knot and knot, as 30, the seconds in half a minute, is to 50, the true distance between knot and knot; then it is plain, that whatever number of seconds the glass consists of, and whatever number of feet is contained between knot and knot, yet the distance given by the log-line will be the true distance in miles.

The meridian and the horizontal, or any plane through the horizon in four points, at 90 degrees distance from one another, viz. North South, East, and West; that part of the meridian which extends itself from the place of the north point of the horizon is called the north line; that which tends to the south point of the horizon is called the south line; and that part of the prime vertical which extends toward the right hand of the observer, when his head is turned toward the west line, is called the east line, and lastly, that part of the prime vertical which tends toward the left hand is called the west line; the four points in which these lines meet the horizon are called the cardinal points.

In order to determine the course of the wind and to discover the various alterations or shifting, each quadrant of the horizon, intercepted between the meridian and prime vertical, is usually divided into eight equal parts, and consequently the whole horizon into thirty-two; and the lines drawn from the place on which the observer stands, to the points of division in his horizon, are called rhumb-lines; the four principal of which are those described in the preceding paragraph, each of them having its name from the cardinal point in the horizon towards which it tends: the rest of the rhumb-lines have their names compounded of the principal lines on each side of them, as in the figure; and over withiows of these lines the course of the wind is directed, that wind takes its name accordingly. See Magnetism.

Hence it follows, that all rhumbs, except the four cardinlls, must be curves or hemispherical lines, always tending towards the pole, and approaching it by infinite gyration, or turnings, but never falling into it. Thus let P, F, E, and G be the arch of the equator, PF, PA, &c. meridians, and EFGIKL any rhumb; then because the angles PEF, PFG, &c. are by the nature of the rhumb-line equal, it is evident that it will form a curve-line only if we always approach the pole P, but never falling into it; for if we were possible for it to fall into the pole, then it would follow, that the same line could in an infinite number of other lines at equal angles, in the same point, which is absurd.

Because there are 32 rhumbs or points in the compass equally distant from one another, therefore the angle contained between any two of them adjacent will be 11° 15', viz. 70 of 360°; and so the angle contained between the meridian and the NNE will be 11° 15', and between the meridian and the WNW will be 23° 30'; and so of the rest. See Table of the angles &c. at the beginning of the article.

Concerning currents, and how to make proper allowances. I. Currents at certain settings of the stream, by which all bodics (as ships, &c.) moving therein, are compelled to alter their course or velocity, or both; and submit to the motion impressed upon them by the current.

Case I. If the current sets just the course of the ship, i.e. moves on the same rhumb with it; then the motion of the ship is increased, by as much as is the drift or velocity of the current.

Example. Suppose a ship sails SE&S at the rate of 6 miles an hour, in a current that sets SE&S 2 miles an hour; required her true true rate of sailing.

Here it is evident that the ship's true rate of sailing will be 8 miles an hour.

Case II. If the current sets directly against the ship's course, then the motion of the ship is lessened by as much as is the velocity of the current.

Example. Suppose a ship sails SSW at the rate of 10 miles an hour, in a current that sets NNE 6 miles an hour, required the ship's true rate of sailing.

Here it is evident, that the ship's true rate of sailing will be 4 miles an hour. Hence it is plain,
1. If the velocity of the current is less than the velocity of the ship, then the ship will get so much ahead as is the difference of velocity.

2. If the velocity of the current is greater than that of the ship, then the ship will fall so much astern as is the difference of velocities.

3. Lastly, if the velocity of the current is equal to that of the ship, then the ship will stand still, the one velocity destroying the other.

Case III. If the current thwarts the course of the ship, then it not only lessens or augments her velocity, but gives her a new direction, compounded of the course she steers and the setting of the current.

The method of keeping a journal at sea, and how to correct it: by making proper allowance for the leeway, variation, &c. 1. Leeway is the angle that the rhumb-line, upon which the ship endeavours to sail, makes with the rhumb she really sails upon. This is occasioned by the force of the wind or surge of the sea, when she lies to the windward, or is close hauled, which causes her to fall off and glide sideways from the point of the compass she capes at. Thus let N E S W (fig. 22.) represent the compass; and suppose a ship at C capes at, or endeavours to sail upon, the north point of the compass, and the surge of the sea, she is obliged to fall off, and make her way upon the rhumb CB; then the angle angle CB is the leeway; and if that angle is equal to one point, the ship is said to make one point leeway; and if equal to two points, the ship is said to make two points leeway, &c.

2. The quantity of this angle is very uncertain, because some ships, with the same quantity of sail, and with the same gale, will make more leeway than others; it depending much upon the mould and trim of the ship, and the quantity of water that she draws. The common allowances that are generally made for the leeway, are as follow:

(1.) If a ship is close hauled, has all her sails set, and a moderate gale of wind, she is then supposed to make little or no leeway. (2.) If it blows so fresh as to cause the small sails to be had, it is usual to allow one point. (3.) If it blows so hard that the topsails must be backed, then the common allowance is two points for leeway. (4.) If one top-sail must be handled, then the ship is supposed to make between two and three points leeway. (5.) When both topsails must be handled, then the allowance is about four points for leeway. (6.) If it blows so hard as to occasion the forecourse to be handled, the allowance is between 5 and 6 points. (7.) When both main and fore-courses must be handled, then 6 or 6 points are commonly allowed for leeway. (8.) When the mizen is hauled, and the ship is trying all, she is then commonly allowed about 7 points for leeway.

3. Hence, by knowing the leeway, variation, and course steered, we may from thence find the ship's true course; but if there is a current under foot, then that must be tried, and proper allowances made for it, as has been shown in the section concerning currents, from thence to find the true course.

4. After making all the proper allowances for finding the ship's true course, and making as just an estimate of the distance as we can; yet by reason of the many accidents that attend a ship in a day's running, such as different rates of sailing between the times of hours, the heads of the log, the want of due care at the helm by not keeping her steady but suffering her to yaw and fall off, sudden storms when no account can be kept, &c., the latitude by account frequently differs from the latitude by observation; and when that happens, it is evident there must be some error in the reckoning; to discover which, and where it lies, and also how much of the reckoning, you may observe the following rules:

1st. If the ship sails near the meridian, or within 2 or 2 points thereof, then if the latitude by account disagrees with the latitude by observation, it is most likely that the error lies in the distance run; for it is plain, that in this case it will require a very sensible error in the distance to cause any considerable error in the difference of latitude, which cannot well happen if due care is taken at the helm, and proper allowances are made for the leeway, variation, and currents. Consequently, if the course is pretty near the truth, and the error in the distance runs regularly through the whole, we may, from the latitude obtained by observation, correct the distance and departure by account, by the following analogies, viz.

As the difference of latitude by account is to the true difference of latitude, so is the departure by account to the true departure, and so is the difference by account to the true direct distance.

The reason of this is plain: for let AB, fig. 24, denote the meridian of the ship at A; and suppose the ship sails upon the rhumb AE near the meridian, till by account she is found to be at B; and suppose the true difference of latitude by account is AB; but by observation she is found in the parallel EJ, and so her true difference of latitude is AD, her true direct distance AE, and her true departure DE; then, since the triangles ABC, ADE, are similar, it will be AB : AD :: BC : DE, and AB : AD :: AC : AE.

Example. Suppose a ship from the latitude of 45° 30' north, after having sailed upon several courses near the meridian for 24 hours, her difference of latitude is computed to be upon the whole 95 miles southerly, and her departure 34 miles easterly; but by observation she is found to be in the latitude of 43° 10', and consequently her true difference of latitude is 130 miles southerly; then for the true departure, it will be, As the difference of latitude by account, to the true difference of latitude, is 95 to 130, so is the departure by account to the true departure 46.32, and so is the distance by account 100.9, to the true distance 138.

2dly. If the courses are for the most part near the parallel of east and west, and the ship is sailing in the meridian, or near points of the meridian; then if the latitude by account differs from the observed latitude, it is most probable that the error lies in the course or distance, or perhaps both; for in this case it is evident, that by account will be very nearly true; and thence by the help of this, and the true difference of latitude, may the true course and direct distance be readily found by case 4, of plane sailing.

The form of the log-book and journal, together with an example of a day's work, are here subjoined.

To express the days of the week, we commonly use the characters by which the sun and planets are expressed, viz. O denotes Sunday, X Monday, Z Tuesday, W Wednesday, Y Thursday, & Friday, & Saturday.
NAU

The Form of the Log-Book, with the Manner of working Days Work at Sea.

The Log-Book.

14 x 15. Course. Winds. Observations and Accidents. — Day of —

Fair weather: at four this afternoon I took my departure from the 15°. In the latitude of 5° 00' north, it being N.N.E., distance 5 leagues.

16 1 S W E S. The gale increasing and being under all our sails.

After this morning, frequent showers with thick weather till near noon.

The variation reckoned to be one point westerly.

The Log-Book.

N. S. E. W.

S W 50 46.2 29.4
S 6 W 19 15.6 2.3
S W 49 29.7 48.5
S W 65 24.5 59.2 20.0 20.0
S W 25.2 19.5 19.5

Hence the ship, by account, has come to the latitude of 34° 40' north, and has differed her longitude 5° 05' westerly; so this day I have made my way good S. 31° 31' W. distance 157.4 miles.

At noon the Lizard bore from me N. 31° 31' E. distance 157.4 miles; and having observed the latitude, I found it agreed with the latitude by account.

We have under the article Longitude shown the method of finding the longitude at sea by means of timekeepers. For the method of doing the same by lunar observations, we refer to the Nautical Almanac, and the tables that accompany it.

NAUTIUS, in zoology, a genus belonging to the order of vermices testaceae. The shell consists of one spiral valve, divided into several apartments by partitions. There are 17 species, chiefly distinguished by particularities in their shells.

The most remarkable division of the nautilus is into the thin and thick-shelled kinds. The first is called nautilus pappaceus; and its shell is indeed no thinner than a piece of paper when open to the water. This species is not at all fastened to its shell; but there is an opinion, as old as the days of Pliny, that they are inclosed on the small; and goes on shore to feed. When this species is to sail, it expands two of its arms on high, and between these supports a membrane which it throws out on this occasion; this serves for sail; and the two other arms it hangs out of its shell, to serve occasionally as oars or as a steerage; but this last office is generally served by the tail. When the sea is calm, it is common to see numbers of these worms diverging in this manner; but as soon as a storm rises, or any thing gives them disturbance, they draw in their legs, and take in as much water as makes them specifically heavier than that in which they float; and they sink to the bottom. When they rise again, they void this water by a number of holes, of which their legs are full. The other nautilus, whose shell is thick, never quirs that habituation. This shell is divided into 40 or more partitions, which grow smaller and smaller as they approach the extremity or centre of the shell; between every one of these cells and the adjoining ones, there is a communication by means of a hole in the centre of every one of the partitions. Through this hole there runs a pipe of the whole length of the shell. It is supposed by many, that by means of this pipe the fish occasioned pases from one cell to another; but it seems by no means probable, as the fish must undoubtedly be crushed to death by passing through it. It is much more likely that the fish always occupies the largest chamber in its shell; that is, that it lives in the cavity between the mouth and the first partition, and that it never removes out of this; but that all the apparatus of cells and a pipe of communication, which we so much admire, serves only to admit occasionally air or water into the shell, in such proportion as may serve the creature in its intentions of swimming.

Some authors call this shell the concha margaritifera; but this can be only on account of the thin-coloured inside, which is more beautiful than any other mother-of-pearl; for it has not been observed that this species of fish ever produced pearls. It must be observed, that the polypus is by no means confounded with the powerful-nautilus; but all, notwithstanding the great resemblance in the arms and body of the inclosed fish; nor is the conch ammiculus, so frequently found foul, to be confounded with the thick-shelled nautilus, though the concomitances and general structure of the shell are alike in both; for there are great and essential differences between all these genera.

NAZARITES, among the Jews, persons who either of themselves, or by their parents, were dedicated to the observation of Nazarite-ship. They were of two sorts, namely, such as were bound to this observance for only a short time, as a week or month; and those who were bound to it all their lives. All that we find peculiar in the latter way of life is, that they were to abstain from wine and all intoxicating liquors, and never to shave, or cut off the hairs of their heads. The first Nazarite was to avoid all defilement; and if they chanced to contract any pollution before the term was expired, they were obliged to begin afresh. Wo-

NELL

men as well as men might bind themselves to this vow.

NE. ADMITTAS, in law, a writ directed to the bailiff at the suit of one that is possessor of a church, where, on a quarre impedit, &c. depriving, he is doubtful that the bishop will collate his clerk, or admit the other's clerk, during the suit between them.

NEAT, or NET-WEIGHT, the weight of a commodity alone, clear of the cask, bag, case, or even full.

NEBULOUS, cloudy, in astronomy, a term applied to certain of the fixed stars, which shew a dim hazy light, being less than those of the sixth magnitude, and therefore scarce visible to the naked eye.

NECESSITY. The law charges no man with default where the act is compulsory, and not voluntary, and where there are not a consent and election; and therefore if either there is an impossibility for a man to do otherwise, or so great a perturbation of the judgment and reason as in presumption of law man's nature cannot overcome, such necessity carries a privilege in itself.

Necessity is of three sorts: necessity of conservation of life, necessity of obedience, and necessity of the act of God, or of a stranger.

And first, of conservation of life; if a man steals viands to satisfy his present hunger, this is no felony nor larceny.

The second necessity is of obedience; and therefore where Baron and feme commit a felony, the feme cannot be principal nor accessory, because the Baron intends her to have no will in regard of the subject and obedience she owes her husband.

The third necessity is of the act of God, or of a stranger; as if a man is particular tenant for years of a house, and it should be overthrown by thunder, lightning, and tempest, in this case, he is excused of waste. Bec. Elem. 22, 26, 27.

NECK. See Anatomy.

NECKERIA, a genus of the class and order cryptogamia musc, but little known.

NECTARIUM. See Botany. vol. i. p. 254.

NECTRIS, of the hexandrix digitata class and order: the calyx is one-leafed, six-parted; corolla none; styles pendulous; caps. two; superior ovate, one-seeded; many-seeded; there is one species, native of Guiana.

NECYDALEUS, a genus of insects belonging to the order of coleoptera. The fedeis are staccato; the elys are shorter and narrower than the wings; the tail is simple. There are 11 species, chiefly distinguished by the size and figure of the eyle.
the attendance and service of all his liege-men; but he cannot somewhat man out of the realm, or even the public service, except sea-
men and soldiers, the nature of whose em-
ployment necessarily implies an exception. 1 Black. 138.

This writ is now mostly used where a suit is commenced in the county court, and the party is a man, and he intending to defeat the other of his just demand, or to avoid the justice and equity of the court, is about to go be-

fore sea, or however, that the duty will be

dangerous if he goes.

If the writ is granted on behalf of a subject, and the party is taken, he either gives security by bond in such sum as is demanded, or he satisfies the court by answering (where the answer is not already in) or by affidavit, that he intends not to go out of the realm, and gives such reasonable security as the court directs, and then he is discharged. P. R. C. 292.

NEGLIGENCE, is, where a person neg-
lcts or omits to do a thing which he is

duty to do, a thing which might eventu-
ally be contrary to his interests, and,

beyond all possibility of being

aggravated, and which prevents the

good of another to keep till such a time, and he has a certain recompence or reward for the

keeping, he shall stand charged for in-

jury by negligence, &c.

NEEA, a genus of insects of the order he-

moerpters; the female of this genus is, stout in-

fected; wings long, cross-complicate, cori-

ceous on the upper part; fore-feet cheliform, the

rest formed for walking. This genus is

aquatic, inhabiting stagnant waters, and prey-

ing on the smaller water-insects, &c. The

largest species yet known, and which very far

surpasses in size all the European animals of

the genus, is the nepa grandis, which is a na-

tive of Surinam and other parts of South

America, often measuring more than three

inches in length. Its colour is a dull yellow-

brown, with a few darker shades or varie-

gations; the under wings are of a semi-trans-

parent white colour, and the abdomen is

terminated by a short tubular process, &c.

Nepa cinerea, or the common water-scorp-

ion, is a very frequent inhabitant of stagnant

waters in our own country, measuring about

an inch in length, and appearing, when the

wings are closed, entirely of a dull brown co-

lour; but on the singular shape, resembling

the body appears of a bright red colour

above, with a black longitudinal band down the

middle; and the lower wings, which are of a

fine transparent white, are decorated with red

veins; from the tail proceeds a tubular hind

process or style, nearly of the length of the

body, and which appears single on a general

view, the two valves of which it consists

being generally applied close to each other

throughout nearly their whole length. The animal

is of slow motion, and is often found creeping

about the shallow parts of ponds, &c. In

the month of May it deposits its eggs on the

soft surface of the mud at the bottom of the wa-

ter; they are of a singular shape, resembling

some of the crowned seeds, having an oval

body, and an upper part surrounded by seven

radiating processes or curved spines; the

young, when first hatched, are not more than

the eighth part of an inch in length. The

scorpion flies only at night, when it wanders

about the fields in the neighbourhood of its

native waters. The larve and pupa differ in

appearance from the complete insect, in hav-

ing only the rudiments of wings, and being of

a paler or yellowish colour. See Plate Nat.

Hist. fig. 292.

Nepa cinocols of Linneys differs ma-

terially from the preceding species, and has

at first view more the aspect of a notiona-

t scorpion, but the body is formed for swim-

ning briskly, and furnished with an edging

of hairs on the inner side. This insect is

less common than the preceding, but is found

in similar situations.

Nepa linearis is an insect of a highly sin-

gular aspect, bearing a distant resemblance to

some of the smaller insects of the genera

mantis and phasma. It measures about an

inch and a half from the tip of the snout to the

beginning of the abdominal style or process,

which is itself of equal length to the former

part, and the whole animal is extremely

slender in proportion to its length; the legs,

are also long and slender, and the chelae or

fore-legs much longer in proportion than the

heads of the second species or nepa cinerea; the
colour of the animal is dull yellowish-brown;

the back, when the wings are expanded,

appearing of a brownish-red, and the under

parts pale yellow.

It inhabits the larger kind of stagnant waters, for

entering the shallower parts during the middle

of the day, when it may be observed to pre-

y on the smaller water-insect, &c. Its motions are

singular, often striking out with its legs in a

kind of starting manner at intervals, and con-

tinuing this exercise for a considerable time.

The eggs are smaller than those of the nepa

cinerea, of an oval shape, and furnished with

a ring of hairs diverging from the top of each.

See Plate Nat. Hist. fig. 293.

There are 14 species.

NEPENTHES, a genus of the tetradi-

order annu, in the gynadria class of plants,

and in the natural method ranking among those of which the order is doubtfiul. The calyx is

quadripartite; there is no corolla; the cap-

sule is quadrilocular. There is one species,

a plant of Ceylon.

NEPER'S RODS, or BONES, an instru-

ment mentioned by J. Nepen, Baron of Mer-

chiston, in Scotland, whereby the multiplic-

ation and division of large numbers are much

facilitated.

NEPER'S ROD, the construction of. Sup-

pose the common table of multiplication to be

made upon a plate of metal, ivory, or paste-

board, and then conceive the several columns

(standing downwards from the digits on the head) to be cut asunder; and these

are what we call Nepen's rods for multiplica-

tion. But then there must be a good number

of each; for as many times as any figure is in the multiplcand, so many rods of that species

(i.e. with that figure on the top of it) must

we have; though this rods of each species will

be sufficient for any example in common aff-

airs; there must be also as many rods of 0's.

But before we explain the way of using these rods, there is another thing to be known, viz. that the figures on every rod are written

in an order different from that in the table.

Thus, the little square space or division in

which the several products of every column

are written, is divided into two parts by a

dotted line; and if the figure is written

the lower to the lower; and if the product is

a digit, it is set in the lower division; if it has

two places, the first is set in the lower, and

the second in the upper division; but the
spaces on the top are not divided. Also there is a rod of digits, not divided, which is called the index-rod; and of this we need but one single rod. See the figure of all the single rods, and also between one another, in plate Mised. fig. 174.

Nepeta’s rod, multiplication by. First lay down the index-rod; then on the right of it set the rod whose top is the figure in the highest position of the multiplier; next to this again set the rod whose top is next the figure of the multiplicand; and so on in order to the first figure. Then is your multiplicand tabulated for all the nine digits; for in the line of squares against every figure of the index-rod, you have the product of that figure, and therefore you have no more to do than to transfer the products and sum them. But in taking out these products stand at your table, and the order in which the figures stand obliges you to a very easy and small addition; thus, begin to take out the figures in the lower part, or unit’s place, of the square of the first rod on the right; add the figure in the upper part of the same rod in the lower part of the next, and so on, which may be done as fast as you can look on them. To make this practice as clear as possible, take the following example.

Example to multiply 4768 by 385. Having set the rods together for the number 4768, against 5 in the index I find this number, by adding according to the rule : 23940.
Against 8 this number : 14992.
Against 3 this number : 13394.
Total product : 186098.

To make the use of the rods yet more regular and easy, they are kept in a flat square box, whose breadth is that of ten rods, and the length of that one rod, as thick as it is tall, or (as many as you please) the capacity of the box being divided into ten cells, for the different species of rods. When the rods are put up in the box (each species in its own cell distinguished by the first figure of the rod set before it on the face of the box near the top), as much of every rod stands without the box as shows the first figure of that rod; also upon one of the flat sides without and near the edge, upon the upper hand the index-rod is placed; and also there is a small square, so that when the rods are applied are laid upon this side, and supported by the edge, which makes the practice very easy; but in case the multiplicant should have more than 9 places, the upper face of the box may be made broader. Some make the rods with four different faces and figures on each for different purposes.

Nepeter’s rods, division by. First tabulate your divisor and index, and you have it multiplied by all the digits, out of which you may choose such convenient divisors as will be next less to the figures in the divisor, and write the index answering in the quotient, and multiply down the work as done. Thus 2710758 divided by 6123, gives in the quotient 356.

Having tabulated the divisor, 6123, you see that 6123 cannot be had in 2719; therefore take five places, and on the rods find a number that is equal, or next less to 2719, which is 27107, which is 3 times the divisor, whereof set 3 in the quotient, and subtract 18390 from the figures above, and there will remain 3428; to which add 8, the next figure of the dividend, and seek again on the rod for it, or the next less, which you will find to be five times; therefore set 5 in the quotient, and subtract 35615 from 34285, and there will remain 3573; to which add 5, the last figure in the divisor, and finding it to be just 5 times the divisor, set 5 in the quotient.

Nepeta, Catmint, or Nepeta, a genus of the gymnospermia order, in the dilydynamia class of plants; and in the natural method ranking under the 42d order, verticillata. The under lip of the corolla has a small middle segment created; the margin of the throat is reflexed; the Stamina approach one another. There are 20 species; the most remarkable is the common nepeta, or catmint. This is a native of many parts of Britain, growing about hedges and in waste places. The plant has a bitter taste, and strong smell, not unlike pennyroyal. An infusion of this plant is reckoned a good cephalic and emmenagogue; being found very efficacious in chronic cases. Two ounces of the expressed juice may be given for a dose. It is called catmint, because cats are very fond of it, especially when it is dewed; for then they will roll themselves on it, and tear it to pieces, chewing in them their mouths with great pleasure.

Nephalium, a genus of the pentandria order, in the monocotyledonous class of plants. The male calyx is quinquenervitate; there is no corolla: the female calyx is quadrifoliate; there is no corolla. There are two germens and two styles on each; the fruit are dry, plumose, and monocious; there is one flower, a herb of the East Indies.

Nephritic Wood, lignum nephritim, a wood of a very dense and compact texture, and of a fine grain, brought from us by New Spain, in small blocks, in its natural state, and covered with its bark. It is to be chosen of a pale colour, sound and firm, and such as has not lost its acrid taste; but the surest test of it is the infusing it in water; for if a piece of it infused only half an hour in cold water, gives it a changeable colour, which is blue or yellow, as variously held to the light. If the phial it is in is held between the eye and the light, the tincture appears yellow; but if the eye is placed between the light and the phial, it appears blue.

This wood is a very good diuretic, and is said to be of great use with the Indians in all diseases of the kidneys and bladder, and in suppression of urin, without cause. It is also recommended in fevers and obstructions of the viscera. The way of taking it, among the Indians, is only an infusion in cold water.

Nephritis. See Medicine.

Nereis, in zoology, a genus of animals belonging to the order of vermes mollusca. The body is oblong, linear, and fitted for creeping; it is furnished with lateral pellucid tentacles. There are 11 species, of which the most remarkable are the five following:

1. The nocillio, or nocillitene nereis, which inhabits almost every sea, and is one of the causes of the luminosity of the water.

These creatures shine like glow-worms, but with a brighter splendour, so as at night to make the element appear as if on fire all around. Their bodies are so minute as to evade examination by the naked eye.

It is sometimes called the sea lantern, or the sea firebug; and is thus described by Grusine: the head is roundish and flat, and the mouth acuminated. The two horns or feelers are short and subulated. The eyes are prominent, and placed on each side of the head. The body is composed of about twenty-three segments or joints, which are much less near the tail than at the head. These segments on both sides the animal end in a short conical apex, out of which proceed a number of hairs; from under these-handles the feet grow in the form of small fleshy subulated segments destitute of any thing like claws. It is scarcely two lines long, and is quite pubescent, and its color is that of water, green. They are found upon all kinds of marine plants, but they often leave them, and are found upon the surface of the water; they are frequent at all seasons, but especially in summer before stormy weather, when they are more agitated and more luminous. Their numbers, and wonderful agility, added to their pellucid and shining quality, do not a little contribute to their illuminating the sea, or myriad of those animals may be contained in the portion of a small cup of sea water. Innumerable quantities of them lodge in the cavities of the scales of fishes, and to them probably do the fishes owe their noctilucent quality.

2. Nereis lacustris, or bog nereis (fig. 2.) The body of the size of a hog’s short bristle, transparent, articulated, and on either side at every articulation provided with a short setaceous foot; internally it is furnished with a variety of oval-shaped articulations, and a back formed by two lines bent backwards. It inhabits marshes abounding in clay, where it remains under ground, pushing out its other extremity by motion. When taken out it twists itself up, and is frequent in Sweden.

3. Nereis cirrosa, or waving nereis. The body is red, hemispheric, with sixty-five notches, furnished on both sides with two rows of bristles. At each side of the head ten filaments, at the sides of the mouth many, twice as long as the former. It dwells in Norway, on racks at the bottom of the sea. It vomits a red liquid with which it tingles the water. See much Nat. Hist. fig. 294.

4. Nereis curcula, or blue nereis. It inhabits the ocean, where it destroys the serpula and ceresalis. fig. 393.

5. Nereis elicula, or giant nereis, is a kind of those large worms that make their way into decayed piles driven down into the sea, which they bore through and feed upon, whence they are called sew-worms, or nereis. From head to tail they are beset on either side with small tufts terminating in three points, which are like the fine hair-pencils used by painters, and composed of shining bristles of various colours. The upper part of the body in this worm is all covered with small hairs. The rings of which it is formed are closely pressed together, and yield to the touch. The three rows of small tufts we have been describing, serve this nereis instead of feet, which it uses to go forwards as fishes do their fins. Fig. 296.

Neria, a genus of vermes testacea; the generic character is; animal a limax; shell univalve, spiral, gibbous, flatish at bottom; aperture semi-circular or sub-oval, periphery truncate, flatish. There are about 80 species of this genus.

Nerium, a genus of the monogynia order, in the pentadentia class of plants, and in the natural method ranking under the 30th
order, contorta. There are two erect foli- 
cles; the seeds plump; the tube of the cor-
olla terminated by a lacerated crown. There are 
are usually them natives of the winter climates; the most remarkable of 
which are, 1. The oleander, South Sea rose; 
this is a beautiful shrub, cultivated in gardens 
and an account of its flowers, which are of a fine red, 
and in clusters, but of an indifferent smell; the whole plant is poisonous, and 
especially the bark of the roots. The double 
variety is beautiful, but it should be kept in a 
shrub. 2. The antisyntemer, a native of 
Ceylon, is the bark of this tree is an article of 
the materia medica, under the name of cossist. 
3. The tinctorium, a new species, with beau-
tiful blue flowers, discovered by Dr. Rox-
burgh at Madras. A detection of the leaves, 
with an addition of linseed-water, makes an in-
digo of fine quality. This is the plant of the 
了一句 is a poisonous plant, in that 
respect resembling aconyrum.

NEUTERIA, a genus of the class and or-
der tamieria de dignia; the corolla funnel-
shaped, four cleft; superior berry tax-celled; 
seeds solitary. There is one species, an 
annual of New Zealand.

NEWES, See Anatomy.

NEWTEN, 1st sect. the fol-
lowers of Nestorius, bishop and patriarch 
of Constantinople; who, about the year 439, 
taught that there were two persons in Jesus 
Christ, the divine and the human, which are 
united not hypothetically or substantially, 
but in a mystical manner: whereas he con-
cluded, that Mary was the mother of Christ, 
and not the mother of God. For this opin-
ion, Nestorius was condemned and deposed 
by the council of Ephesus; and the decree 
of this council was confirmed by the emperor 
Theodorus, who banished the bishop to a 
monastery.

NEWETS, in a ship, a sort of 
grates made of small ropes, seized together with rope, 
or a description of the diagonal of a parallelogram, in 
the same time that it would describe the 
sides by those forces.

2. Hence is explained the composition of 
any one direct force out of two oblique 
one, viz. by making the two oblique forces 
the sides of a parallelogram, and the diagonal 
the direct one.

3. The quantity of motion, which is 
collected by adding the sum of the motions 
directed towards the same parts, and the dif- 
erence of forces that are directed to contrary 
parts, suffers no change from the action of bod-
ies among themselves; because the motion 
which one body loses is communicated to 
another.

4. The common centre of gravity of two 
or more bodies does not alter its state of mo-
 tion or rest by the converse of the bodies 
among themselves; and therefore the com-
 mon centre of gravity of all bodies is acting 
on each other, (excluding external actions 
and impediments) is either at rest, or moves 
uniformly in a right line.

5. The modes of bodies included in a 
given space are the same among themselves, 
whether that space is at rest, or moves uni-
formly in a straight line.

6. If bodies, any how moved among 

NEWTONIAN PHILOSOPHY, the doc-
trine of the universe, or the properties, laws, 
affects, actions, forces, motions, &c. of 

bodies, both celestial and terrestrial, as de- 

divered by Newton.

The chief parts of the Newtonian phi-
losophy, as delivered by the author, except his 
the Optical and Astronomical Principles; &c., are contained in his 
Principia, or Mathematical Principles of Na-
tural Philosophy. He founds his system on the 
following definitions.

1. Quantity of matter is the measure 
of the space, arising from its density and bulk 
conjunctly. The ratio of a double density, in 
the same space, is double in quantity; in a 
double space, is quadruple in quantity; in a 
triple space, is sextuple in quantity, &c.

2. Quantity of motion is the measure 
of the same, arising from the velocity and 

Newton defines the following corollaries: 

1. A body by two forces conjoint will 
describe the diagonal of a parallelogram, in 
the same time that it would describe the 
sides by those forces.

2. Hence is explained the composition of 
any one direct force out of two oblique 
one, viz. by making the two oblique forces 
the sides of a parallelogram, and the diagonal 
the direct one.

3. The quantity of motion, which is 
collected by taking the sum of the motions 
directed towards the same parts, and the dif-
erence of forces that are directed to contrary 
parts, suffers no change from the action of bod-
ies among themselves; because the motion 
which one body loses is communicated to 

"Newtonian Philosophy depends chiefly on the following lemmas, especially the first, containing the doctrine of prime and ultimate ratios."
NEWTONIAN PHILOSOPHY.

Leg. 1. Quantities, and the ratios of quantities, which in any finite time converge continuously to equal velocities, and at that time approach nearer the one to the other than by any given difference, become ultimately equal.

Leg. 2. Shews, that in a space bounded by two right lines and a curve, if an infinite number of parallelograms are inscribed, all of equal breadth; then the ultimate ratio of the curve space, and the sum of the parallelograms, will be a ratio of equality.

Leg. 3. Shews, that the same thing is true when the breadths of the parallelograms are unequal.

In the succeeding lemmas it is shewn, in like manner, that the ultimate ratios of the sine, chord, and tangent, of angles infinitely diminished, are ratios of equality; and therefore that in all our reasonings about these, we may safely use the one for the other; that the ultimate form of evanescent triangles, made by the arc, chord, or tangent, is that of similitude, and their ultimate ratio is that of equality; and hence, in reasonings about ultimate ratios, these triangles may safely be used one for another, whether they are made with the sine, chord, or tangent. He then demonstrates some properties of the ordinates of curvilinear figures; and shews that the spaces which a body describes by any finite force urging it, whether that force is determined, and imparts motion to it continually varied, are to each other, in the very beginning of the motion, in the duplicate ratio of the forces; and lastly, having added some demonstrations concerning the evanescence of angles of contact, he proceeds to lay down the mathematical part of his system, which depends on the following theorems.

Theor. 1. The areas which revolving bodies describe by radii drawn to an immovable centre of force, lie in the same incommensurable planes, and are proportional to the times in which they are described. To this proposition are annexed several corollaries, respecting the velocities of bodies revolving by centripetal forces; and the several proportions of those forces, &c., such as, if all the rays from the centre of such a revolving body are reciprocally as the perpendicular let fall from the centre of force upon the line touching the orbit in the place of the body, the body that moves in any curve line described in a plane, and by a radius drawn to a point either immovable or moving forward with an uniform rectilinear motion, describes about that point areas proportional to the times, it is urged by a centripetal force directed to that point. With corollaries relating to such motions in resisting mediums, and to the direction of the forces when the areas are not proportional to the times.

Theor. 2. Every body that moves in any curve line described in a plane, and by a radius drawn to a point either immovable or moving forward with an uniform rectilinear motion, describes about that point areas proportional to the times, it is urged by a centripetal force directed to that point. With corollaries relating to such motions in resisting mediums, and to the direction of the forces when the areas are not proportional to the times.

Theor. 3. Every body that, by a radius drawn to the centre of another body, any how moved, describes areas about that centre proportional to the times, is urged by a force compounded of the centripetal forces tending to that other body, and of the whole accelerative force by which that other body is impelled. With several corollaries.

Theor. 4. If the centripetal forces of bodies which by equal radii move in different circles, tend to the centres of the same circles; and are to one the other as the squares of the arcs described in equal times, applied to the radii of the circles. With many corollaries relating to the velocities, times, periods, and forces, &c. And, in a scholiast, the author further acquaints us with the means of deducing the foregoing proposition and its corollaries, we may discover the proportion of a centripetal force to any other known force, such as that of gravity. For if it be, by means of its gravity, resolved in a circle concentric to the earth, this gravity is the centripetal force of that body. But from the descent of heavy bodies, the time of one entire revolution, as well as the arc described in any given time, is found by a certain method.

On these and such-like principles depends the Newtonian mathematical philosophy. The author farther shews how to find the centre to which the forces compelling any body are directed, having the velocity of the body given; and finds that the centripetal force is always as the versed sine of the nascent arc directly, and as the square of the time inversely, or directly as the square of the velocity quadratically. And therefore the nascent arc. From these premises, he deduces the method of finding the centripetal force directed to any given point when the body revolves in a circle; and this, whether the centre is near the place of descent; so that all the lines drawn from it may be taken for parallels. And he shews the same thing with regard to bodies revolving in spirals, ellipses, hyperbolae, or parabolae. He concludes, having the facility of the orbes given, to find the velocities and moving powers; and indeed resolves the most difficult problems relating to the celestial bodies with a surprising degree of mathematical skill. These problems and demonstrations are all contained in the first book of the Principia; but an account of them here would neither be generally understood, nor can be comprised in the limits of this work.

In the second book, Newton treats of the properties and motion of fluids, and their powers of resistance, with the motion of bodies through such resisting mediums, those resistances being in the ratio of any powers of the velocity, the resistance being either made in right lines or curves, or vibrating like pendulums.

On entering upon the third book of the Principia, Newton briefly recapitulates the contents of the two former books in these words: "In the preceding books I have laid down the principles of philosophy, principles not philosophical, but mathematical; such, to wit, as we may build our reasonings upon in philosophical enquiries. These principles are, the laws and conditions of certain motions, and powers or forces, which chiefly have respect to philosophy. But lest they should have appeared of themselves dry and barren, I have illustrated them here and there with some philosophical scholiasts, giving an account of such things as are of more general nature, and which philosophy seems equally to be founded on; such as the density and the resistance of bodies, spaces void of all matter, and the motion of light and sounds. It remains, he adds, that from the same principles I now demonstrate the frame of the system of the world. Upon this subject I shall have composed the third book in a popular method, that it might be read by many. But afterwards considering that such as had not sufficiently entered into the principles could not easily discern the strength of the consequences, nor lay aside the prejudices to which they had been many years accustomed, to shew there from the foregoing propositions and its corollaries, which might be raised upon such accounts, I chose to reduce the substance of that book into the form of propositions, in the mathematical way, which should be read by those only who had first made themselves masters of the principles established in the preceding books."

As a necessary preliminary to this third part, Newton lays down rules for reasoning in natural philosophy.

The phenomena first considered are, 1. That the satellites of Jupiter, by radii drawn to his centre, describe areas proportional to the times of description; and that their periodic times, the fixed stars being at rest, are in the same proportion to their distances from that centre. 2. The same thing is likewise observed of the phenomena of Saturn. 3. The five primary planets, Mercury, Venus, Mars, Jupiter, Saturn, with their several orbits, describe certain areas in the same times, the fixed stars being supposed at rest; the periodic times of the said five primary planets, and of the earth, about the sun, are in the same proportion to their mean distances from the sun. 4. The planetary orbits, by radii drawn to the earth, describe areas in no way proportional to the times; but the areas which they describe by radii drawn to the sun are proportional to the times of description. 6. The moon, by a radius drawn to the earth, describes an area proportional to the time of description. All which phenomena are clearly evinced by astronomical observations. The mathematical demonstrations are next applied by Newton in the following propositions.

Prop. 1. The forces by which the satellites of Jupiter are continually drawn off from rectilinear motions, and retained in their proper orbits, tend to the centre of that planet, and are reciprocally as the squares of the distances of those satellites from that centre.

Prop. 2. The same thing is true of the primary planets, with respect to the sun's centre.

Prop. 3. The same thing is also true of the moon, in respect of the earth's centre.

Prop. 4. The moon, moving towards the earth; and by the force of gravity is continually drawn off from a rectilinear motion, and retained in her orbit.

Prop. 5. The same thing is true of all the other planets, both primary and secondary, each with respect to the centre of its motion.

Prop. 6. All bodies gravitate towards every planet; and the weights of bodies towards any one and the same planet, at equal distances from its centre, are reciprocally as the squares of the distances of matter they contain.

Prop. 7. There is a power of gravity tending to all bodies, proportional to the several quantities of matter which they contain.

Prop. 8. In two spheres mutually gravitating each towards the other, if the matter in places on all sides, round about, and equidistant from the centres, is similar, the weight of either sphere towards the other, will be reciprocally as the square of the distance between their centres. And if we should sum together the weights of bodies towards different planets; hence also are discovered the quantities of matter in the several planets; and hence
When heated in an open vessel, it combines with oxygen, and assumes a green colour; and if the heat is continued, acquires a hue of sulphur and phosphoric acid. Crook cott found that sulphuret of nickel may be easily formed by fusion. The sulphuret which he obtained was yellow and hard, with small sparkling facets; but the nickel which he employed was impure.

Phosphuret of nickel may be formed either by fusing nickel along with phosphoric glass, or by dropping phosphorus into it while red hot. It is of a white colour, and when burned, it exhibits the appearance of very slender prisms collected together. When heated, the phosphorus burns, and the metal is oxidized. It is composed of 83 parts of nickel and 17 of phosphorus. The nickel however on which this experiment was made, was not pure.

Nickel is not acted upon by azote, nor does it combine with muriatic acid.

The alloys of this metal are but very imperfectly known. With gold it forms a white, hard, brittle alloy, easily oxidized when exposed to the air; with iron it combines very readily, and forms an alloy whose properties have not been sufficiently examined; with tin it forms a white, hard, brittle mass, which swells up when heated; with lead it does not combine without difficulty; with silver and mercury it refuses to unite; with combination with platinum has not been tried.

The affinities of nickel, and its oxides, are, according to Bergman, as follows:

**Nickel**

- Iron
- Cobalt
- Arsenic
- Copper
- Gold
- Tin
- Antimony
- Platinum
- Bismuth
- Lead
- Silver
- Zinc
- Sulphur
- Phosphorus
- Boracic
- Prussic
- Carbonic

**Oxide of Nickel**

- Oxalic acid
- Muratic acid
- Sulphuric acid
- Tartaric acid
- Nitric acid
- Phosphoric acid
- Fluoric acid
- Soatic acid
- Benzoic acid
- Citric acid
- Lactic acid
- Acetic acid
- Arsenie
- Phosphoric acid
- Boracic
- Prussic
- Carbonic

Nickel, like gold, is to a great extent valueless to the poor. The cost of mining nickel is not great, but the cost of the metal is very high. It is not known to exist in any quantity in the United States, but it is found in small quantities in the western provinces of Canada. It was first discovered in America by the Spaniards about the year 1566, and by them imported into Europe. It had been used by the inhabitants of America long before; and was called by those of the islands yoll, and pruta by the inhabitants of the continent. It was sent into Spain from Tabaco, a province of Yucatan, where it was first discovered, and whence it takes its common name.

There are two varieties of that species of nicotiana which is cultivated for common use; and which are distinguished by the names of Oranokeo, and sweet-scented Tabacco. They differ from each other in the figure of their leaves; those of the former being longer and narrower than the latter. They are tall herbaceous plants, growing to an height of 2 feet, and rising with a strong stem from a white, or yellow, tuber. The stalk, near the root, is upward of an inch diameter, and surrounded with a kind of hairy or yellowish substance, of a yellowish tinge. The leaves are rather of a deeper green, and four or five inches long, and almost at the distance of two or three inches from each other. They are oblong, of a spear-shaped oval, and simple; the largest about eighteen inches long, and exceedingly small in the upper leaves, and than five inches long. The leaves are of a greenish yellow, and acquire a yellowish cast. The stem and branches are terminated by large bunches of flowers, collected in clusters of a delicate red; the edges, when full-blown, inclining to a pale yellow. They continue in succession till the end of the summer; their leaves are of brown colour, and sometimes spotted with a small black spot, containing about 1000; and the whole produce of a single plant is reckoned at about 350,000. The seeds ripen in the month of September.

Mr. Caver informed us, that the Oranokeo, or, as it is called, the long Virginia tobacco, is the kind best suited for bearing the rigour of a northern climate; the strength, as well as the scent, of the leaves, being greater than that of the other; and that the sweet-scented sort, which is said to have a more pungent and strong odour, is not so much esteemed by the tobacco-growing public. The climate of Virginia, too, is generally considered as more favourable to the growth of tobacco than that of any other country in the world. Tobacco thrives best in a warm, kindly, rich soil, that is not subject to be overrun by weeds. In Virginia the soil in which it thrives best is warm, light, and in which the tobacco is well managed, is the seed: nor is it possible that the plant is to be cultivated in Britain, it ought to be planted in a soil as nearly of the same kind as possible. Other kinds of soil might probably be brought into cultivation, but we must rest under the conviction, that whatever mixture of manure we may use, that whatever mixture of manure we may use, and that whatever mixture of manure we may use, and that whatever mixture of manure we may use.
be thoroughly incorporated with the soil. The best site for a tobacco-plantation is the southern declivity of a hill rather gradual than abrupt, or a spot that is sheltered from the north winds; but at the same time it is necessary that the plants enjoy a free air; for without that they will not grow. 

Having sown the seed, on the least appearance of frost after the plants appear, it will be necessary to spread mats over the beds, a little elevated from the ground by poles laid across, that they may not be crushed. When the tobacco has risen to the height of four, it commonly begins to put forth the branches on which the flowers and seeds are produced; but as this expansion, if suffered to take place, would drain the nutrition from the leaves, which are the most valuable part, and thereby lessen their size and efficacy, it becomes needful at this stage to nip off the extremity of the stalk to prevent its growing higher, in some climates the top is commonly cut off when the plants are but two or three inches high. Tobacco is intended to be a little stronger than usual, this is done when it has only 13.

The apparent signs of maturity are these: the leaves, as they approach a state of ripeness, become more corrugated or rough; and when fully developed, with yellow spots on the raised parts; whilst the cavities retain their usual green colour.

Tobacco is subject to be destroyed by a worm; and without proper care to exterminate this enemy, a whole field of plants may soon be lost. This animal is of the homed species, and appears to be peculiar to the tobacco-plant; so that in many parts of America it is distinguished by the name of the tobacco-worm. In what manner it is first produced, or how propagated, is unknown; but it is not discernible till the plants have attained about half their height; and then appears to be nearly as large as a grain. Soon after this it lengthens into a worm; and by degrees increases in magnitude to the size of a man's thumb. It is regular in its form, with its head to its tail, without any diminution at either extremity. The colour of its skin is, in general, green, interspersed with several spots of a yellowish white; and the whole covered with a glittering dust, which is removed by brushing. These worms are found the most predominant during the end of July and the beginning of August; at which time the plants must be particularly attended to, and every leaf carefully searched. As soon as a wound is discovered (and it will not be long before it is perceptible), care must be taken to destroy the cause of it, which will be found near it, and from its unctuous texture may easily be removed. 

When the tobacco is fit for being gathered, on the first morning that promises a fair day, before the sun is risen, take an axe or a long knife, and holding the stalk near the top with one hand, sever it from its root with the other, as low as possible. Lay it gently on the ground, taking care not to break off the leaves, and there let it remain exposed to the rays of the sun throughout the day, or until the leaves, according to the American custom, are thoroughly cured; that is, till they become limber, and will bend away without breaking. But if the weather should prove rainy without any intervals of sunshine, and the plants appear to be fully ripe, they must be housed immediately. This must be done, however, with great care that the leaves, which are in this state very brittle, may not be broken. They are next to be placed under proper shelter, either in a barn or covered lay, so that they cannot be affected by rain or too much air, thinly scattered on the floor; and if the sun does not appear for several days, they must be left to wilt in that manner; but in this case the quality of the tobacco will not be quite so good.

When the leaves have acquired the above-mentioned flexibility, the plants must be laid in heaps, or rather in one heap if the quantity is not too great, and in about 24 hours they will be found to sweat. But during this time, when they have lain for a little while, and begin to ferment, it will be necessary to turn them; bringing those which are in the middle to the surface, and placing those which are at the surface in the middle. The longer they lie in this situation, the darker-coloured the tobacco. After they have lain for three or four days, for a longer continuance might make the plants turn mouldy, they may be fastened together in pairs with cords or wooden pegs, near the bottom of the stalk, and hung across a pole, with the leaves suspended in the same covered place, a proper interval being left between each pair. In about a month the leaves will be thoroughly dried, and of a proper temperature to be taken down. This state may be ascertained by their appearing of the same colour with those imported from America. But this can be done only of tobacco, which is excessively apt to attract the humidity of the atmosphere, which gives it a pliability that is absolutely necessary for its preservation; for if the plants are removed in a very dry season, the external parts of the leaves will crumble into dust, and a considerable waste will ensue.

Care.—As soon as the plants are taken down, they must again be laid in a heap, and covered with wet straw; but capers are always put in about the 3rd week; but this climate may possibly require a longer time. While they remain in this state it will be necessary to introduce your hand frequently into the heap, to discover whether the leaves can be pressed; for in larger quantities this will sometimes be the case, and considerable damage will be occasioned by it. When they are found to heat too much, that is, when the heat exceeds a moderate degree of warmth, the top of the weight by which they are pressed must be taken away; and the cause being removed, the effect will cease. This is called the second, or last sweating, and, when completed, which it generally will be about the time just mentioned, the leaves may be stripped from the stalks for use. Many, however, omit this last sweating.

When the leaves are stripped from the stalks, they are to be tied up in bunches or laps, and kept in a cellar or other damp place; though if not handled in dry weather, but only during a rainy season, it is of little consequence in what part of the house or barn they are laid up. At this period the tobacco is thoroughly cured, and is proper for manufacturing as that imported from the colonies. Tobacco is made up into rolls by the in-
crystallizes

NIMBUS, in antiquity, a circle observed on certain medals, or round the head of some emperors, answering to the circles of light drawn around the images of saints. The name is given to the constellations of Mauritius, Ptolemy, and others, even of the upper empire. See also Meteorology.

NIPA, a genus of the natural order of palms. The male has a spath; the corolla is six-petalled. The female has a spath; corolla none; lip circular.

There is one species, native of the E. Indies. The leaves are used in making mats.

NIPPERS, in a ship, are small ropes about a fathom or two long, with a little truck at one end, and sometimes only a wale-knot. Their use is to help holding off the cable from the main or jigger-capstan, where the cable is so shaggy, so wet, and so great, that they cannot strain it, to hold it off with their bare hands.

NISI PRIUS, in law, a commission directed to the judges of assize, empowering them to try all questions of fact issuing out of the courts at Westminster, which are then ready for trial by jury. The original of which name is this: all causes connected in the courts of Westminster-hall are, by course of the courts, appointed to be tried on a day fixed in some Easter or Michaelmas term, by a jury returned from the county wherein the causes are assizes; but with this proviso, nisi prius justice was and assigned vestiary: that is, unless before the day prefixed the judges of assize come into the county in question, which they always do in the vacation preceding each Easter and Michaelmas term, and there try the cause. And then, upon the return of the verdict given by the jury to the court above, the judges there give judgment for the party to whom the verdict is a Black. 29. See Assizes.

NISOLS, in crystallography, the decamaria star, in the diapedia class of plants, and in the natural method ranking under the 52d order, papilionaceae. The calyx is quinque- dentate; the capsule monospermous, and terminated by a single wing. There are two species, tree of Carthageni.

NITIDULA, a genus of insects of the coleoptera order. The generic character is, antennae clavate, the club solid; shells margined; head prominent; thorax a little flattened, margined. There are upwards of 30 species of this genus.

NITRARIA, a genus of the monogynium order, in the dodecanmia class of plants, and in the natural method ranking with those of which the order is doubtful. The corolla is pentapetalous, with the petals arched at the top; the calyx eximant; the stamens 12; the fruit a monospermous plum. There is one species, a shrub of Siberia.

NITRATS, salts formed by the nitric acid. The most important of the nitrates have been long known; and in consequence of the quantities which they possess, no class of bodies has excited greater attention, or been examined with more unwearied industry. See Nitre. They may be distinguished by the following properties:

1. Soluble in water, and capable of crystallizing by cooling of 2. When heated to redness, along with combustible bodies, a violent combustion and detonation are produced. 3. Sulphuric acid denatures from them fumes, which have the odour of nitric acid. 4. When heated, this acid and the oxymuriatic acid is exhaled. 5. Decomposed by heat, and yield at first oxygen gas. The nitrates at present known are 12 in number. Few of them combine with an excess of acid, and the nitrates are almost any supernitrates, or subnitrates.

NITRE, or nitrat of potash. As this salt, known also by the name of saltpetre, is produced naturally in considerable quantities, particularly in Egypt, it is highly probable that the patients were acquainted with it; but scarcely anything certain can be collected from their writings. If Pliny mentions it at all, he confounds it with soda, which was known by the names of nitrum and nitrata. It is certain, however, that it has been known from time immemorial. Roger Bacon mentions this salt in the 13th century under the name of nitrite.

No phenomenon has excited the attention of chemists philosophers more than the continuous reproduction of nitre in certain places, and that it is not produced from them. Inordinate quantities of this salt are necessary for the purposes of war; and as nature has not laid up great magazines of it, as she has of other salts, this annual reproduction is the only source from which it can be procured. It became therefore of the utmost consequence, if possible, to discover the means which nature employed in forming it, and in order to enable us to imitate her processes by art, or at least to accelerate and facilitate them at pleasure. Numerous attempts accordingly have been made to explain and to imitate these processes.

Lemery the younger advanced, that all the nitre obtained exists previously in animals and vegetables; and that it is formed in these substances by the processes of vegetation and mineralization. But it was soon discovered that nitre exists, and is actually formed, in many places where no animal nor vegetable substance is decomposed; and decomposed, and consequently this theory was as untenable as the former. So far indeed is it from being true that nitre is formed by these processes alone, that the quantity of nitre in plants has been found to depend entirely on the soil in which they grow.

At last, by the numerous experiments of several French philosophers, particularly those of Thouvenel, it was discovered that nothing else is necessary for the production of nitre than a basis of lime, heat, and an open but not too free communication with dry atmospheric air. When these circumstances combine the acid is first formed, and afterwards the alkali makes its appearance. How the furnaces furnishes materials for this production is easily explained, now that the component parts of the nitric acid are known to be oxygen and azote; but how lime contributes to their union it is not so easy to see. The occurrence of the potass is equally extraordinary. If any thing can give countenance to the hypothesis that potass is composed of lime and azote, it is this singular fact.

Nitre is found abundantly on the surface of the earth in India, South America, and even in some parts of Spain. In Germany and France it is obtained by means of artificial nitre-beds. They consist of the refuse of animal and vegetable bodies undergoing slow decomposition, and various decarburates and other earths. It has been ascertained that if oxygen gas is presented to azote at the instant of its disengagement, nitric acid is formed. This seems to explain the origin of the acid in the nitrates. The azote decomposed from these putrefying animal substances combines with the oxygen of the air. The potass is probably furnished, partly at least, by the vegetables and the soil.

The nitre is extracted from these beds by liquifying the earthy matters with water. This water, when sufficiently impregnated, is evaporated, and a brown-coloured salt obtained, known by the name of crude nitre. It consists of nitre, common salt, nitrate of lime, and various others. The foreign salts are either separated by repeated crystallizations, or by washing the salt repeatedly with small quantities of water; for the foreign salt being more soluble are taken up first.

Nitre, when quick, is obtained in six-sided prisms, terminated by six-sided pyramids; but for most purposes it is preferred in an irregular mass, because in that state it contains less water. The primitive form of its crystals, according to Hauy, is a rectangular hexahedron, composed of two four-sided pyramids applied base to base; two of the sides are inclined to the other pyramid at an angle of 120°; the other four are in the plane of the six-sided prism. The form of its integrant particles is the tetrahedron. The six-sided prism is the most common form which it assumes. Sometimes, instead of six-sided pyramids, these prisms are terminated by 18 facets, disposed in three ranges of six, as if three truncated pyramids were piled on each other; sometimes it crystallizes in tabular.

The specific gravity of nitre is 1.9309. Its taste is sharp, bitter, and cooling. It is very brittle. It is soluble in seven times its weight of water at the temperature of 60°, and in nearly its own weight of boiling water. It is not altered by exposure to the air.

When exposed to a boiling heat, part of the salt is evaporated away, and the remainder crystallized in an opaque mass, which has been called mineral crystal. When ever it melts it begins to disengage oxygen, and by keeping it in a red heat about the third of its weight of that gas may be obtained; towards the end of the process azotic gas is disengaged. If the heat is continued long enough the salt is completely decomposed, and pure potass remains behind.

It detonates more violently with combustible bodies than any of the other nitrates. When mixed with one-third part of its weight of charcoal, and thrown into a red-hot crucible, or when charcoal is thrown into red-hot nitre, detonation takes place, and one of the most brilliant products of that can be exhibited. The residuum is carbaceous potass. It was formerly called nitre fixed by charcoal. A still more violent detonation is produced by using phosphorus instead of charcoal. When
NITRIC

A mixture of nitré and phosphorus is struck smartly with a hot hammer a very violent detonation is produced. Nitre oxidizes all the metals at a red heat, even gold and platinum.

Nitre, according to Bergman, is composed of:

<table>
<thead>
<tr>
<th>Acid</th>
<th>Potass</th>
<th>Water</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>61</td>
<td>8</td>
</tr>
</tbody>
</table>

According to the latest experiments of Kirwan, after being dried in the temperature of 70°, it is composed of:

<table>
<thead>
<tr>
<th>Acid</th>
<th>Potass</th>
<th>Water</th>
</tr>
</thead>
<tbody>
<tr>
<td>44.0</td>
<td>51.8</td>
<td>4.2</td>
</tr>
</tbody>
</table>

Nitre is decomposed by the following salts:
1. Sulphates of soda, ammonia, magnesia, alumina.
2. Murat and acetate of barytes.

One of the most important compounds formed by means of nitre is gunpowder, which consists of nitre and clay. It was afterwards deominated aquafortis, and spirit of nitre. The name nitre was first given it in 1767 by the French chemists; it was immediately before called nitric acid.

1. It is generally obtained in large manufactories by distilling a mixture of nitre and clay; but the acid procured by this process is weak and impure. Chemists generally prepare it by distilling three parts of nitre and one of sulphuric acid in a glass retort. The neck of the retort must be heated into a receiver, from which there passes a glass tube into a bottle with two months, containing a little water, and furnished with a tube of safety; which is a tube open at its upper end, and having its lower end plunged in water. The water prevents any communication between the external air and the inside of the apparatus.

The air, which has accumulated in the vessels, is to be formed within the vessels, the external air reaches down through the tube, and prevents any injury to the vessels. On the other hand, if air is generated in the vessels it forces the water up the tube, the height of which becomes thus the measure of the elasticity of the air in the vessels. By this convection the apparatus is in no danger of being broken, which otherwise might happen.

From the other mouth of this bottle there passes a tube into a pneumatic apparatus to collect the gas which is evolved during the process. The retort is to be heated gradually almost to redness. The nitric acid comes over, and is condensed in the receiver; while the common air of the vessels, and a quantity of oxygen gas which is evolved, especially towards the end of the process, passes into the pneumatic apparatus, and the water in the bottles is evaporated with some acid which is not condensed in the receiver.

The acid thus obtained is of a yellow colour, and almost always contains mutric and sometimes sulphuric acid. These may be removed by distilling it over again with a moderate heat, and changing the receiver after the first portion, which contains all the foreign acids, has passed. It still contains a quantity of nitric acid, to which it owes its colour and the red fumes which it exhales. This gas may also be expelled by the application of heat. Pure nitric acid remains behind, transparent and colourless, like water.

When newly prepared in this manner it is a liquid as transparent and colourless as water; but the affinity between its component parts is so weak, that the action of light is sufficient to drive off a part of its oxygen in the form of gas; and thus, by converting it partly into nitrous gas, to make it assume a yellow colour. Its taste is exceedingly acid and peculiar. It is very corrosive, and tinges the skin of a yellow colour, which does not disappear till the epidermis comes off. It is constantly emitting white fumes which have an acid disagreeable odour.

It has a strong affinity for water, and has never yet been obtained except mixed with that liquid. When concentrated it attracts moisture from the atmosphere, but not so powerfully as sulphuric acid. It also produces heat when mixed with water, owing evidently to the concentration of the water.

The specific gravity of the strongest nitric acid that can be procured is 1.583; but at the temperature of 60°, Mr. Kirwan could not procure it stronger.

As this liquid acid is a compound of two ingredients, namely, pure nitric acid and water, it becomes an object of the greatest consequence to ascertain the proportion of each of these parts. This problem has lately occupied the attention of Mr. Kirwan, who has endeavoured to solve it in the following manner:

He dried a quantity of crystallized carbonate of soda in a red heat, and dissolved it in water, in such a proportion that 367 grains of the solution contained 50.03 grains of alkali. He saturated 370 grains of this solution with 147 grains of nitric acid, the specific gravity of this solution being 1.234, and which contained 45.7 per cent. of acid, of the specific gravity 1.534, chosen by him as a standard. The carbonic acid driven off amounted to 14 grains. Adding 890 grains of water to the other 807, the quantity contained in the solution, at the temperature of 60°, was 1.0401. By comparing this with a solution of nitrate of soda, of the same density, he found that the salt contained in it amounted to 16.501 of the whole. There was an excess of acid of about two grains. The weight of the whole was 1439 grains; the quantity of salt consequently was 56.91 = 85.142 grains. The quantity of alkali was 50.05 + 14 = 56.05. The quantity of standard acid employed was 60.7. The whole therefore amounted to 102.75 grains; but as only 85.142 grains entered into the composition of the salt, the remaining 17.608 must have been pure water mixed with the nitric acid. But if 60.7 of standard acid contain 17.608 of water, 100 parts of the same acid must contain 26.38. One hundred grains of pure nitric acid, therefore, are composed of 73.62 parts of pure nitric acid and 26.38 of water.

Mr. Davy considers as pure acid the per-
with a portion of its oxygen nitrous gas and muriatic gas being evolved.

It is capable of oxidizing all the metals, except gold, platinum, and titanium. It appears, from the experiments of Scheffer, Bergman, Sage, and Tillet, that nitric acid is capable of dissolving (and consequently of oxidizing) a very minute quantity even of gold.

It even sets fire to zinc, bismuth, and tin, if it is poured on them in fusion, and to filings of iron if they are perfectly dry.

Nitric acid combines with alkalies, earths, and the oxides of metals, and forms compounds, which are called nitrates.

The order of its affinities is as follows:

Barytes, Potass, Soda, Strontian, Lime, Magnesia, Ammonia, Glucina, Alumina, Zirconia.

Nitric acid is one of the most important instruments of analysis which the chemist possesses; nor is it of inferior consequence when considered in a political or commercial view, as it forms one of the most essential ingredients of gunpowder. Its nature and composition accordingly have long occupied the attention of philosophers; and from their experiments it appears, that nitric acid is composed of azote and oxygen; consequently nitric gas is also composed of the same ingredients. And as nitric gas absorbs oxygen, even from common air, and forms with it nitric acid, it is evident that nitric acid contains more oxygen than nitric gas. But it is exceedingly difficult to ascertain the exact proportions of the component parts of this acid. Lavoisier concluded, from his experiments on the decomposition of nitre by charcoal, that nitric acid is composed of one part of azote and four parts of oxygen. But Davy has shewn that this decomposition is more complicated than had been supposed; and that Lavoisier's experiments by no means warrant the conclusion which he drew from them. Cavendish, on the other hand, concluded, from his experiments, that the acid which he formed, by combining together azote and oxygen by means of electricity, is composed of one part of azote and 2.346 of oxygen. With this result the late experiments of Mr. Davy corresponded very nearly. He formed his standard acid by combining together known quantities of nitrous gas and oxygen. According to him, 100 parts of pure nitric acid are composed of

29.5 azote
70.5 oxygen
100;

or 1 part of azote, and 3.39 of oxygen.

Nitric acid is seldom in a state of absolute purity, holding usually a certain portion of nitrous gas in solution. In this state it is distinguished by the name of nitrous acid; a compound of considerable importance. See Nitrous Acid.

NITRITES, are salts formed from nitrats, saturated with nitrous gas. See Nitrats.

The existence of nitrous acid was pointed out by Bergman and Scheele; the two philosophers to whom we are indebted for the first precise notions concerning the difference between nitric and nitrous acids. They could not be formed by combining directly nitric acid with the different earthy and alkaline bases; nor have any experiments made to combine nitrous gas with the nitrats been attended with success.

The only method of obtaining these salts at present known, is that which was long ago pointed out by Bergman and Scheele. It consists in exposing a nitrat to a pretty strong heat till a quantity of oxygen gas is disengaged from it. What remains in the retort after this process is a nitrite; but the length of time necessary for producing this change has not yet been ascertained with any degree of precision. If the heat is applied too long the nitrat will be totally decomposed, and nothing but the base will remain, as happened to some of the French chemists on attempting to repeat the process of Bergman and Scheele.

Nitrite of potass is the only salt formed by this process, of which an account has been given. Scheele's process for obtaining it is as follows: Fill a small retort with nitrate, and keep it red-hot for half an hour. When it is allowed to cool, it is found in the state of a nitrite. It deliquesces when exposed to the air; and red vapours of nitrous acid are exhaled when any other acid is poured upon it.

As the nitrates have never been examined by chemists, and as it has not even been determined whether any considerable number of the nitrats can be converted into these salts, it would be in vain, in the present state of our knowledge, to attempt a particular description of them. It may, however, be considered as exceedingly probable that no such salts as the nitrates of ammonium, gluclina, ytria, alumina, and zirconia, exist or can be formed, at least by the process of Scheele; for those bases are decomposed completely by the action of a heat too moderate to hope for the previous emission of oxygen gas.

From the few observations that have been made upon them, it appears that the nitrates are in general deliquescent, very soluble in water, decomposable by heat as well as nitrates; that their taste is cooling like that of the nitrats, but more acid and nitrous; that by exposure to the air they are gradually converted into nitrates by absorbing oxygen; but this change takes place exceedingly slowly.

NITRO-MURIATIC ACID. When muriatic acid is mixed with nitric acid, the mixture is nitro-muriatic acid, which was formerly known by the name of aqua-regia.

NITRIC ACID. The liquid at present called nitric acid by chemists, may be formed by causing nitrous gas to pass through nitric acid. The gas is absorbed, and the acid assumes a yellow colour; and its specific gravity is diminished. It is then denominated nitric acid. It is always in this state that it is seen perfectly clear in a mixture of sulphuric acid and nitre. The acid of commerce is always nitric acid. The nitric and nitrous acids were first distinguished with accuracy by Scheele.

The nature of nitric acid was first investigated by Dr. Priestley, who demonstrated, by very curious experiments, that it is a compound of nitric acid and nitrous gas. This opinion was embraced, or rather it was first fully developed, by Morveau. But the theory of Lavoisier, which supposed the difference between nitric and nitrous acids to depend merely on the first containing a greater proportion of oxygen than the second, for some time drew the attention of chemists from the real nature of nitric acid. Raymond published his dissertation in 1796, to demonstrate the truth of the theory of Priestley and Morveau; and the same thing has been done still more lately by Messrs. Thomson and Davy. At present it is allowed by every one, that nitric acid is merely nitric acid more or less impregnated with nitrous gas.

This being the case, and nitric acid being capable of absorbing very different proportions of nitrous gas, it is evident that there must be a great variety of nitrites, differing from each other in the proportion of nitrous gas which they contain; unless we choose to confine the term nitric acid to the compound formed by saturating nitric acid completely with nitrous gas.

When nitrous gas is placed in contact with nitric acid, the acid absorbs it slowly, and acquires first a pale-yellow colour, then a bright yellow. When a considerable portion of nitrous gas is absorbed, the acid becomes dark-orange, then olive, which increases in intensity with the gas absorbed; then it becomes of a bright green; and, lastly, when fully saturated, it becomes bluegreen. Its volume and its volatility also increase with the quantity of gas absorbed; and when fully saturated it assumes the form of a dense vapour, of an exceedingly suffocating colour, and difficulty combustible by water. In this state of saturation it is distinguished by Dr. Priestley by the name of nitrous acid vapour. It is of a dark-red colour, and passes through water partly without being absorbed. The quantity of nitrous gas absorbed by nitric acid is very great. Dr. Priestley found, that a quantity of acid, equal in bulk to four pennyweights of weight, absorbed 130 ounce-measures of gas without being saturated. The component parts of nitrous acid, its gravity and densities, may be seen in the following table, drawn up by Mr. Davy, from experiments made by him on purpose, with much precision:

The colour of nitrous acid depends, in some measure, also on the proportion of water by which it is converted into yellow nitrous acid concentrated, a fourth part by weight of water is added, the colour is changed to a fine green; and when equal parts of water are added, it becomes blue. Dr.
Priestley observed, that water impregnated with this acid in the state of vapour becomes first blue, then green, and lastly yellow. A green nitrous acid became orange-coloured while hot, and retained a yellow tinge when cold. A blue acid became yellow on being heated in a closed glass vessel, but on cooling, became green, and afterwards a deep blue; and when exposed to air resumed its original colour. When nitric acid is exposed to heat the nitrous gas is expelled, and nitric acid remains behind. If this gas, however, is carried along with it a quantity of acid, especially if the acid is concentrated. But nitric acid vapour is not altered in the least by exposure to heat.

It is not altered by oxygen gas, common air, nor by azotic gas.

The simple combustibles and metals act upon it precisely as on nitric acid. It answers much better than nitric acid for inflaming oils and for similar bodies.

It converts sulphuric and phosphoric acids into sulphuric and phosphoric.

Nitrous acid vapour is absorbed by sulphuric acid, but seemingly without producing any change; if any change is produced, the mixture, the heat produced expels it in the usual form of red fumes. The only singular circumstance attending this impregnation is, that it disposits the sulphuric acid to crystallize.

 Nobility, a quality that enables, and raises a person possessed of it above the rank of a commoner.

The civil state of England consists of the nobility and gentry. The nobility are all those who are above the degree of knight, and under which term is included that of a baronet; namely, dukes, marquises, earls, viscounts, and barons. 1 Black. 396.

Noturnal, nocturnalibus, an instrument chiefly used at sea, to take the altitude or depression of some stars about the pole, in order to find the latitude, and hour of the night.

Some nocturnals are hemispheres, or pianophores, on the plane of the equinoctial. Those commonly in use among seamen are two; the one adapted to the polar star, and the first of the guards of the little bear; the other to the polar-star, and the pointers of the great bear.

This instrument consists of two circular plates (see Plate Miscel. figure 173), applied to each other. The greater, which has a handle to hold the instrument, is about two inches and a half in diameter, and is divided into twelve parts, agreeing to the twelve months, and each month subdivided into every fifth day; and so that the middle of the handle corresponds to that day of the year wherein the star here regarded has the same right ascension. If the instrument is fitted for two stars, the handle is made moveable. The upper left circle is divided into twenty-four equal parts for the twenty-four hours of the day, and each hour subdivided into quarters. These twenty-four hours are noted by twenty-four teeth, to be told in the night. Those at the hour 12 are distinguished by their length. In the centre of the two circular plates is attached a long index, A, movable upon the upper plate; and the three pieces, viz. the two circles and index, are moved by a rivet which is pierced through the centre with a hole, through which the star is to be observed.

To use the nocturnal.—Turn the upper plate till the long tooth marked 12, is against the day of the month on the under plate; then, bringing the instrument near the eye, suspend it by the handle with the plane of the instrument parallel to the equinoctial, and viewing the pole-star through the hole of the centre, turn the index about till, by the edge coming from the centre, you see the bright star, or guard, of the little bear (if the instrument is fitted to it); and then that tooth of the upper circle, under the edge of the index, is at the hour of the night on the edge of the hour-circle: which may be known without a light, by counting the teeth from the longest, which is for the hour 12.

Node. See Surgery.

Nodes. See Astronomy.

Nollans, in church history, Christian heretics in the 3d century, followers of Nonius, a philosopher, Ephebus, who is said to have been named Moses, sent by God, and that his brother was a new Aaron; his doctrine consisted in affirming that there was but one person in the Godhead, and that the World and the Holy Spirit were both given to God in consequence of different operations; that as creator he is called Father; as incarnate, Son; and as descending on the apostles, Holy Ghost.

Nolana, a genus of the monograph order, in the pentadactyl class of plants, and in the natural method ranking under the 43d order, asperulae. The corolla is campanulate; the style situated between the gnemus; the seeds are biconvex, and resemble berries. There is one species, an annual of Peru.

Nolle prosequi, is used where the plaintiff proceeds no farther in his action, and may be as well before as after a verdict, and is stronger against a plaintiff than a nonuit, which is only a default in appearance; but this is a voluntary acknowledgment that he has no cause of action. Impey's B. R.

Nommhires, in heraldry, is the next below the fess-point, or the very centre of the escutcheon.

Name, or Name, in algebra, denotes any quantity with a sign prefixed or added. There are many more signs with some other quantity, upon which the whole becomes a binomial, trinomial, or the like: thus a + b is a binomial, a + b + c is a trinomial, whose respective names or names are a and b for the first, and a, b, and c, for the second. See Algebra.

Nominate, in grammar, the first case in nouns which are declinable.

Non-appearance, a default in not appearing in a court of judicature. Attorneys subscribing verbo copiosa for appearing in court are liable to attachment and fine for non-appearance. If a defendant does not appear and fill bate upon a scire facias and rules given, judgment may be had against him. Non compos mentis, in law, is used to denote a person's not being of sound memory and understanding. Of these persons there are four different kinds, an idiot, a madman, a lunatic who has lucid intervals, and a drunkard; the first two are defined by law, and the latter by his own act and deed. In all these cases except the last, one that is non compos mentis shall not lose his life for felony or murder; but the drunkard can have no innocence on his reason, for, in the eye of the law, his drunkenness does not extenuate but aggravate his offence.

Non est inventus, a sheriff's return to a writ, that the defendant is not to be found.

Non-naturals, in medicine, so called because by their abuse they become the causes of disease. See Medicine. The old physicians have divided the vices into 12 classes, viz. the air, meats and drinks, sleep and waking, motion and rest, the passions of the mind, the retentions, and excretions.

Non-pros. If the plaintiff neglects to deliver a declaration for two terms after the defendant appears, or is guilty of other delays or defaults against the rules of law in any subsequent stage of the action, he is adjudged not to pursue his remedy as he ought; and then upon a nonsuit or non prossequitur is entered, and he is then said to be non-prost. 3 Black. 395.

Non-residence. See Residence.

Nonagesimal, or nonageinal degree, in astronomy, the circumference of the midheaven, is the highest point, or 90th degree, of the ecliptic, reckoned from its intersection with the horizon at any time; and its altitude is equal to the angle that the ecliptic makes with the horizon at their intersection, or equal to the distance of the zenith from the pole of the ecliptic. It is much used in the calculation of solar eclipses.

Nonagon, a figure having nine sides and angles. In a regular nonagon, or that whose angles and sides are all equal, each side is 1, its area will be 6.1818324 ? 2 of 70°, to the radius 1.

Nonius. See Vernier.

Non suit, in law, is where a person has commenced an action, and at the trial fails in his evidence to support it, or has brought a wrong action. There is this advantage attending a nonsuit, that the plaintiff, though he pays costs, may afterwards bring another for the same cause, which he cannot do after a verdict against him. Todd's R. B. Practice.

Nones, nones, in the Roman calendar, the fifth day of the months January, February, March, June, July, August, September, November, and December; and the seventh of March, July, and October. March, May, July, and October, had six days in their nones; because these alone, in the antient constitution of the year by Numa, had 31 days apiece, the rest having only 29, and February 30; but when Cæsar reformed the year, and made other months containing 31 days, he did not allot them six days of nones.

Norroy, the title of the third of the three kings at arms. See Heraldry.

Normal, a perpendicular forming with another line a right angle.

Norway rat. See Mus. N. O. SE. See Anatomy.

Notarial acts, are those acts, in the civil law, which require to be done under the seal of a notary, and which are admitted as evidence in foreign courts.

Notary, is a person duly appointed by the laws of the several countries, in Canada and the United States, to attest deeds and writings, to receive and administer oaths and notes foreign and inland bills of exchange.
and promissory notes, translates languages and attests the same, enters and extends ship's protests, &c.

NOTATION, in arithmetic and algebra, the method of expressing numbers or quantities by signs or characters appropriated for their purpose. See ALGEBRA, ARITHMETIC, CHARACTER, &c.

Notation, in music, the manner of expressing, or representing by characters, all the different sounds used in music. The ancient notation is very different from that of the modern. The Greeks employed for this purpose the letters of their alphabet, sometimes placing them erect, and sometimes inverting, mutilating, and combining them in various manners, so as to represent by them all the different tones, or chords used in their system. By a treatise of Alpyus, professedly written to explain the Greek characters, we find that they amounted to no less a number than 1240. Those were, however, rejected afterwards by the Latins, who introduced letters from their own alphabet, A, B, C, D, E, F, G, H, I, J, K, L, M, N, O, P, fifteen in number, and by which they expressed the sounds contained in the bidental. The Greek improvement was to express the notation, which at length took place, and which is in part adopted at the present day, we are indebted to St. Gregory, the first pope of that name; who reflecting that in his diaspora, the bones of the lichnos meson, or the middle tone, were but a repetition of those which preceded, and that every septenary in progression was precisely the same, reduced the number of letters to seven, viz. A, B, C, D, E, F, G; but to distinguish the second septenary from the first, the second was denoted by the small, and not the capital, Roman letters; and when it became necessary to extend the system farther, the small letters were doubled thus, na, bb, cc, dd, ee, ff, gg. The stave, consisting of a variable number of parallel lines, the application of which some attribute to Guido, was afterwards introduced; and this was again improved upon by the use of a row of small points, commas, accents, and certain little oblique strokes, occasionally interspersed in the stave, while also two colours, yellow and red, were used; a yellow line signifying the F, and a red line signifying that of F. Two methods of notation were long after employed for the violin and other stringed instruments, which were distinguished by the terms lyra-way and gamut-way; with this exception, that the literal notation for the flute is constantly called the tablature; concerning which, as also the notation by letters in general, it may be observed that they are a very inartificial practice, as was also the old model of notation for the flute and flageolet by dots.

NOTE is a minute, or short writing, containing some article of business; in which sense we say, promissory note, note of hand, bank note. See Bills of Exchange.

NOTES, in music, characters which by their different forms and situations on the staves, indicate the duration as well as the gravity or accent of the several sounds of a composition.

NOTICE, in law, is the making something known that a man was or might be ignorant of before, and it produces divergent effects; for by it the party that gives the same shall have some benefit, which otherwise he should not have laid; and by this means the party to whom the notice is given is made subject to some action or charge, that otherwise he would not have been liable to, and his estate in danger of being distrained or persecuted. The plaintiff and defendant are both bound at their peril to take notice of the general rules of the practice of the court; but if there is a special particular rule of court made for the plaintiff, or for the defendant, he is not bound to whom the rule is made ought to give notice of this rule to the other; or else he is not bound generally to take notice of it, nor shall be in contempt of the court although he does not observe it. 2 L. P. R. 254.

NOTONECTA, a genus of insects of the order hemiptera. The generic character is, snout inflected; antenna shorter than thorax; wings coriaceous on the upper part, and crossed over each other; hind feet edged with hairs, and formed for swimming. The principal species of this are,

1. The notonecta glauca, a very common aquatic insect, inhabiting stagnant waters; and generally measured about three parts of an inch is length, and the lower wings are marked along the edges by a row of minute black spots. This insect is usually seen swimming on its back, in which situation it bears a most striking resemblance to a boat in miniature, the hind legs acting like a pair of oars, and impelling the animal at intervals through the water. It preys on the smaller inhabitants of the water, and flies only by night.

2. Notonecta sticta is much smaller than the preceding, not measuring more than a quarter of an inch in length, and is of a yellowish-grey colour, with numerous transverse unilunate black lines or streaks; it is found in stagnant waters.

3. Notonecta minuta, is an extremely small species, with grey wings, marked by longitudinal dusky spots; like the two former it is an inhabitant of stagnant waters, but is not so far less frequent, as it is readily observable by the eye, on account of its very small size. There are 17 species.

NOTOXUS, a genus of insects of the coelohera order. The generic character is, antennae three-making; labium long and broad; clypeus short and obtuse; jaw one-toothed; thorax a little narrowed behind. There are 13 species, found in Europe and Asia.

NOVIATIANS, a christian sect which sprang up in the third century; so called from Novatian, a priest of Rome, or Novatus, an African bishop, who separated from the communion of pope Cornelius, whom Novatian charged with a criminal lenity towards those who had apostatised during the persecution of Decius. He denied the church's power of remitting mortal sins.

NOVEL, in the civil law, a term used for the constitutions of several emperors, as of Justin, Theodosius, Leo, and more particularly for those of Justinian. The constitutions of Justinius were called novels, either from their producing a great alteration in the face of the ancient law, or because they were made on new cases, and after the revivification of the ancient code, compiled by the order of that emperor. Thus the constitutions of the emperors Theodosius, Valentinian, Marcian, &c. were also called novels, on account of their being published after the Theodosian code.

NOUS, in grammar, a part of speech, which signifies things without any relation to time; as a man, a house, sweet, bitter, &c.

NUCLEUS, in general, denotes the kernel or core of anything, which is separated within a husk. The term nucleus is also used for the body of a comet, otherwise called its head.

NUDE CONTRACT, a bare promise, without any consideration, and therefore void.

NUISANCE, signifies generally any thing that works hurt, inconvenience, or damage, to the property or person of another. Nuisances are of two kinds, public or private nuisance, and either affect the public or the individual. The remedy for a nuisance is by action on the case for damages. Every continuance of a nuisance is a fresh nuisance, and a fresh action will lie.

NUMBER, kinds and distinctions of: Mathematicians, considering number under a great many relations, have established the following distinctions. Broken numbers are the same with fractions. Carried numbers are those which exceed the quantity of units, as 1, 2, 3, &c. whereas ordinal numbers are those which express order, as 1st, 2nd, 3rd, &c. Compound number, one divisible by some other number besides unity; as 12, which is divisible by 2, 3, 4, and 6. Numbers, as 12 and 15, which have some common measure besides unity, are said to be compound numbers and having themselves a common measure.

Cube number is the product of a square number by its root; such as 27, being the product of the square number 9, by its root 3. All cubic numbers whose root is less than 6, being divided by 6, the remainder is the root itself; thus 27-54 leaves the remainder 3, its root; 216, the cube of 6, being divided by 6, leaves no remainder; 343, the cube of 7, leaves a remainder 1, which added to 6, is the cube root; and 512, the cube of 8, divided by 6, leaves a remainder 2, which added to 6, is the cube root. Hence the remainder of the divisions of the cubes above 216, divided by 6, being added to 6, always gives the root of the cube; the remainder of 343 and 512 divided by 6, leaves 5 and 3, respectively, and consequently 11 the cube-root of the number divided. But the cube number above this being divided by 6, there remains nothing, the cube-root being 12. Thus the remainders of the higher cubes are to be added to 12, and not to 6, till you come to 18, when the remainder of the division must be added to 18; and so on ad infinitum.

Determinate number, is that referred to some given unit, as a tarry or three; whereas an indeterminate one, is that referred to unity in general, and is called quality. Homologous numbers, are those referred to the same unit; as those referred to different units are termed heterologous.

Whole numbers, are other called integers. See INTEGER.

Rational number, is one commensurable with unity; as a number incommensurable with unity, is termed irrational or a surd. See SURD.

In the same manner a rational whole number, is that wherein unity is an aliquot part; a rational broken number, that equal to some,
If out of pentagons, first pentagonal pyramids.

1. From the manner of summing up polygonal numbers, it is easy to conceive how the prime polygonal numbers are found, viz. 

\[(a - 2) n^2 + 3n - (a - 3) \]

6

the prime pyramids.

Number in grammar, a modification of nouns, verbs, &c. to accommodate them to the varieties in their objects, considered with regard to number.

NUMERAL, those letters of the alphabet which are generally used for figures as I, V, X, L, C, D, M. See ARITHMETIC, Characters, &c.

NUMERALS, in grammar, those words which express numbers; as, six, eight, ten, &c.

NUMERATION. See ARITHMETIC, Characters, &c.

NUMIDA, in ornithology, a genus belonging to the order of galéorn. On each side of the head there is a kind of coloured plume. A bird that has been killed, and the flesh is worked with care near the nostrils. The species called melagris, or Guinea hen, is a native of Africa. See Plate Nat. Hist, fig. 298. It is larger than a common hen. Its body is very much like that of a turkey; its plumage is all over a dark grey, very beautifully spotted with small white spots; there is a black ring round the neck; its head is reddish, and it is blue under the eyes. They naturally herd together in large numbers, and breed up their young in common; the females taking care of the broods of others, as well as of their own. Barbut informs us, that in Guinea they go in flocks of 200 or 300, perch on trees, and feed on worms and grasshoppers; that they are run down and taken by dogs; and that their flesh is tender and sweet, generally white, though sometimes black. They breed very well with us.

The white-breasted one is a mere variety, of which there are many; it is mostly found in Jamaica. The mitred, or numida mitrata, is a different and not a common species; it inhabits Madagascar and Guinea. The third species which Mr. Latham mentions is the crested, or numida crestatus. This species likewise inhabits Africa. Buton, which describes it at great length, calls it pintado. Linnaeus and Gmelin call it Numida melचa, &c. Ray and Willughby call it gallus gallicus, Gmelin Guineensis, &c. Mr. Pennant considers, and seems to prove, that the pintado had been early introduced into Britain, at least prior to the year 1777. But they seem to have been much neglected on account of the difficulty of rearing in common; for they occur not in our ancient bills of fare. They have a double caruncle at the chaps, and no fold at the throat.

NUNCIO, or Nintio, an ambassador from the pope to some catholic prince or state; or a person who attends on the pope's behalf at a congress, or an assembly of several ambassadors. The nuncio has a jurisdiction and may delegate judges in all the states where he resides, except in France, where he has no authority but that of a simple ambassador. See Ambassador.

NUNCUPATIVE will, denotes a last will or testament, only made verbally, and not put in writing. See WILL and TESTAMENT.

NUMERICAL, in grammar, is a species of plants, cultivated for their beauty, their fragrance, and their fruit. The first number of this order is the rose, which is the symbol of love, and is the most admired of all flowers. The second number is the violet, which is the symbol of modesty. The third number is the tulip, which is the symbol of friendship. The fourth number is the lily, which is the symbol of purity. The fifth number is the orchid, which is the symbol of beauty. The sixth number is the magnolia, which is the symbol of grace. The seventh number is the daisy, which is the symbol of innocence. The eighth number is the chamomile, which is the symbol of peace. The ninth number is the violet, which is the symbol of modesty. The tenth number is the lily, which is the symbol of purity. The eleventh number is the orchid, which is the symbol of beauty. The twelfth number is the magnolia, which is the symbol of grace. The thirteenth number is the daisy, which is the symbol of innocence. The fourteenth number is the chamomile, which is the symbol of peace. The fifteenth number is the violet, which is the symbol of modesty. The sixteenth number is the lily, which is the symbol of purity. The seventeenth number is the orchid, which is the symbol of beauty. The eighteenth number is the magnolia, which is the symbol of grace. The nineteenth number is the daisy, which is the symbol of innocence. The twentieth number is the chamomile, which is the symbol of peace. The twenty-first number is the violet, which is the symbol of modesty.
The ground intended for the flower-nursery should be well situated to the sun; and defended from strong winds by plantations of trees, or by buildings. The soil also should be light and dry, especially for bulbous-rooted flowers; for in this nursery the offsets of all bulbous-rooted flowers should be planted, and remain there till they become blooming roots, when they should be removed into the pleasure-garden, and planted either in beds or borders, according to the goodness of the flowers. These flowers may also be raised in the nursery from seed. The seedlings auriculae, polyanthuses, ranunculus, amaranth, carnations, &c., should be raised in this nursery, where they should be preserved till they have flowered, when all those should be marked that are worthy of being transplanted into the flower-garden: this should be done in their proper seasons; for all these seedling flowers ought not indiscriminately to be exposed to public view in the pleasure-garden, because it always happens, that there are great numbers of ordinary flowers produced among them, which will then make but an indifferent appearance.

NUT. See Corylus.

NUT-GALLS. See Galls.

NUTATION, in astronomy, a kind of tremulous motion of the axis of the earth, whereby, in each annual revolution, it is twice inclined to the ecliptic, and as often returns to its former position. Sir Isaac Newton observes, that the moon has the like motion, only very small, and scarcely sensible.

NUTMEG. See Myristica.

NUTRITION. See Digestion, Material Medica, and Physiology.

NUX VOMICA, a flat, compressed, round fruit, about the breadth of a shilling, brought from India. See Stramonium.

NYCTANTHES, Arabian Jasmine, a genus of the monogynia order, in the dicotyledon class of plants; and in the natural method ranking under the 54th order, spermati. The corolla and calyx are actinoid: the perianth is dioc criminals. There are seven species, the most remarkable of which are: 1. The arbor tristis, or sorrowful tree. This tree, or shrub, the part of the Frangipani, grows naturally in sandy places in India, particularly in the islands of Ceylon and Java, where it is procured in great abundance, and attains the height of 18 or 20 feet. It rises with a four-cornered stem, bearing leaves that are oval, and taper to a point. The flowers, which are white and highly odorous, having a sweet delectable smell emulating the best honey, consist of one petal deeply divided into eight parts, which are narrower towards the stalk, and dilated towards the summit. The fruit is dry, capsular, membranaceous, and compressed.

It is generally asserted of this plant, that the flowers open in the evening, and fall off the succeeding day. Fabricus and Paludanus, however, restrict the assertion, by mentioning, from actual observation, that this effect is found to take place only in such flowers as are immediately under the influence of the solar rays. Grimmius remarks in his Laboratorium Ceylonicum, that the flowers of this tree afford a fragrant water, which is cordial, refreshing, and frequently employed with success in inflammations of the eyes. The tube of the flower, when dried, has the smell of saffron; and being pounded and mixed with sanders-wood, is used by the natives of the Malabar coast for imparting a grateful fragrance to their bodies, which they rub or anoint with the mixture.

2. The angustifolia, of which the flowers are white, inexpressibly fragrant, and generally appear in the warm summer-months. Strong loin is its proper soil.

NYMPH, among naturalists, that state of winged insects between their living in the form of a worm, and their appearing in the winged or most perfect state. See Entomology.

NYMPHÆA. See Anatomy.

NYMPHÆA, the water-lily, a genus of the monogynia order, in the polyandria class of plants; and in the natural method ranking under the 54th order, holorac. The hermaphrodite calyx is quinquepartite; there is no corolla; the stamina are five; there is one pistil; the fruit a plum inferior. The male calyx is quinquepartite, no corolla, and ten stamina. There are two species: 1. The integrifolia, entire-leaved, and 2. The dentilicata, or serrated-leaved tupelo.

The entire-leaved tupelo-tree, in its native soil and climate, grows to near 20 feet high; in this country its size varies according to the nature of the soil or situation. In a moist rich earth, well sheltered, it comes to near 20 feet; in others, that are less so, it makes slower progress, and in the end is proportionally lower. The branches are very numerous; and it rises with a regular trunk, at the top of which they generally grow. In England they seldom produce fruit.

The serrated-leaved tupelo-tree grows usually nearly 30 feet in height; and divides into branches near the top like the other. The leaves are oblong, pointed, of a light green colour, and come out without order on long footstalks. The flowers come out from the wings of the leaves on long footstalks. They are small, of a greenish-colour; and are succeeded by oval drupes, containing sharp-pointed nuts, about the size of a French olive.
the fourteenth letter of our alphabet.

As a numeral, it is sometimes used for eleven; and with a dash over it thus Ο', for eleven thousand. In the notes of the antients, Ω. CON. is read opus conductum; Ω. C. Q. opera consilique; Ω. D. M. opera, donum, munus; and Ω. L. O. opus localum.

In music, the Ω, or rather a circle, or double CO, is a note of time called by us a semi-breve; and by the Italians circulo. The Ω is also used as a mark of triple time, as being the numeral of all figures.

OAK. See Quercus.

OAKAM, old ropes untwisted, and pulled out into loose hemp, in order to be used in caulking the seams, tree-nails, and bends of a ship, for stopping or preventing leaks.

OAR, in navigation, a long piece of wood, for moving a vessel by rowing. Oars for ships are generally cut out of fir-timber, those for barges are made out of New England or Dantzick-oaken, and those for boats, either out of English ash, or fir rafters from Norway.

OAT. See Avena.

OATH, an affirmation or denial of any thing before one or more persons, who have the authority to administer the same, for the discovery and advancement of truth and right. See Affidavit.

OBEISAN, a truncated, quadrangular, and slender pyramid, raised as an ornament, and frequently charged either with inscriptions or hieroglyphs.

Obeisans appear to be of very great antiquity, and to be found traced to posterity precepts of philosophy, which were cut in hieroglyphical characters: afterwards they were used to immortalize the great actions of heroes, and the memory of personages. The first obelisk mentioned in history was that of Ramesses king of Egypt, in the time of the Trojan war, which was forty cubits high. Phurus, another king of Egypt, raised one of forty-five cubits; and Ptolemy Philopappus, another of eighty-eight cubits, in memory of Arian. Augustus erected one at Rome in the Campus Martius, which served to mark the hours on an horizontal dial, drawn on the pavement. They were called by the Egyptians the fingers of the sun, because they were made in Egypt also, to serve as dials or gnomons to mark the hours on the ground. The Arabs still call them Pharos's needles, whence the Italians call them aqua, and the French aiguilles.

The proportions in the height and thickness are nearly the same in all obelisks; their height being nine or nine and a half, and sometimes ten times, their thickness; and their diameter at the top never less than half, and never greater than three-fourths, of that at the bottom.

OBLATE, flattened, or shortened; as an oblate spheroid, having its axis shorter than its middle diameter, being formed by the rotation of an ellipse about the shorter axis.

OBLATENESS. See Earth, figure of.

OBLIGATION, a bond containing a penalty, with a condition annexed, either for payment of money, performance of covenants, or the like. This security is called a specialty. Co. Lit. 172. See Bond, and Deed.

OBLIQUE, in geometry, something slanting, or that deviates from the perpendicular. Thus, an oblique angle, is either an acute or obtuse one; that is, any angle except a right one.

OBLIQUE PLANES. See Dialling.

OBLONGATA MEDULLA. See Anatomy.

OBOLUS, in antiquity, an ancient Athenian coin, worth a penny farthing. Among ancient physicians; obolus likewise denoted a weight, equal to ten grains.

OBOLARIA, a genus of the angiosperma order, in the didynamia class of plants; and in the natural method ranking under the 40th order, personate. The calyx is bifid; the corolla campanulate and quadrifid; the capsule unilocular, bivalved, and polyspermous; the stamens rising from the divisions of the corolla. There is one species, a herb of Virginia.

OBSELYRATORY, a place destined for observing the heavenly bodies; being generally a building erected on some eminence, covered with a terrace for making astronomical observations.

The principal instruments for a fixed observatory are, a large fixed quadrant, or a circular divided instrument, chiefly for measuring vertical angles; a transit instrument; an equatorial instrument; a chronometer, or regulator; one or more powerful telescopes; a fixed zenith telescope; and a night telescope.

The quadrants, or quarter of a circle, divided into 90°, and each degree subdivided into minutes or smaller parts, has been made of various sizes; some of them having a radius even of eight or nine or more feet in length. When those quadrants do not exceed one or two, or at most three feet, in radius, they are generally fixed upon their particular stands, which are furnished with various mechanical contrivances, that are necessary to place the plane of the quadrant perpendicular to the horizon, and for all the other necessary adjustments. But large quadrants are fixed upon a strong wall by means of proper clamps; hence they have been commonly called mural quadrants, and are situated in the plane of the meridian of the observatory. In either of those quadrants an index, which reaches from the centre to the edge of the arch, moves round that centre, or round a short axis which passes through that centre so as to be moveable with its extremity all round that arc, and thus point out on the divisions of the arch, the angle which it forms with the horizon, or with the vertical line, in any given situation.

This index carries a telescope, through which the observer looks at any particular object, whose altitude he wishes to determine.

Plate Observatory, &c. fig. 1. represents a simple construction of a small moveable quadrant, and fig. 2. represents a mural quadrant. Of the quadrant fig. 1. CEI is the arc divided into 90°, and generally subdivided into smaller divisions, such as half degrees, or third parts of each degree, &c. The centre of the arch is at A, and the whole is connected together by means of strong metallic bars, as is shown between the letters ABC in the figure: in the centre A, a short axis is fixed perpendicular to the plane of the instrument, and to the upper part of this axis is fastened the index AD, which carries the telescope. This index generally has a small lateral projection, as at E, upon which the nonius or vernier is marked, by which means the minutes or smaller parts of each degree may be discerned. (See Vernier.)

The screw P, commonly called the tangent screw, with a nut that may be fastened to any part of the arch BC, screws likewise into the extremity of the index, and is useful for moving the index gently, or more accurately than by the immediate application of the hand to the index itself.

Since the index is suspended at one end, viz. at A, if the other end D happens to be disengaged from the screw P, the lower end D of the index will naturally come down to C, on account of its own weight, and that of the telescope. Now, in order to avoid this tendency downwards, an arm Y of brass or iron, is frequently affixed to the upper part of the index, which carries the leaden weight Z, sufficient to balance the weight of the index and telescope; so that by this means, even when disengaged from the screw P, the index will remain in any situation in which it may be left. The whole frame ABC is supported upon a strong vertical axis FS, the lower part of which turns into the pedestal OKM, and carries an index SX, which moves upon the divided horizontal circle O, fixed to the pedestal. This serves to fix the plane of the quadrant in any azimuth that may be required. The lower part of the pedestal has three claws, with a screw m in each; by which means the axis FS may be set truly perpendicular. The plummet AO, suspended at A, serves to show when the edge AC of the instrument is truly perpendicular, or when the first division of the arch at C is exactly in the vertical which passes through the centre A of the quadrant are BC. The weight of the plummet generally moves in a glass of water, which is fixed upon the arm GR; the object of which is to check the vibrations of the pendulum; which others we would be easily moved by every breath of air, and...
would continue to move for a considerable time after. We do not mention the bases of these screws, which are applied to read off the divisions at E and F, as the coincidence of the plummet-line with a dot marked upon the arc at C, as matters that need no particular description.

The eye-tube of the telescope, AB, there are certain slender wires, placed in the focus of the eyepiece, and perpendicular to the axis of the telescope, which enable the observer to distinguish more accurately when the object that is seen is through the telescope, reaches the axis of the telescope, or, as it is more commonly called, the line of collimation. Now, when the stars or planets are observed at night, those wires in the eye-tube cannot be seen; therefore, to render them visible, an arm or wire is fixed occasionally at the end of the telescope, which arm holds a small piece of ivory or card, set at the meridian of the eyepiece, so as to shine upon the aboved-mentioned ivory or card, the reflection of the light from it into the tube of the telescope will enable the observer to distinguish the wires at the same time that he beholds the celestial object.

The mural quadrant, fig. 2, is a larger instrument like the above, excepting that it has no stand; and its index is prevented from bending on account of its great length, by means of metallic bars, a, b, & c. This instrument is firmly fixed upon a wall exactly in the plane of the meridian of the observatory, for which purpose it has clamps, screws, and other adjustments. It has likewise a plummet.

This plummet is undoubtedly the principal instrument of an observatory; for by observing the times by the clock, of the arrival of any celestial object to the meridian, the right ascension of that object is had immediately; and its declination is shown at the same time by the index of the quadrant upon the divided arch; deducting the inclination of the equator, which is given by the latitude once ascertained of the observatory. It is by this means that exact catalogues of the places of the fixed stars have been made.

The transit instrument consists of a telescope of any convenient length, fixed at right angles to a horizontal axis, which is supported at its two extremities; and the instrument is generally situated so that the line of collimation of the telescope may move in the plane of the meridian. The use of this instrument is to observe the precise time of the celestial body's passage across the meridian of the observatory.

Fig. 3. exhibits a transit instrument. N M is the telescope; in the eye-tube of which are seen the wires, a, b, c, situated so as to divide the eye-lens. F E is the horizontal axis, in the middle of which the telescope is steadily fixed; so that by moving the telescope, the axis is forced to turn round its two extremities, A and D, which red to the notches of two thick pieces, T, S, of bell-metal, such as are delineated separately and magnified, at X and Z. Those pieces are generally fixed up on two pillars, either of cast iron, on which is better, or stone, as are shown in the figure; and they are constructed so as to be susceptible of a small motion by means of slips and screws, viz., the piece FF, which is fixed, and to which the axis of the circle is to be placed the telescope in the direction of any particular celestial body, when that body crosses the meridian; which inclination is equal to the collimation of the plane of the telescope, or the determination of the situation of the celestial body, according as that declination is north or south.

To adjust the clock by the sun's transit over the meridian.—Note the times by the clock, when the following parallel of the moon's limb touch the cross wires. The difference between the middle time and 12 hours, shews how much the mean, or time by the clock, is faster or slower than the time of right ascension, for that day; to which the equation of time being added, will show the time of mean noon for that day, by which the clock may be adjusted.

In the astronomical or equatorial sector, an instrument for finding the difference in right ascension and declination between two objects, the distance of which is too great to be observed by the micrometer, was invented by Hipparchus. A and B represent an arc of a circle, containing 10 or 12 degrees well divided, having a strong plate CD for its radius, fixed to the middle of the arch at D; the radius is applied to the side of the sector H I, and the instrument is so regulated that a joint fixed to it, so that the plane of the sector may be always parallel to the axis HI; which being parallel to the axis of the earth, and plane of the sector will always be parallel to the plane of some horary circle. Let a telescope CE be movable about the centre C of the arch AB, from one end of it to the other, by turning a screw at G, and let the plane of the horizon AB cut by the index at each transit; then in the difference of the arcs, the difference of the declinations, and by the difference of the times, we have the difference of the right ascensions of the stars.

The dimensions of this instrument are these: The length of the telescope, or the radius of the sector, is 24 feet; the breadth of the radius, near the end C, is 1½ inches; and at the end D two inches. The breadth of the limb AB is 1½ inches; and its length six inches, containing ten degrees divided into quarters, and numbered from each end to the other. The telescope carries a mosaic or subdividing plate, whose length, being equal to sixteen quarters of a degree, is divided into fifteen equal parts; which, in effect, divides the limb into minutes, and, by estimation, into smaller parts. The length of the square axis of the figures is eight inches.
and its thickness is about a quarter of an inch; the diameters of the circles are each 3 inches; the thickness of the plates, and the other measures, may be taken at the direction of a workman.

This instrument may be rectified, for making observations, in this manner: by placing the intersection of the hairs at the same or equal distance from the plane of the sector, as the centre of the object-glass, the plane described by the line of sight during the circular motion of the telescope upon the limb will be sufficiently true, or free from central curvature: which may be examined by suspending a long plumb-line at a convenient distance from the instrument; and by fixing the plane of the sector in a vertical position, and then by observing, while the telescope is moved by the screw along the limb, whether the cross hairs appear to move along the plumb-line.

The axis b f o (see figure below) may be elevated nearly parallel to the axis of the earth, by means of a small common quadrant; and its error may be corrected by making the line of sight follow the circular motion of any of the circum-polar stars, while the whole instrument is moved about its axis b f o, the telescope being fixed to the axis a for this purpose; let the telescope k l be directed to the star a, when it passes over the highest point of its diurnal circle, and let the division cut by the monis be then noted; then after twelve hours, when the star comes to the lowest point of its circle, having turned the instrument half-round its axis to bring the telescope into the position m n; if the cross hairs cover the same star supposed at b, the elevation of the axis b f o is exactly right; but if it is necessary to move the telescope into the position w z, in order to point to this star at c, the arc m n, which measures the angle m f o or b f o, will be known; and the axis b f o must be depressed half the quantity of this given angle if the star passed below o, or must be raised so much higher if above o; and thus the trial must be repeated till the true position of the axis is attained. By making the like observations upon the same star on each side the pole, in the six o'clock hour-circle, the error of the axis, towards the east or west, may also be found and corrected, till the cross-hairs follow the star quite round the pole: for, supposing a o p b c to be an arch of the meridian, make the angle a f p equal to half the angle a f c, and the line f p will point to the pole; and then the angle a f p, which is the error of the axis, will be equal to half the angle h f o, or m f o, found by the observation; because the difference of the two angles a f b, a f c, is double the difference of their bases a f o and a f p. Unless the star is very near the pole, allowance must be made for refractions.

Equatorial or portable observatory: an instrument designed to answer a number of useful purposes in practical astronomy, independently of any particular observatory; it may be made to serve all the purposes of the observatory and performs most of the useful problems in the science.

The principal parts of this instrument (fig. 3) are: 1. The azimuth or horizontal circle A, which represents the horizon of the place, and moves on axis b, called the vertical axis. 2. The equatorial or hour circle C, representing the equator, placed at right angles to the polar axis D, or the axis of the earth, upon which it moves. 3. The semicircle of declination, E, on which the telescope is placed, and moving on the axis of declination, or the axis of motion of the line of collimation F. These circles are measured and divided as in the following table:

<table>
<thead>
<tr>
<th>Measure of the various circles, and divisions on them,</th>
<th>Azimuth circle or hour circle</th>
<th>Vertical semi-circle, for declination</th>
</tr>
</thead>
</table>
| Radius divided to, when the telescope is in the declination-circle | 3° | 5 1
| Degrees, when the telescope is in the equator-circle | 1° | 5 1
| Measures of the several circles, and divisions in the declination-circle | 3° | 5 1
| Degree in time | 1° | 5 1
